Dr. Bewley exhibited a specimen of a cerebral tumour. The patient, a railway guard, had five severe epileptiform fits at intervals between June and November, 1907. He also suffered frequently from a feeling of tingling in the left forearm and leg. He was admitted into hospital in November. While in hospital the man complained of attacks of a tingling feeling in his left side, which was relieved by severe rubbing. He once got in hospital an epileptiform fit, beginning in the left arm. He never had a headache throughout, which was extraordinary. He never vomited once. He had no optic neuritis. Still, they could not help thinking that there must be a brain tumour on the right side of the brain, and from the frequency and pronounced nature of the attacks they thought it a cortical lesion, but the evidence in favour of localisation was not great. Knee-jerks were absent. There was no paralysis; he could walk very well, and was apparently in good health. He was admitted to hospital on November 14th, and went home for Christmas on December 24th. Four weeks afterwards he returned a good deal worse. There was almost complete paralysis of the left arm, and incomplete paralysis of the left leg, anæsthesia of the left arm and leg, and great drowsiness. The left side of the face was slightly paralysed. The drowsiness continued and merged into coma, and he died on February 11th comatose. Dr. Bewley hardened the brain by a method suggested by Dr. Leeper. He passed a large aspirating needle through the orbit and back into the sub-dural space, and through it poured in a quantity of formalin. The brain preserved its shape exceedingly well, and the sections exhibited showed the tumour clearly. The suspicion that it was a cortical lesion was not correct. It was an infiltrating glioma, and was interesting from the absence of the three cardinal signs of tumour and from the history of epileptiform seizures, and showed the difficulty of diagnosis in some cases of brain tumour.

Dr. LEEPER said the method to which Dr. Bewley had referred was taught to him by Professor Marie at Paris. He used it with satisfactory results in the case of insane persons who were a long time dying. He thought the epileptic seizures might have been due to multiple thrombosis. It was suggested that the blood of epileptics became more acid than normal, and that thrombi formed.

thrombi formed.

SEPTIC ENDOCARDITIS STARTING FROM CONGENITAL
PULMONARY NARROWING.

Dr. Bewley said the patient was a young man, aged thirty-two, who since childhood had been told that there was something wrong with one of the valves of his heart. He enjoyed good health until July or August last, when he began to suffer from chills and rigors. These recurred from time to time, and about September last he got some pleuritic trouble on his left side. When in Cork he suffered from pain in his right side, and Dr. Pearson, of Cork, found some

pleural trouble. He had a good deal of fever. Dr. Pearson found he had a loud systolic murmur heard all over the region of the heart, but specially loud over the second left costal cartilage. He thought he had a congenital narrowing of the pulmonary orifice. The patient was afterwards brought to Dublin and put under his care. He looked badly, and had some degree of irregular temperature. He has wasted a good deal. His liver was palpable, but seemed fairly natural in shape. A trace of albumin was present in the urine. He had a very slight cough. The diagnosis was not very clear. He (Dr. Bewley) thought it was probably general tuberculosis, but no tubercle bacilli were found on examination. possibility was that there was a concealed focus of of septic endocarditis. He did not himself think so, as there was no sign of emboli in the body. The patient became gradually weaker, and died in ten days. When the heart was removed he noticed that the two ventricles had approximately the same thickness in the muscular walls. The tricuspid orifice was slightly smaller than one would expect, and rather smaller than the mitral orifice. In the right ventricle he found a constriction about an inch and a half below the pulmonary valve. When they opened the pulmonary artery they found, starting from the constriction and growing up to the valves, which looked fairly healthy an anamous was a second to the starting from the constraints are constraints. fairly healthy, an enormous mass of vegetations. There was also a small opening in the septum between the ventricles. The left side of the heart and the aorta were perfectly healthy. They found scattered through the lungs a great many masses of infarcts surrounded by zones of inflammation; one or two were breaking down into little cavities. The diagnosis was a slow form of septic endocarditis, grafted on a congenital narrowing of the right ventricle just below the pulmonary orifice.

The Secretary said the sections of the vegetations under the microscope were crowded with microorganisms. There were present a diplococcus and a gram-staining bacillus. Inoculations from a very mixed culture-tube made from one of the infarcts killed two rabbits in the course of a few hours. He recovered two organisms from the animals. He was almost certain that the diplococcus was the pneumococcus, but he did not yet know what the bacillus was.

Dr. KILPATRICK asked if any attempt had been made to recover organisms during the patient's life.

Dr. Harvey asked if Dr. Bewley had any theory to account for the vegetations occurring on the right side of the heart, which might throw some light on the vexed question of why vegetations usually occurred on the left side. Did he think it was due to the extra force of the blood coming through, or had it anything to do with the aeration of the blood being altered by the communications between the auricles and ventricles?

The PRESIDENT asked if there was any evidence of infection of the general systemic circulation?

Dr. Bewley, in reply, said he only had charge of the case ten days, and during that time the patient was obviously dying. He could not find bacilli in the sputum, and he did not get any examination of the blood made. The condition might have been due to some roughness about the constriction and the increased force. He did not think there was any change of aeration. The pressure on both sides was probably much the same, so that there was evidently no free flow of blood between the two sides. All the other organs were healthy; he did not examine the brain. There was no trace of sepsis except in the lungs.

DUODENAL ULCER.

Dr. James Little exhibited a specimen. The patient was of the age, about sixty, when duodenal ulcers were, in his experience, most frequently seen, and he thought that nearly all he had seen had been in men, and he had seen more in private than in hospital practice. The man was well nourished and healthy-looking, but for five or six months he had been subject to abdominal pain which was in proportion to the solidity of the food he took. The pain

was rather to the right of the umbilicus. About ten days before admission to hospital he had two bleedings from the bowels, but he did not seem to think himself very ill. After three or four days in hospital he passed the half-full of a chamber vessel of hospital he passed the hair-full of a chamber vessel of bright-coloured blood, which looked as if it had come from the intestine not very far up. No trouble was found, however, in the rectum or descending colon. He had a further bleeding, and later he suddenly vonited for the first time a large amount of blood. On the same evening he had another large hæmorrhage, and died an hour or two afterwards. At the post-mortem they found a duodenal ulcer, and the cause of death was the rupture of an artery in the floor of the ulcer, which really was the head of the pancreas. He had never before seen death under the same circumstances. There was a second ulcer in the

The PRESIDENT asked if the man had exhibited any

symptoms of hunger-pain?

Mr. Wheeler said he had had five cases recently; one was verified by post-mortem and four by operation. All were past middle life, but none of the age of sixty. In four out of five duodenal ulcer was diagnosed chiefly on account of the hunger-pain which came on generally on the right side about four hours after food, and was relieved by eating something. Vomiting was irregular, and had no relation to food. In the fifth case the ulcer had perforated when the abdomen was opened, and was not diagnosed; the duodenum was practically rotten and leaking.

Mr. Stokes said Mayo found that 69 per cent. of

ulcers were duodenal, and in males the proportion was still higher. Gastric ulcer was rather commoner in females. The hunger-pain was found in any lesion

of the middle gut.

Dr. Moorhead said that in two cases of duodenal ulcer he had seen, one in a woman, aged fifty, the typical hunger-pain was present. The ulcer was found by operation, and a complete cure effected. The other case was a young man, aged twenty-two, who never had the hunger-pain. He had symptoms of perforation, and a perforated duodenal ulcer was found on

Dr. CAHILL said the age-limit was probably the final crisis after a chronic trouble of many years, so final crisis after a chronic trouble of many years, so that duodenal ulcer began much earlier than was usually thought. The hunger-pain was found in several other conditions. A definite time-relation could be found by giving the patient something indigestible, like pork, to delay the pain.

Dr. LITTLE, in reply, said he had no doubt that the hunger-pain was clinically important, but it was certain that it was not so pathognomonic as it was supposed to be

supposed to be.

TUMOUR OF BRAIN.

Dr. LITTLE also exhibited a specimen of cerebral tumour taken from a girl, seventeen years of age. She had come to hospital about ten days ago, having sickened and vomited on the Friday previous to the Tuesday on which she was admitted. On the Sunday she became unconscious. She was unconscious on admission, and appeared to have paralysis of both sides of the body. She had very strongly contracted pupils, and, remembering a similar circumstance in a case many years ago, he made a diagnosis of a pons lesion. He made a post-mortem, and in the centre of the pons he found a hæmorrhage as big as a marrowfat pea.

Professor Scott said it was a pure hæmorrhage, but not of an ordinary type. Nearly every artery appeared to have weakened walls, and the apparent tumour was made up of innumerable discrete hæmorrhages.

STENOSIS OF TRICUSPID AND MITRAL ORIFICES.

Dr. Coleman exhibited a heart with stenosis of tricuspid and mitral orifices. The patient was a girl about twenty-four. She had a history of attacks of rheumatic fever. She was admitted to hospital about six months ago, and died in five months. The prominent symptoms were dyspnœa, cyanosis, and some cedema, and two or three weeks before she died she had embolism of the right femoral artery, and in the case of the brachial artery the nutrition of the

limb was retained, but she got gangrene up to the knee in the right leg, and amputation was performed. He diagnosed mitral stenosis from the physical symptoms. An unusual point was that the presystolic murmur was heard over a more extensive area than usual. A thrill was present, but only over the mitral area. She was found at the post-mortem to have well-marked mitral stenosis. The mitral orifice was reduced to a mere slit, and she had considerable stenosis of the tricuspid. In addition she had recent vegetations on the aortic cusps.

Dr. Bewley and Dr. Little recalled similar cases.

HARVEIAN SOCIETY OF LONDON.

MEETING HELD AT THE STAFFORD ROOMS ON FEB. 18TH, 1909.

DR. E. GRAHAM LITTLE read a paper on "Ionisation in the Treatment of Skin Diseases," a full abstract of which will be found on page 244 of our present issue.

Dr. LANGMEAD read a paper on "Infant Feeding by Undiluted Citrated Milk," which is published in full

on another page (see page 241).

The following members took part in the discussion:

Sir Almroth Wright, Dr. Davis, Dr. Willcox, Dr.

Miller, Dr. Payne, Dr. Turtle, Dr. Finny, and Mr.

Laming Evans.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD FEBRUARY 25TH, 1909.

The President, T. H. BICKERTON, in the Chair.

THE PRESIDENT referred to the loss to the Institution by the recent deaths of Prof. D. J. Hamilton, of Aberdeen; Drs. G. E. Walker and J. Tawse Nisbet, of deen; Dis. O. E. Walket and Liverpool; and Dr. H. W. King, of Chester; and expressed sympathy with their families.

Mr. R. C. Dun read a note on

THREE CASES OF CONGENITAL RECESSES OF THE LOWER LIP.

The condition in each case was associated with double hare-lip and cleft palate. No family histories of congenital deformities could be ascertained, nor were any other children of the families afflicted.

Case 1.—Two symmetrically placed recesses were present on either side of the middle line of the lower lip, which was thickened and everted. From them sinuses ran downwards in the substance of the lip, ending blindly under the mucous membrane on its inner aspect. The sinuses discharged a mucous secretion.

CASE 2 .- A similar condition was present, but with, in addition, papillæ at the orifices of the sinuses. Movements of protrusion and retraction were seen in

CASE 3 was most unusual, only one similar having been previously reported. Instead of two sinuses, there was present a single slot-like cavity in the lower lip. I in. in length, and I in. in depth. This child lip, 1 in. in length, and 1 in. in depth. This child also showed a deformity consisting of a fold of mucous membrane passing from the inner aspect of the lower lip close to the angle of the mouth on either side, to be attached to the alveolar margin of the upper jaw. Misplaced testis and torsion of the penis were also present in this case.

Mr. Dun reviewed the various theories which had been advanced to explain the presence of congenital diseases of the lower lip. None of them would adequately account for the mode of origin of the three different types of the deformity which had been met with. The condition was a rare one, only 38 cases having been previously reported. The note was illus-

trated by lantern slides.

Mr. Frank Jeans mentioned a case of congenital depressions, fistulæ in the helix. In the case of the auricle these potential dermoids had a definite developmental explanation.

The note was also discussed by Mr. R. W. Murray and Dr. Blair Bell.

Dr. Briggs read a paper on the SPONTANEOUS RUPTURE OF CYST-ADENOMATOUS OVARIAN TUMOURS,

in which he urged (1) that the primary cause of cyst rupture in cases of ovarian cyst-adenoma, is tumour degeneration (necrosis); (2) that the rarity of cyst rupture in relation to the frequency of tumour degeneration is not inconsistent with the adequate, vascular compensation almost invariably supplied by adhesions to the degenerated tumour; and (3) that

these adhesions are simply reparative, and are not, as generally stated, the result of peritonitis.

The innocent leakage through attenuated and thin cyst walls as a common and normal occurrence is excluded from the rare rupture: on the absence in the former, or on the presence in the latter of clinical

manifestations is based a working distinction.

Cyst rupture as an appreciable clinical and pathological complication is one of the accidents in a case of an ovarian cystic tumour, and just as in a case of accidental hæmorrhage during pregnancy, trauma or violence in the history of its causation is almost invariably wanting.

From the earlier and darker days of ovariotomy the records of 66 and 80 tappings of an ovarian cyst leave no doubt as to the healing power of the normal cyst wall.

He quoted, from Meredith and Spencer Wells, evidence as to the vital activity and resistance of the peritoneum and to the absence of adhesions after tap-

Where there are neither infective organisms nor loose particles of growth capable of implantation, he argued that intra-peritoneal cyst rupture—at the time unattended by serious hæmorrhage—is of itself a harmless, or almost harmless, pathological process. On the other hand, degeneration of the cyst produces a permanent opening, and a continuous dribble of cyst contents without any barrier of defence such as is provided by the hæmatocele sac around a chronic tubal

drip in a case of tubal mole.

Where adhesions are universal around both innocent and malignant tumours, and after torsion of the pedicle, hydroperitoneum is invariably absent, and rupture is counteracted.

Dr. Briggs also narrated four cases of cyst rupture which occurred in his own practice, and submitted the following brief analysis from them:—In non-malignant following brief analysis from them:—In non-mangnant cyst-adenomata the clinical manifestations are (a) of tumour degeneration: (1) impairment of health disproportionate to the size of the tumour; (2) abdominal pain; (3) variable distension of the abdomen; (4) irritability of the bladder (5) irregular menstruation, subject to the usual modifications of pregnancy, lacting and the climateric. (b) Of runture of the cyst: tation and the climacteric. (b) Of rupture of the cyst: acute pain; recurrent pain; vomiting; the accumulation, at a variable rate, of free fluid in the abdomen.

The diagnosis of cyst rupture by free intra-peritoneal fluid can only be (1) Positive, when the partially filled cyst can be felt, or when the previously firm cyst has completely collapsed; (2) presumptive, when the clinical manifestations of degeneration and rupture have been obtained; and (3) occasionally and exceptionally, when the free fluid is small in quantity and the gustive minutes both many cases. and the rupture minute; both may escape detection before and during the operation of ovariotomy. The modern preference for removal of the tumour entire, if practicable, accounts for a long incision in Case 4, whereby both the 20 oz. of free intra-peritoneal mucoid fluid and the dribble through the small aper-

ture of rupture were exposed to view.

The teaching of Matthews Duncan that, although the diagnosis of an ovarian tumour approaches practical certainty, it is not one of scientific precision, applies also to the recognition of complications.

The ovarian tumours of small size and the largest of only moderate size in his series of ruptured cysts had impaired the health of the patients to extents unusual for the size of each growth. Not one was malignant. The general peritoneum, so far as it was visible, was only changed in one—Case 1—in which it was injected and thickened, but not shreddy.
Finally, Dr. Briggs compared the mechanical influ-

ence, the loss of fluid, and the degenerative changes

in ovarian growths to their respective effects upon the general nutrition of the patient.

He argued that the benefits the patient often experienced during temporary recumbent rest were more consistent with degenerative changes than with progressive tumour growth in cases where inflammatory complications were absent.

The paper was illustrated by lantern slides and specimens.

The paper was discussed by Dr. BLAIR BELL. He had operated on two cases. He thought diagnosis should be easy, and prognosis good. He regarded it as a rare condition. Degeneration of the cyst wall, traumatism, or violent exertion might produce it.

"KISSING THE BOOK."

Dr. F. W. LownDES read a paper on "Kissing the Book." He gave personal recollections of 43 years' experience in various judicial courts. He gave instances of the insanitary and dangerous nature of the English. method of taking the oath, which had been clearly proved to have caused disease in two cases, while this was only an infinitesimal proportion of the real number which it would be very difficult to trace. He urged the abolition of the use of the "Book" and the substitution of the uplifted hand.

While discussing the paper, the PRESIDENT proposed the following resolution:—"That this meeting is of the opinion that the custom of kissing the Book on taking an oath is insanitary and dangerous, and should be abolished, and the form of administering the oath with uplifted hand be adopted."

The resolution was seconded by Mr. R. W. MURRAY. and carried unanimously.

The paper was also discussed by Drs. Gill, T. R. Bradshaw, F. Barendt, A. G. Gullan, Sullivan, and W. B. Warrington, and Mr. Damer Harrisson.

Dr. Lowndes replied.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD MARCH 5TH, 1909.

Dr. RUTHERFURD in the Chair.

THE members were treated to a very extensive exhibit of specimens of diseased conditions.

Dr. W. K. HUNTER read notes of a fatal case of leukæmia in a child, 5 weeks old. The liver and spleen were greatly enlarged, and the blood had undergone serious changes, there being a great increase of mono-nuclear leucocytes, while the red blood corpuscles were greatly reduced in number, varied greatly in size and in staining power.

Dr. MUNRO KERR showed a large tumour of the kidney (hypernephroma), removed by abdominal route. He also showed an interesting specimen of cancer of the sigmoid, removed with the rectum by the combined abdominal and perinæal routes.

Sir George Beatson exhibited a beautiful series of colour drawings illustrating types of diseased appendix, some with stricture, concretion, etc.

Dr. T. K. DALZIEL showed a man on whom he had performed a brilliant operation for malignant disease of the tongue and pharynx. Most of the tongue had been excised, with one tonsil, the corresponding pillars of the fauces, and part of the pharynx. All the glands below the jaw were taken away; and in a second operation Dr. Dalziel completed his successful operation by removing the rest of the cervical glands down to the clavicles. A tracheotomy tube was used as part of the technique of the operation.

Interesting specimens were exhibited by Dr. Archibald Young, Dr. John H. Teacher, Dr. Pringle, and others.

GLASGOW EASTERN MEDICAL SOCIETY.

MEETING HELD MARCH 3RD, 1909.

The President, Dr. MATHIE, in the Chair.

A VERY interesting lecture, "Demonstration on Some

of the Enlargements of the Kidney, with Reference to Diagnosis," was given by Dr. John Anderson, Pathologist to the Victoria Infirmary. Dr. Anderson referred to three lines that were useful for diagnostic purposes. These were: Gairdner's line—a line drawn from the left axilla to the umbilicus. Normally there should be resonant percussion in this line. In marked enlargements of the spleen there would probably be dull percussion advancing across Gairdner's line. A more useful line, according to Dr. Anderson, was Litten's line—a line drawn from the sterno-clavicular articulation to the tip of the 11th rib. The normal splenic dulness was posterior to this line, and any decided enlargement of the spleen would cross this boundary and give rise to dull percussion. Another useful line was Addison's—namely, a line encircling the body mid-way between the supra-sternal notch and symphysis pubis. Dr. Anderson pointed out that one-flird of the kidney lies above Addison's line, and that the pancreas and the duodenum have a definite relation to the line. He stated that normally the supra-renal capsules have an inward inclination.

Among the specimens exhibited were cancer of the kidney, tuberculosis of the kidney, hydro-nephrosis, and cystic disease of the kidneys. In congenital cystic disease of the kidneys the organs may reach a large size, and the patient live on to middle life, be unaware

of his disease, and die of uræmia.

#### CORRESPONDENCE.

#### FROM OUR SPECIAL CORRESPONDENTS ABROAD.

#### FRANCE.

Paris, March 7th, 1909. EAR-RINGS.

THE desire to adorn the face by means of objects of gold and silver, appended to the ears, dates, it would appear, from the highest antiquity. Ear-rings or pendants have been found in nearly every sepulchre; those of the bronze age were distinguished by the size and weight of the rings.

Among certain peoples, ear-rings were used as a means to give a certain form to the organ to which they were appended. The Chinese, for instance, pierce the ears to suspend heavy objects in order to render them long and pendant. The inhabitants of Laos make the long and pendant. The limitabilities of Labs make the hole so large that one or two fingers can be passed through it. The Omagnas carried a bouquet of flowers in their ears, thus perforated.

Beauty is, after all, purely conventional, and, as regards the ears, we can ill afford to criticise, we who

without knowing very well the reason why, cut dogs tails short or leave them long, as fancy seizes us to obey some æsthetic whim which varies with the race of the canine species.

From a medical point of view the wearing of earrings, as well as the preliminary piercing of these organs, can provoke accidents or maladies.

Dr. Lucas-Championniere published different cases in which the modern screw button produced disorders rendering an operation necessary. Dr. Nicolas relates the case of a distinguished young lady in whom a diamond solitaire screwed into the lobe of the ear had produced inflammation of the region, and was buried in the tissue. An incision was necessary to extract the solitaire, and the parts took a month to get well.

Affections following the little operation of piercing the lobe have been frequently reported. The majority of these accidents are benign, and belong to the group of cutaneous maladies, but others, on the contrary, may be grave and result, as has been more than once noticed, from inoculation of tuberculosis or syphilis.

According to Dr. Leon Perrin, impetigo, among the

skin diseases, is the most frequently observed. Pustules form around the perforation, which, by successive inoculations, may spread to the face, neck, or head. Cervical adenitis or otitis of the middle ear may even complicate the situation.

Eczema is also observed from perforation of the lobes in children, with seborrhæa of the head. It persists a long time, and may invade the face.

Constantin Paul says that he was struck with the fact that such a slight traumatism could give rise to phenomena inherent to the constitution of the child or the adult. He himself pierced, with all the desired precautions, the ears of a young girl of his own family who up to then apparently enjoyed the best of health. Yet afterwards the little wound provoked a crop of herpes which returned every year.

Cheloids of the lobe have been observed by several authors. Perrin cites a case of a cheloid situated behind the lobe, and which at the end of the year acquired the size of a nut.

Fournier and Chaunau recently reported a series of accidents due to the piercing of the ears, among which may be mentioned erysipelas, gangrene, and inflammation of the mouth.

Leloir observed a case of tuberculous lupus in a young girl of twenty. It began shortly after a jeweller of the town had pierced the ears of the patient. Hitherto the young girl was of an excellent constitu-tion, and none of her family suffered from tuberculosis, but the jeweller who performed the operation was phthisical, and died of that malady.

Prof. Unna, of Vienna, relates a particularly grave case of contagion: A young girl, æt. 14, of a perfectly healthy family, wore earrings which belonged to a healthy family, wore earrings which belonged to a friend who had died a short time before from consumpton. Some months afterwards the girl fell ill; ulceration appeared on the lobes of the ears; the glands of the neck became engorged, while the presence of tuberculous bacilli was observed in the granulation of the auricular ulceration. Bronchitis set in, and the patient rapidly succumbed to tuberculosis. Barthelemy relates a similar case.

Even syphilis has been proved to have been contracted from this operation. Prof. Fournier related four typical cases in his work on syphilis. Dr. Le Ray reported, some years ago, a case of a young girl of ten who presented mucous patches in the throat and the characteristic eruption on the body as a result of contamination through the trocar of a jeweller who had the disease.

The knowledge of these different accidents-cutaneous, tuberculous, or syphilitic—should inspire, says Dr. Muller, certain prophylactic measures. The jewellers should be forbidden the right of piercing ears, or at least they should be warned of the danger to which they expose the child by employing septic instruments or using the same instrument indiscrimi-nately for a number of children, some of whom might

be suffering from contagious affections.

The operation should not be practised except between the age of 12 and 25 years, the production of eczema and impetigo being very easy in young children.

Abstention should be preferred in scrofulous or lymphatic children, for fear of lupus or tuberculosis.

The best prevention, need it be said, would be to banish this useless custom for ever. Our grandmothers had some excuse; they believed that the wearing of pendants, sleepers, and rings preserved the children from maladies of the eyes. To-day faith in this intervention is lost except in certain countries, where even the men wear little gold rings in their ears.

The Greeks and Romans, good judges of feminine

beauty, did not esteem the ear-ring indispensable to it. The brushes or chisels of the immortal Greek artists did not represent any paintings or statues with ear pendants.

On the other hand, these pendants were inflicted by the Romans on the vanquished as a mark of servitude. COLLOIDAL METALS.

The action of colloidal metals on local infections and diseases of nutrition has been proved to satisfaction.

Albert Robin observed that pneumonia is the disease in which the treatment by colloids appears to be particularly indicated, as it provokes all the phenomena of reaction; it diminishes notably the duration of the malady and at the same time the mortality. The brilliant success obtained by intra-rachidian injection of collargol in cerebro-spinal meningitis has not been forgotten. These injections were attempted for the first time by MM. Caussade and Joltram. M. Rosenthal and Mile. Joffe cured an inveterate drunkard suffering from cerebral rheumatism by injections of electrargol. Numerous have been the cures of peritonitis, general or puerperal, by injections of colloid silver. Dr. Massin, of Nice, employs with success injections of electrargol for purulent otitis. To this list might be added affections of the urinary passages, pleurisy, phlebitis, etc.

GRRMANY.

Berlin, March 7th, 1909.

Herr Busc At the Freie Vereinigung der Chirurgen Herr Busch said that during the last four years at the surgical department of the Urban Hospital he had met with 22 cases of sudden death from cardiac disease. Twelve of these took place so rapidly that there could be no question of any operative procedure, such as had been proposed by Trendelenburg. In the remaining ten the period of time between the commencement of the attack and death varied from ten minutes to three hours, the average being 30 minutes. The autopsies showed that there was pulmonary embolism in only five cases, in the others the grave form of myocarditis was present, or brown atrophy of the heart. Clini-cally these cases were not distinguishable from the other five, so that a diagnosis of pulmonary embolism was at the least very uncertain. At the autopsy on the case that lived longest Körte performed an operation exactly according to the directions of Trendelenburg. At it he removed a thrombus, which, however, was a cadaveric one, whilst the whole mass of that that had formed during life remained behind in the vessels.

Herr Körte pointed out that of the cases that had to be diagnosed as embolism of the pulmonary artery many pulled through with difficulty, so that it was extraordinarily puzzling to fix upon the exact

indication for operation.

Herr Körte said that during four years he had performed 152 choledochotomies in a total of 237 gall-stone operations, most of them complicated with cholecystectomy. One was a case of carcinoma of the papilla Vateri, that had been operated on two and a half years earlier, and in spite of the bad prognosis in these cases the patient recovered and remained free from recurrence. The classical symptoms of biliary colic were by no means always present: jaundice, colic, small contracted gall-bladder. Jaundice was absent in 25 per cent. of the cases, and on the other hand jaundice and acholia of the stools were present without stones in the duct. Colic also might be absent, then there were only attacks of fever with great prostration, and slight jaundice. It was just in these cases that operation should not be long delayed, or it did no good. The gall-bladder also was not always contracted. Even in case of a large gall-bladder, a careful inspection of the bile passages was indispensable.

In a total of 142 gall-duct operations he had had five deaths: 3.5 per cent. If to these were added 10 cases in which there were complications, there was a total of 152 cases with 8 deaths: 5.2 per cent.

He had laid down the principle never to approach these cases with his mind made up, but to follow up the whole biliary system, and search for the calculi

in whatever corner they were secreted.

After a paper on umbilical hernia by Hr. Ruge, After a paper on umbineal nernia by Hr. Ruge, Hr. Brentano showed a young woman, æt. 24, whose rectum he had resected for a space of 27 cm., for papilloma; she had suffered from hæmorrhage and mucous discharges from the bowel. In spite of the extent of the removal, some polypi still remained, an experience that again taught how little surgery could do in these cases. could do in these cases.

A girl, æt. 19, had tracheotomy performed on account of severe dyspnæa; even before this a tumour below the vocal cord had been diagnosed, the mucous membrane over it being intact. Five days after the tracheotomy the larynx and cricoid cartilage were split, and the tumour removed. It proved to be an intratracheal struma.

A man of middle age was taken ill with abdominal A man of middle age was taken ill with abdominal pains, particularly in the upper part, collapse and symptoms of peritonitis. The speaker decided that the case was one of acute pancreatitis, and he was confirmed in this opinion by a distinct resistance appearing in the course of a few days, in the bulging epigastrium. He made an incision in the median line, as well as counter incisions in both flanks, and obtained a large quantity of chocolate-coloured fluid, but no fat necroses. For a long time pancreatic juice but no fat necroses. For a long time pancreatic juice emptied out of the wound, transient sugar was found in the urine. Of six similar cases that he had operated on four had recovered.

### AUSTRIA. Vienna, March 7th, 1909.

ATTIC CHOLESTEATOMA.

At the Gesellschaft der Aerzte, Barany presented a woman, æt. 30, from whom he had repeatedly removed cholesteatoma and polypi from the middle ear. The difficulty of removing these from the antrum while endeavouring to retain the epidermis covering the stapes and hammer was finally accomplished, but, unhappily, was followed by the formation of a granuloma over the stapes, which had to be removed, and left a rent in the tympanum. After this the patient suffered from vertigo with fistula of the labyrinth, as the typical rotatory nystagmus of both eyes was painfully present. That fistular symptom has now disappeared, and the open wound over the stapes quite closed up.

The peculiarity in this case was the wonderful functional result, the hearing being as good now as ever, after so much damage to the tympanum and

injury done to the stapes and hammer.

LYMPHANGIOMA OF ORBIT.

Bergmeister next exhibited a child, set. 23, with a thick upper left lid, due apparently to an ill-defined soft swelling extending under the skin to the temporal region. The swelling was somewhat compressible, but not affected by that to-and-fro movement by compressing the jugular. The bulbus of the eye was not protruding, but, on the contrary, was sunken in the socket. The fundus of both eyes was perfectly normal. In addition to this, there were a number of pigmentary patches over the breast and back.

According to the theory propounded by Recklinghausen, this is the first symptom of neuro-fibromatosis in the cutaneous nerves. This neuro-fibroma, sometimes known as Ranken's neuroma, is difficult to distinguish clinically from lymphangioma, as both are

depending on the same anatomical process.

LYMPHO-SARCOMATOSIS.

Siegfried brought forward an old man, æt. 74, suffering from a diffuse, reddish-blue erythema covering the head, among the hair, neck, and body, as low as the breast, where it formed a sort of arc between the mammillæ. At first it was recognised as a lichenoid exanthema, till closer observation of the cedema, which was very insignificant, the coold, confluent efflorescence, itching, and localisation of parallel nodules attracted attention. Further examination revealed large hard glands in the supra-clavicular region on both sides of the body in the axilla, as well as hard, cedematous skin on the left side of the thorax.

The cause of the false diagnosis was due to the bilateral presence of the morbid change, which is a rare condition in lympho-sarcoma, though common enough

in lichenoid dermatosis.

CONTRACTION OF SECOND PHALANX.

Lotheissen showed a patient on whom he had operated for contraction of both little fingers, which became stiff about the eleventh year of age without any apparent cause. He first made an N-incision, dividing the skin over the muscula interossei and lumbricales, forming two triangular flaps. Having done this, he found the finger could not be straightened. He next resolved to divide both angles of the aponeurosis, which in this case was much wider, but shorter than the

normal, and thus relieved the contraction. He considered this equal to Dupuytren's contraction of the palmar aponeurosis, which appears to have originated in a chronic plastic inflammation. The patient is now able to move his fingers freely both in extension and contraction. He considered the operation necessary in these cases when the deformity interfered with work

Klein thought many of these contractions were hereditary, like retinitis pigmentosa, which had always a family history. Tandler remarked that these cases of contraction of the little fingers were not uncommon if the statistics of the post-mortem room are to be credited. He has frequently met with it, and agrees with Lotheissen that the deformity is due to the aponeurosis being shortened, which prevents the proper extension of the fingers.

Schlesinger said that he had seen contractions in the little fingers for three generations in one family history. The rule was an abnormal shortening of the fingers and a shrinkage of the phalanges.

COPPER SULPHATE POISONING.

Pollak showed a female, æt. 20, who had attempted to poison herself by drinking a solution of 10 grains of sulphate of copper. Severe vomiting of a blue fluid followed. The stomach was washed out, but soon after this icterus, somnolescence, severe pain in the epigastrium and region of the liver, with anæmia of the mucous membrane, albumin, and blood in the urine, set in. Great anæmia was present after the icterus had disappeared, but a few days later the patient returned to her normal condition.

#### HUNGARY.

Budapest, March 6th, 1909. At the recent meeting of the Budapest Royal Medical Society, Dr. Balint read a paper on FUNCTIONAL RENAL DIAGNOSIS.

He said that opinions are still very much divided concerning cystoscopic renal diagnosis, and enthusiastic reports alternate with more conservative articles. Dr. Balint's paper belongs to the latter class, for he had some experiences which make him doubt that absolute reliance in the method is safe. The character of the food and the amount of fluid ingested seem to have a marked influence upon the freezing point, but even if the diet is simple and absolutely uniform the figures vary within very wide limits. Several cases are reported, he continued, where the wrong kidney would have been extirpated, if the molecular concentration alone had been taken into consideration. Much more satisfactory results are obtained if attention is also paid to the daily amount of urine and if renal activity is expressed in so many daily molecules. In all cases the diet should be controlled, and the catheters should be introduced a definite period after a meal and left in position for at least two to three hours, since fluctuations are very common. At best the method is only approximate, but though troublesome, it offers valuable aid in conjunction with other data.

Dr. Sellei discussed the
Value of X-Rays in Circumscribed Peri-urethral
Gonorrhæa.

The utility of the X-rays, he said, as a diagnostic
agent in urology is well recognised. Therapeutically, however, in the diseases common to this special branch of medicine, they have made but limited progress. Sellei described the *technique* at Budapest in three cases of peri-urethral infiltration. The intensity of the current was three to four ampères. The tubes were No. 3, and moderately hard. The exposure period was ten to fifteen minutes. In the first exposure a piece of sheet lead was used (as done by Kaufmann however, in the diseases common to this special branch a piece of sheet lead was used (as done by Kaufmann in Frankfort) to shut off the parts intended to be protected. Later, however, a lead cylinder was used. The distance from the tube varied from 10 to 20 cc. Sellei reported from three cases in detail. They were each of cavernous infiltration, which had resisted ordinary forms of treatment. He does not claim that the rays are a panacea in the treatment of this condition or even that they destroy bacterial life. It is apparent that they are a very decided factor for good,

however they may work, whether by direct destruction of the bacteria or by causing the absorption of the inflammatory tissues. Three cases are not sufficient upon which to base any conclusions, but it would appear that the disorder is sufficiently superficial to lend itself favourably to this form of therapy. INFLUENCE OF WEATHER CONDITIONS ON MORTALPTY.

According to the bulletin of the Health Department for the month ending December 31st, the influence of the weather conditions of the last three weeks (in December) is already being reflected in the bills of mortality. The death-rate for the month is 12.5 per cent. higher than that of the previous month, and previous ten years. An analysis of the figures in the statement of mortality indicates clearly that the weather and exposure to it at outdoor sports, in Christmas shopping, at skating, is made responsible for the increase. Owing to the incidental tramway strike, deaths in consequence of fractures, etc., were on the increase. Thus, there is a 12 per cent. increase in the deaths among the aged—those over sixty years. Deaths from the chronic diseases show increases of 10 per cent. each for consumption and heart diseases, of o per cent. for Bright's disease, 12 per cent. for cancer, and 60 per cent. for diseases of the nervous system. The death-rate may be expected to increase during the succeeding months, January and February, and therefore even the lay papers warn the public that "those suffering from common colds, catarrhs, and similar slight affections of the respiratory system all of which are almost epidemically prevalent, should exercise more care to prevent the development of tonsillitis, consumption, and pneumonia."

Dr. F. Fischer describes his experiments concern-

ing fatty degeneration in the Orvosok Lapja.

His experiments prove that fatty degeneration is not caused by an actual conversion of cellular protoplasm into a fat, but by deposit of fat from the circulation. A chemically pure soap was allowed to circulate through the kidney of a rabbit with glycerin, the animal then killed, and serial sections made of the hardened organ. The endothelial cells presented a finely granular appearance, while the tubular epithe-lium was in a condition of acute degeneration. With sudan all the granules were stained intensely, the fatty deposit being most marked in the convoluted tubules of first and second order, less so in the cells of Henle's loop. The tissues in the neighbourhood of vessels were most affected, especially where an artery and vein were present close together. The experiments are an evidence of active chemical changes in the cells as the soap was first split up and the fatty acids then combined with the glycerin to form which took the place of the altered cellular protoplasm.

EXTENSION OF THE POLYCLINIC HOSPITAL.

The annual meeting of the Polyclinic doctors held February 11th was signalised by the opening of new wards and private rooms, these being part of the extensive improvements made during the past eight months. The work of the Polyclinic is increasing that the clinics last very averaging to come delivered. months. The work of the Polyclinic is increasing yearly, the clinics last year averaging 103 cases daily, and 1,080 persons were admitted to the wards. In and 1,000 persons were admitted to the wards. In the accident wards over 3,000 cases were received. Three adjoining properties are owned by the Polyclinic Corporation, and on these an addition to the hospital will be erected as soon as £8,000 can be raised.

#### FROM OUR SPECIAL CORRESPONDENTS AT HOME.

#### - SCOTLAND.

EDINBURGH ROYAL ASYLUM.-Dr. G. M. Robertson submitted his first annual report on the working of the institution to the meeting of the Corporation on February 22nd. The average number of patients resident was 733; 356 men and 377 women. During the last three years the admission rate has been falling off steadily owing to the opening of Bangour Asylum, and the admissions last year numbered 237, or 78 less than in the previous year. He dwelt on the advantage taken

of the accommodation at West House, where patients are admitted at a standard rate of £45 a year; on this department there is a loss of £3 per head owing to the generous way in which the managers provide comfortable quarters for the afflicted members of the middle class who possess only moderate means. The opening of Bangour Asylum has set free adequate space in West House for this class of patient. With regard to the character of the cases admitted, Dr. Robertson stated that 26 persons were diagnosed as alcoholic insanity, a percentage of 10.8, which compared favourably with the proportion of alcoholics in previous years. A more remarkable feature was that 11 persons were admitted suffering from post-influenzal insanity, being nearly 5 per cent. of the total admissions. The poison of the influenza germ had the most injurious effects on the brain and nervous system. As a rule, these effects were not immediate, as the poison acted by slowly impairing the nutrition of the nerve cells, and after the patient had been out of sorts for a fortnight, a month, or even more, the mechanism of some nervous function or another broke down. These nervous after-effects were legion, but fortunately only a few were permanent. The extent of the mental, physical, and material damage, indirect as well as direct, sustained by the nation as a result of influenza could only be realised by comparing it with that produced by excessive indulgence in alcohol. For one case sent to the asylum scores were incapacitated. The ill-health of these was a source of misery to themselves, and, if they were bread-winners, the diminution in their earnings was followed by as serious consequences for their families as would have been the case had the head of the family been a drunkard. An epidemic of cholera would have been less of a scourge to the country than these recurrent outbreaks of influenza. The percentage of recoveries was 31.3, which was the average for the asylum since 1900. Its lowness, as compared with the early years of the asylum's history, was due to the accumulation of senile patients, and to the small number of alcoholic cases (which recovered quickly). The total death-rate was absolutely and relatively low—6.5 per cent, of the total number under treatment. Dealing with changes in the establishment, Dr. Robertson paid a tribute to Dr. Clouston's superintendentship, and said that in Craig House Dr. Clouston had a worthy and appropriate memorial. Instead of having, as in the past, a matron on the ladies' side and a head attendant on the gentlemen's side, each performing similar duties and dividing the responsibilities for the nursing and domestic arrangements, a lady superintendent has been appointed in sole charge. It is no longer necessary, for safety's sake, as in the past, to restrict the care of male patients to men. The ladies' hospital at Craig House has been enlarged, and alterations have been made which will facilitate the use of open-air treat-

REGISTRATION OF NURSES IN SCOTLAND. — An influentially-attended meeting was held in Glasgow on February 27th, Lord Monclyde in the chair, in support of the movement for the establishment of a Registration Council in Scotland, separate from England. The Chairman said the meeting had been called in response to a circular from those who had drafted a Bill applicable to Scotland, in order to get a general expression of opinion on the matter. After careful perusal of the Draft Bill it seemed to him that it would be a retrograde step to hand over to a London Council the entire control of the training of Scottish nurses. The standard of the large Scottish training schools was very high, and there was no reason why it should be interfered with. The financial requirements of the English Bill would bear hardly on Scottish nurses. Dr. Mackintosh, Medical Superintendent of the Western Infirmary, gave the result of the plebiscile of Scottish nurses in favour of the establishment of a separate Registration Council in Scotland as follows:—Matrons and superintendents, 114; assistant matrons, 57; sisters, 218; charge nurses, 163; nurses in general hospitals 736; private nurses, 446; private nurses trained in special

hospitals, 35; total, 2,718. Miss Gill, Edinburgh, spoke against the London scheme, one of the objections being that Scotland was quite inadequately represented on the Board. Dr. Oswald, on behalf of mental nurses, said that of 22 medical superintendents, representing between 1,600 and 1,800 nurses, 18 were unreservedly in favour of a Scottish system of registration. The proposal was also supported by delegates representing general hospitals, Poor-law hospitals, provincial hospitals, asylums, fever hospitals, and the medical profession. Dr. Morton, Shelleston, favoured registration by a central body for the United Kingdom, and moved an amendment, but received only 7 votes. A committee was formed to carry on the movement for a separate Scottish Registration Council.

#### BELFAST

SEWAGE PURIFICATION.—The problem of the Belfast sewage and its disposal is still unsolved despite the expenditure of about £60,000 on various experimental works during the last ten or fifteen years. The latest experiments, which are only beginning, promise to be of great interest. They consist in the construction of of great interest. They consist in the construction of a series of Dibden slate beds, and last week Mr. Lionel Dibden, son of Mr. W. J. Dibden, the inventor of the system, came to Belfast and explained the working of the process at the beds, which are almost ready for use. The beds are formed of numerous ready for use. The beds are formed of numerous shelves of slate, one over the other, with spaces between, so as to give a large superficial area of slate for the sewage to come in contact with. The crude sewage is run into the beds and allowed to remain in contact with the slates for two hours, then run off. The slate beds take about two months to mature, and when mature apparently continue active an indefinite The maturing consists in the formation of a deposit of humus on the slates, containing bacteria deposit of humus on the states, containing bacteria and small worms, and by their action the crude sewage is purified quickly and without any objectionable odour. The beds are costly, as about 9,000 cubic yards of slate bed, containing 3,000 tons of slate, and costing £6,000, exclusive of structural work, would be required for every million gallons of daily dryweather flow of sewage. But, on the other hand, there is a saving of cost as compared with the sedimentation system, in there being no sludge to dispose of. The system is a most interesting one, and has favourably impressed many of the persons who have to deal with the difficult problem in Belfast, but owing to the cost being so great the committee of the Corporation still leans to the system of sedimentation and removal of the sludge by steamer.

PUBLIC HEALTH.—At the monthly meeting of the Corporation last week, it was reported that the death-rate from all causes was 17.9, as compared with 25.8 in the same period last year. Seven cases of cerebrospinal meningitis had been notified during the month.

#### LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE CENTRAL MIDWIVES BOARD AND SEPSIS RE VAGINAL EXAMINATIONS IN MIDWIFERY DURING LABOUR.

Io the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—I am sorry to trouble you with another letter, but I desire briefly to explain that the contents of my former letter were not correctly quoted by your "Pathological" correspondent in your last week's issue. In support of his opinion he stated that the training of pupil-midwives under the rules of the Central Midwives Board will "encourage them to get into the habit of making vaginal examinations" in opposition to the best teaching of modern midwifery. Moreover, his experience leads him to doubt "whether it is possible according to my statement for a woman to gain by internal and external examinations a practical knowledge without risk to the patients." At the same time he accidentally omits any reference to the protective clause "that the practical training must

be carried on under the direct supervision of a registered medical practitioner or a certified midwife

appointed by the board for the purpose."

I feel confident that the criticism of your correspondent is the outcome of a sincere desire to promote spongent is the outcome or a sincere desire to promote aseptic treatment in every department of practice; and that he is stimulated by a profound hope—mingled with a little anxiety—that midwives will be trained to correctly carry out every precaution, and also to be ever ready to follow well defined regulations.

I am, Sir, yours truly,

JOHN WARD COUSINS.

Portsmouth, March 8th, 1909.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—"Obstetrician" says in his letter (see MED. PRESS AND CIRCULAR of February 24th, 1909, p. 197):-"To make vaginal examinations with satisfactory results, the nurse must acquire experience, and how can she do this unless she makes 'repeated vaginal examinations' during her training? It is far better she should make them then, when presumably under proper control and supervision, instead of after her training, when she is in a comparatively irresponsible position.

May I say that since I first began systematically to train ladies to be midwives and for district midwifery work in 1879, I always allowed them to sit with me while seeing the out-patients, and in this way they saw the gynæcological cases, learned the conditions in health and disease, not only of the os and cervix uteri, but of urethra and all the pudenda, of the

perinæum, rectum, etc.

From 1879 on we worked, before the L.O.S.—and subsequently the C.M.B.—came into existence, and our Board of Examiners testified to the excellent theoretical and practical efficiency of the students—a testimony amply corroborated by the splendid work done abroad in all those Eastern Countries where women only are allowed to see the women and their children, and minister to them medically. This plan we adopted at the very first, and carry on up to this day, and many of our students are skilled in use of catheter, speculum, etc., as well as in the use of midwifery instruments of different kinds. I had got so far when a lady missionary, on furlough from India, called on me to know if she might come to sit with me, and thus see some of our gynæcological practice, as it would be of such immense service on her return to her sphere of labour. She came because she had heard from some of our former ladies, trained in the first days of the Zenana Medical Mission College, and she bore good tidings of the work they were enabled to do in both gyngecological and midwifery cases. In the latter branch they now have so many calls they can only attend the difficult and operative cases, but, as they have trained some native women, our pupils are relieved by them from attendance upon all ordinary labours. Such an account, coming from students of those far-off days (for at first the natives would not have them at all till they had seen and heard of the good they had done in non-midwifery cases) is most encouraging.

I am, Sir, yours truly, G. DE G. GRIFFITH. London.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—I do not know how to set about convincing "Pathological" of the necessity of teaching midwives both how to make vaginal examinations and how to obtain information from them, and if I try to do so I am afraid I shall repeat myself. However I will

try.

There are a number of points of vital importance which can only be learnt during labour by means of a vaginal examination, such for instance as prolapse of the cord, tumours of the bony pelvis or of the

appendages and fœtal monstrosities.

None of these things can be appreciated by the midwife unless she has gained a clear knowledge of the results of vaginal examination in the case of normal labour.

To gain this knowledge she must have made a number of vaginal examinations.

Vaginal examinations can not be made absolutely safe, but they can be made relatively safe by careful instruction, not alone in the nature of the danger but in the technique of the examination.

As soon as a midwife has acquired practical skill in the making of vaginal examinations the fewer she makes the better. While she is in statu pupillari, the few patients on whom she makes the examination have to suffer for the benefit of the many. Is it not always

so in the teaching of medicine?

Vaginal examinations are harmful, but they are vaginal examinations with the said of midwives. Both have been introduced to combat a greater evil, and this being so the best we can do with them is to render them as innocuous as possible, and to increase the service they render to the maximum.

The whole point is so obvious to me that I find a difficulty in understanding "Pathological's" point of view. Perhaps it would simplify matters if he will tell us what he advises under the circumstances, and not what he condemns.

I am, Sir, yours truly, OBSTETRICIAN.

#### OXYGEN IN SPORT.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In his reply to my letter on "Oxygen in Sport," Dr. Leonard Hill is confusing the point at issue. He Dr. Leonard Hill is confusing the point at issue. He alludes to the use of oxygen twenty-five years ago by W. G. George, and refers to his own work in the Journal of Physiology. If Dr. Hill's researches were made before 1892 I ought, of course, when I wrote, to have known of them. If not, it is evident that I had previously demonstrated the fall of tension under torced avarges and its recovery by oxygen in the forced exercise, and its recovery by oxygen in the systemic arteries, and consequently in the left ventricle The sphygmograph may not be, as Dr. Hill remarks, an exact measurer of tension of the left heart, but it indicates its variations.

Dr. Hill to prove his case misquotes me as follows: "It (oxygen) does not restore wind at once by rendering the lung adequate to the extraordinary demand upon it." He goes on to say, "what I have ascertained is that oxygen inhalation affords a simple and powerful method of relieving the fatigue of the heart which follows extreme muscular effort, and that which follows extreme muscular effort, and that oxygen and exercise can be used as a valuable method of treatment." If Dr. Hill, who considers that my explanation of the action of oxygen is "wholly wrong," will kindly take the trouble to re-read my letter he will find that I gave long ago the same (the only possible) explanation as himself—the reverse of what he quotes me as saying. I demonstrated what he has since ascertained, that oxygen in restoring wind

what he quotes me as saying. I demonstrated what he has since ascertained, that oxygen in restoring wind did it by restoring the adequacy of the lung.

As regards oxygen and exercise (used simultaneously) being a valuable method of treatment, again Dr. Hill has discovered a plan pointed out by me at the time, and which I have frequently used in diseases of decreased oxidation, and also in the heart flag of morphinism due partly to the same cause. My modus operandi has been to associate the inhalation of oxygen with exercise on a home trainer, and I have often found it useful in these cases. In order, moreover, to protect myself from the accusation of copying future inventors I added in 1802, when I recommended this plan for gout and for other results of insufficient combustion, the following note to my article on "Oxygen in Sport": "Les inhalations d'oxygène ou d'ozone associées à l'exercice approprié, soit actif, soit passif, j'ose l'affirmer, deviendront le traitement par excellence Jose l'amrmer, deviendront le traitement par excellence de la goutte et de toutes les maladies à combustion insuffisante. Mais je ne fais que mentionner cette application ici pour prendre date et pour empêcher qu'on m'emprunte l'idée première de cette méthode."

I am, Sir, yours truly,

OSCAR JENNINGS, M.D. (Paris).

#### THE NAVY AND PROPHYLAXIS AGAINST SYPHILIS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your issue of March 3rd you refer to a question I asked the First Lord of the Admiralty, and his reply. This was with reference to the proposed syphilisation of all the men in the Navy as a precaution against syphilitic disease, and you say at the conclusion: "Any honest effort, however mistaken, to

onclusion: "Any nonest enort, nowever inistates, to prevent the gigantic evil, is deserving at least of respectful consideration."

With regard to that, I would say that there are perhaps different ways of showing "respectful consideration." One shows respect for a foe by shooting him; one shows respect for the devil by hating him and all his works. And that is the only way in which I could impairs any competent and thoughtful which I could imagine any competent and thoughtful statesman regarding the suggestion of Dr. Munimery. Surely, apart from the medical aspects of the case. every man who had to undergo the operation would be degraded. Surely the surgeons and doctors of the world have some character to maintain, and derive some advantage from the esteem of their fellow-creatures, which should not be lightly risked by pro-

Positions of this kind!

But to refer to the medical aspect of the case. Suppose, for the sake of argument, that the proposed operation did reduce the liability to contract the disease in a worse form, what evidence is there, what evidence could be obtained in a less time than thirty years, that the insertion of syphilitic pus from an anthropoid ape would not do far more harm than it did good? But the assumption that the process would have the desired effect is surely too large a one for have the desired effect is surely too large a one for any person accustomed to examine evidence to give it a "respectful consideration." Does the acquisition of the disease once render the diseased person free from any further attack of the disease? Is there any surgeon of experience prepared to answer that question in the affirmative? Does not Dr. Mummery's own paper contain ample evidence that the process which he suggests is quite unnecessary, and that any man of ordinary prudence and good conduct has nothing to fear from the hideous disease referred to, except it is from the lancet, poisoned in the manner that he would recommend?

I am, Sir, yours truly, ARNOLD LUPTON.

March 6th, 1909.

#### PAYING PATIENTS IN CHARITABLE HOSPITALS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR SIR,—I should be obliged if you could spare me space for the explanation of one point in your leading article "Private Patients in Charitable Hospitals."

You state that the Chairman "read from a circular ent to every applicant for attendance in the private

From this account your readers will form the opinion as did everybody present at the hospital meeting, and all those who read the accounts in the newspapers) that these circulars and regulations had existed to control abuse, whereas the fact was that no regula-tions whatever had existed, and no "circulars" either, until shortly before the meeting, and the week before the meeting they had not even been printed!

I did not know this at the time of the meeting, but when I learnt the fact, I addressed the two following questions to the Chairman, through the columns of the Liverpool Daily Post and Mercury:—

"(1) Is it a fact that the form and regulations which he read to the meeting had no existence before the last meeting of the Committee previous to the annual meeting; that these regulations were accepted and passed by the Committee at that meeting in view of the annual meeting; and that they were so recent that it would have been impossible two weeks ago to procure a copy in print?

"(2) Is it a fact that, previous to the adoption (less than one month ago, and after my recent correspondence, and in view of the annual meeting) of this specific form he read out, no such series of question or form for signature of any kind existed?"

The Secretary-Superintendent of the hospital was instructed to answer these questions, and—rather comically—while denying their truth, he stated that these regulations had been adopted on January 4thfive weeks to the day before the annual meeting.

Six months ago I had some private correspondence with the Chairman, and then informed him I should protest at the annual meeting. On November 28th and December 1st I had letters in the Post. During December the Medical Board drew up regulations for recommendation to the Committee, and at the meeting of the Committee on January 4th this form for private patients was accepted, but a recommendation made at the same time by the Medical Board that "the Medical Officer should be at liberty to charge fees for attendance upon occupants of the private wards" was rejected, the voting being 8 against, 4 not voting, and 1 in favour, and this one was the only member of the medical staff present!

.Considering the autocratic and offensive manner in which this same subject has been treated on several occasions previously by this Committee, I am pleased to have forced them to grant a small, though painful. concession to justice, and I trust that in some way sufficient pressure may be brought to bear to bring

them to their senses.

Private wards in charitable hospitals are essentially wrong, both to the charitable funds and the medical profession. They must be swept away. But, in the meantime, chairmen and committees such as exist at the Liverpool Southern Hospital must be compelled to abstain from working them so as to inflict the maximum possible injustice upon the medical profession. The recent discussion in the Liverpool press has done much to educate public opinion, and I am pleased to find that it has awakened a great expression of acknowledgment of the present injustice. I trust that the profession at large, and the medical press, will not allow the subject to drop, but help in every possible way to force an early reconsideration and readjustment of the relationship of the medical profession to medical relief.

I am, Sir, yours truly, CHARLES W. HAYWARD.

Liverpool.

THE NEWSPAPER PRESS AND QUACKERY. To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—My personal thanks are due to Dr. Oscar Jennings for his valuable letter published in your last issue. I have not a word of criticism to pass upon it—it is true and admirable throughout. I wish merely to make plain some of my views with regard to the proposed Royal Commission. But first I would like in parenthesis to point out that neither the like, in parenthesis, to point out that neither the General Medical Council, nor the Council of the British Medical Association has included the question of quack medicines in its proposals for a Commission. If this question be left out in any inquiry into the subject it will prove practically useless. Fraudulent quacks, finding the dodge by far the safest, are more and more carrying on practice under the cloak of the sale of nostrums and apparatus. They do not directly adopt medical titles, but employ fictitious doctors' names in their advertisements, and use language leading the simple public to believe that when in the hands of the quacks they are consulting duly qualified practitioners.

I look upon a Royal Commission as merely a means towards certain ends, not as an end in itself. In the first place, it would bring shame to newspaper proprietors, and force some of them to mend their ways. The number of papers that make any effort to cleanse their pages from fraudulent quack advertisements is rapidly diminishing. I allude not only to London, but provincial papers. Many of the latter are not inferior in any way to their London contemporaries. The cynical impudence of some of them is amazing. Within late years great papers in London and the country have published leading articles condemning systems of quackery exposed in the courts, whilst themselves publishing costly puffs of these same frauds. One paper had a powerful leader pointing out the harm done by sham tonics containing alcohol, and urging that their sale should be prohibited by law. and on the same page printed a costly puff of one of the most advertised of these pernicious preparations. Another great paper published an article which

was, in fact, a brief summary of my address delivered before branches of the British Medical Association two years ago. The article spoke of the quack drug trade as constituting a grave national danger, and, in almost the same words as I had used, exemplified and illustrated the fact by reference to the injurious and deadly results of self-drugging by simple, suffering people. I have made a careful estimate of the income derived by the owners of this paper from advertisements it denounces as fraudulent and cruel, and have satisfied myself that it does not amount to less than £50,000 a year. If a Royal Commission were appointed the owners, these censors of public and private morality could be called as witnesses and asked to justify their conduct. The vendors of nostrums and apparatus would also be called and examined, and confronted with the promises in their advertisements; with the analyses and dissections of their wares, and with exposure of the actual cost of these. There would be unfolded an astonishing tale of cynical villainy on the one hand and of popular credulity on the other. It would force the attention of statesmen to the subject, and means would be found to put an end to the worst of the evils. The Food and Drugs Acts, and the Merchandise Marks Acts serve to check and prevent abuses much less serious; and I have previously shown that amendment of the laws dealing with the offence of obtaining money under false pretences, together with reform of the Medical Acts, would certainly put an end speedily to many of the existing evils. Some philanthropic, patriotic, and public-spirited newspaper proprietors would, under such new laws, probably find themselves in the dock along with the criminals whose profits they are now sharing.

I am, Sir, yours truly, HENRY SEWILL.

March 3rd, 1909.

#### **OBITUARY.**

MR. THOMAS WAKLEY (Editor of *The Lancet*). WE announce with much regret the death of Mr. Thomas Wakley, which took place on Friday last at 16 Hyde Park Gate, London, S.W., at the age of 57. Mr. Wakley, who was born in London in 1851, was the only son of the late Thomas H. Wakley, F.R.C.S., and grandson of the late Mr. Thomas Wakley, M.P., Coroner, who was the founder of *The Lancet*. He was educated at Westminster, Trinity College, Cambridge, and St. Thomas's Hospital, and became a Licentiate of the Royal College of Physicians in 1883. He married Gladys Muriel, eldest daughter of the late Mr. Norman Barron, and has one son, between four and five years of age. He was a Fellow of the Royal Numismatic Society.

Mr. Wakley was best known as Editor of The Lancet, to the joint editorship of which he succeeded in 1887. Socially he was a particularly shy and retiring man, who accepted the responsibility of his position, but in every way avoided public appearance. He was, however, a keen Freemason, and at one time held Grand Office in that Order. His death breaks the editorial succession of a journal the history of which marks one of the brilliant opening stages of medical journalism in the United Kingdom, of which it may truthfully be said that it has become the pattern and exemplar of that and similar literature throughout the civilised world.

The funeral service took place to-day at St. Mary Abbot's, Kensington, and at Putney Vale Cemetery.

PETER HORROCKS, M.B.Lond., F.R.C.P., M.R.C.S. WE regret to announce the death, on February 28th, after an operation, of Dr. Peter Horrocks, Senior Obstetric Physician to Guy's Hospital, at the age of 56. Dr. Horrocks was a Fellow of the Royal College of Physicians and a member of the Royal College of Surgeons. He obtained his M.B. degree of the University of London in 1877, and was awarded a gold medal. He was educated at Guy's Hospital and Owens College, Manchester. At the time of his death

he was Senior Obstetric Physician at Guy's and Lecturer on Obstetrics at the hospital medical school. He was an Examiner in Medicine at the Universities of London, Leeds, and Liverpool, and was also an Examiner on the Conjoint Board of the Royal Colleges of Physicians and Surgeons of London. In 1894 Dr. Horrocks had a narrow escape while Alpine climbing. On returning home he opened a subscription list for the widow and seven children of the guide who lost his life.

DR. JOHN AMBROSE, R.A.M.C.
The sudden death is announced of Dr. John Ambrose, retired Lieut.-Colonel of the Royal Army Medical Corps, who was found dead in his diningroom at Southgate Lodge on Saturday evening. The deceased, who was in his 68th year, had been in his usual state of health. He had dined alone on Saturday evening, and shortly afterwards, when the servant went in to clear the table, she found her master on the floor, partly under the table, dead. The deceased had not been medically attended, but some two years ago he consulted a London specialist in respect of severe headaches. He appeared, however, to be quite cured of these. The deceased officer had been resident at Devizes for a quarter of a century, and was for the greater portion of that time Medical Officer in charge of the station hospital at Devizes Barracks (Wilts Regimental Depôt). He was very popular, and his death is greatly regretted.

#### REVIEWS OF BOOKS.

INTERNATIONAL CLINICS. (a) This is a good clinical number of this popular quarterly journal. In the section devoted to therapeutics, two novelties are discussed. These are the treatment of pertussis by fluoroform, and the treatment of tetanus by cholesterin. Tissier contributes the former paper, and speaks strongly of the value of a watery solution of fluoroform in allaying the symptoms and abbreviating the course of whooping-cough. Further independent testimony is, however, required before one can place undue reliance on his results. The paper on tetanus is written in a modest style by two Italians, Almagia and Mendes. Their treatment is based on their observations on the fixing power exerted by cholesterin and lecithin on tetano-toxin, but their results, as they admit themselves, are suggestive rather than convincing. Sherrens' paper on the diagnosis of injuries of the peripheral nerves from those of the spinal cord is a valuable contribution to the subject, and deserves careful study. Any careful investigator must be aware of the fact that the differential diagnosis of traumatic nerve and cord lesions is often a matter of extreme difficulty, and to such investigators the paper will appeal. Four other papers on nervous and psychical diseases are included in the present volume, the most interesting of them being one by Jastrow entitled "On the Trail of the Sub-conscious." Admirers of Meyers' "Human Personality" will receive this paper with interest, and will find within it some striking records of double consciousness. The section on surgery contains papers on "Melanotic Neoplasms," on "Adenomata of the Thyroid Gland," on "Pericolic Inflammations," and on "The Treatment of Fractures by Direct Internal Splintage." An interesting early case of myositis ossificans is recorded by Dr. Jeliffe, and an account of some cases of leukæmic retinitis is given under the section devoted to ophthalmology by Duvigneaud. The volume, as usual, is well got up, is well illustrated, and is altogether presented in a most attractive style.

INFECTIOUS AND PARASITIC DISEASES. (b)
This manual is intended for the use of medical students and nurses more especially, but at the same

<sup>(</sup>a) "International Clinics." Vol. III. Eighteenth Series. Philadeiphia and London: J. B. Lippincott Co. 1908.

(b) "Introduction to Infectious and Parasitic Diseases." By Millard Langdeld, A.B., M.B., Professor of Bacteriology and Clinical Medicine, John Creighton Medical College, Omaha. London: Rebman, Ltd. 1908. Price 5s. 6d. net.

time it is hoped that medical men will profit by its perusal. We have read it from cover to cover, and feel bound to admit that there is no better introduction to the study of bacteria and bacterial infections. The elementary style in which the book is written makes its study extremely easy to the uninitiated, provided they possess a rudimentary knowledge of medicine. Passing from a consideration of the causes of disease, the author takes his reader in rapid succession through the main principles of bacteriology, the phenomena of infection, animal parasites, and the portals of entry and exit of the various infectious agents and parasites. There is also a chapter on disinfection and disinfectants. The mode of collecting and examining secretions and excretions is likewise briefly referred to.

We notice that the author is of opinion that "very few vaginal discharges in children" are due to any are due to any tion. This is a other cause save gonorrhoeal infection. matter of opinion, with which we are unable to agree. There are surely many other causes, equally frequent, such as measles, threadworms, and the like. The volume has a commendatory note by Professor Barker, of Baltimore, but it stands in no need of any such recommendation; and we feel convinced that no student or general practitioner will regret studying it, as its perusal will certainly give him an insight into the principles of the origin of such diseases as are referred to, and a first knowledge to which he may the more readily add by wider reading. The volume, moreover, is so well printed and so neatly bound that it becomes a veritable pleasure to read and to handle it.

ESSENTIALS OF DIETETICS. (a)

THE object with which this work was compiled was the instruction of nurses in practical dietetics, and assuredly this is a highly important, nay, indispensable branch of their training. Incidentally, of course, it will be appreciated by women who, without any technical training, have to nurse at home, that is to say, the general public.

We can cordially recommend the book, which is admirably written in plain English, and contains just such information, theoretical and practical, as is required by the readers for whose benefit it was written. We are told how to distinguish good food from bad, the various ways of preparing it, and the conditions in which it may be given, together with the abnormal states in which it is to be withheld. There are close on a hundred pages of miscellaneous information and recipes for invalid dishes, with directions for their preparation. For all practical purposes it will be found a useful work of reference even by medical men with whom, as a rule, practical dietetics is not a strong point.

#### Medical News in Brief.

#### The Annual Meeting of the National Hospital for Consumption, Ireland

THE annual meeting of this hospital was held on March 3rd. Her Excellency the Countess of Aberdeen was present. The Chairman, Mr. O'Brien Furlong, C.B., in moving the adoption of the report, said that there were 480 patients treated in the year-22 more than in the previous year; 380 had been discharged, and 10 had died. The average stay of patients in the hospital was 12 weeks. The great bulk of those admitted—268 being men and 212 women—were between the ages of 16 and 40 years; but the highest percentage in the age period was between 21 and 25 years in all groups. Patients were classified in four groups, according to the stage of the disease, and this showed in a striking way the importance of early treatment. The first group contains the patients with early and limited disease—that was, in the incipient stage of consumption; out of 177 cases, 163 were "improved," and of these 57, or 32 per cent., were

(a) "Essentials of Dietotics in Health and Disease." By Amy Elizabeth Pope and Mary L. Carpenter. London: G. P. Patmans'

"very much improved "-that was to say. the disease was apparently arrested and health restored. figures were, he thought, sufficient justification for the existence of that hospital. Where the disease was of long standing, out of 84 cases 31 "improved," and none "very much." That went to show that as a curative agency the sanatorium availed little to restore health,

unless the disease was arrested in its early stages.

Amongst the subsequent speakers were Lady Aberdeen, the President of the Royal College of Physicians, and Sir M. J. Thompson.

Annual Report of the City of Lenden Cere In his annual return to the Home Office, Dr. F. J. Waldo, Coroner for the City of London and Southwark, states that in the year ended December 31st last he held 418 inquests, including non-fatal fire inquests. It was to be noted that 37 fatal accidents were due to vehicles, of which 9 in the City and 13 in Southwark were drawn by horses, and 12 in the City and 3 in Southwark were motor drawn. There was an increase of cases of "suicide," and a decrease of cases of "children suffocated whilst in bed with their parents or others." Of 9 deaths attributable to "neglect, exposure, or excess," only 5 (2 males and 3 females) were found by the jury to be directly due to disease caused by excessive drinking. The Coroner points out that a tentative measure in the shape of a proposed general Appethetics Bill is now under the consideration. general Anæsthetics Bill is now under the consideration of the Privy Council and Home Office, which Bill limits the administration of anæsthetics to registered medical practitioners, and requires that all candidates, before presenting themselves for their final medical examination, shall have received thorough theoretical and practical instruction in anæsthetics, under the supervision and to the complete satisfaction of their respective teachers. He adds that present available data as to deaths during anæsthesia are so imperfect as to be useless for the purpose of formal investigation, and that it is highly desirable to arrive at satisfactory conclusions regarding all deaths under anæsthesia, both for the safety of the public and for the furtherance of scientific knowledge.

The Prujential Assurance Company.

The annual report for the year ending December, 1908, of this well-known Society has reached us in due course. Needless to say, it registers once more that steady increase of prosperity which is synonymous with the name of this well-managed corporation. The directors draw special attention to the fact of a substantial increase in the industrial branch bonus. The total number of policies in force at the end of the year reached the astounding figure of 17,963,127.
There is no more interesting chapter in the history of insurance in the United Kingdom than that which records the rise and progress of the Prudential Assurance Company.

Women Sanitary Inspectors in the City of London.

A MEETING of the Corporation was held recently in the Guildhall, the Lord Mayor presiding. On a report by the Sanitary Committee increasing the salaries of the women sanitary inspectors to £200 each and regulating the appointment of a fresh woman inspector, Sir Robert Rogers said that women inspectors in the City were an abomination and a nuisance. There was no official duty done by a woman which could not be better done by a man. Mr. Link said that the work of the women inspectors had greatly increased in volume and importance of late years, and other authorities outside the City were paying even higher salaries than were suggested. Mr. H. P. Monckton said that the women inspectors worked in some 20 different useful directions; their salaries were about 25 per cent. less than those of men discharging similar duties. The report was eventually carried.

Trinity College, Dublia.

THE following candidates passed the Final Examination in Medicine, Part I., Hilary Term, 1909:—John H. Woodroffe, Marius A. Diemont, and Hilgard Müller (passed on high marks); Arnold K. Henry, Arthur C. Hallowes, Beatrice M. Hamilton, Charles H. Denham and Richard H. Mathews (æq.), Perceval G. Leeman, John W. Flood, John B. Burgess.

#### NOTICES TO CORRESPONDENTS, &c.

Correspondents requiring a reply in this column are particularly requested to make use of a Distinctive Signature or Initial, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

BUBSCRIPTIONS.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home cr abroad. Foreign subscriptions must be paid in advance. For India, Messrs Thacker, Spink and Co., of Calcutta, are our officially appointed agents. Indian subscriptions are Rs 15.12. Messrs. Dawson and Sons are our special agents for Canada.

#### ADVERTICEMENTS.

ADVERTISMENTs.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2:10s.; Quarter Page, £15s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3:10s.; 26 at £3:3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion, 6d. per line beyond.

FACTORY SURGEON (Hford).—Should a person decline operation through fear of taking chloroform or other annesthetic, the responsibility rests upon himself. The question has been raised in workmen's compensation cases whether the refusal of operation, where the latter is essential to the cure of some defect arising out of the causative accident, should not invalidate the claim for permanent compensation. A recent case in Manchester appears to show that the claimant would under such circumstances place himself out of court. In that particular instance the claimant agreed to be operated upon after hearing the judge's views.

indge's views.

K. G. H. (Cricklewood),—The person you mention is an unqualified person with a West-End establishment. He professes to cure various diseases by massage and physical exercises. Under the circumstances, we should advise your patient to consult a solicitor as to the best course to pursue

SANITARY INSPECTOR.—The next meeting of the National Federation of Meat Traders' Association will be held at Blackpool. Their policy is to place the responsibility of warranty upon the vendors of stock. Their solution seems sound enough. In any case, the natter should be settled, for the safety of the public is closely associated with its speedy solution.

Surgeon to the Boscombe and West Hants Hospital.

SMITH FRANCIS R., M.R.C.S., L.R.C.P.Lond. L.D.S., Surgeon
to the Victoria Hospital for Children, Chelsea.

#### Vacancies.

Brixton Dispensary, Water Lane, S.W.—Resident Medical Officer. Salary, £150 per annum, with furnished apartments, attendance, coal and gas. Applications to W. Halliday, Secrets, y. West London Hospital, Hammersmith Road, W.—Pathologist, Salary, £200 per annum. Applications to R. J. Gilbert, Secretary-Superintendent.

London County Asylum, Horton, Epsom, Surrey.—Junior Assistant Medical Officer. Salary, £160 a year, with board turnished apartments, and washing. Applications to H. F. Keene, Clerk of the Asylums Committee, Asylums Committee Office, 6, Waterloo Place, London S.W.

York Dispensary.—Resident Medical Officer. Salary £150 a year, with board, lodging, and attendance. Applications to Dr. Swanson. The Pleasaunce, Heworth, York.

Gateshad Dispensary.—Assistant Medical Officer. Salary, £180 per annum, without board or lodging Applications to W. Swinburne, Hon, Sec., Town Hall, Gateshead-on-Tyne.

County Asylum, Mickleover, Derby.—Junior Assistant Medical Officer. Salary £120 per annum, with furnished apartments, board, washing, and attendance. Applications to the Medical Superintendent.

Longford Union.—Medical Officer. Salary, £120 per annum. together with the usual vaccination and registration fees.

glord Union.—Medical Officer. Salary, £120 per annum. together with the usual vaccination and registration fees. Applications to J. F. M'Cann, Clerk of the Union. (See advt.)

#### Births.

GIBSON.—On March 7th, at 46, St. Giles Oxford the wife of Alexander Gibson, M.D. of a son.

HARLSER, -On March 4th, at Tynemouth, the wife of W. Edmund Harlser, M.D.D., D.H.y., of a son.

HICHENS.—On March 2nd, at Northampton, the wife of Peverell S. Hichens, M.D., M.R.C.P. of a son.

OWEN.TATIOR.—On March 7th, at Cherwell House, Nottingham, the wife of Herbert Owen.Taylor, Esq., M.D., of a son.

#### Beaths.

BINNING.—On March 4th, at Hatfield, Herts, the wife of Alexander Binning, M.D., aged 29.

WarLer.—On March 5th, at 16 Hyde Park Gate, London, Thomas Wakley, L.R.C.P.Lond., only son of the late Thomas Henry Wakley, F.R.C.S.Eng., and grandson of the late Thomas Wakley, M.P., aged fifty-seven years.

## Influenza and its Sequelæ.

The antiseptic, soothing and tonic properties of Angier's Emulsion eminently adapt it to the treatment of the catarrhal symptoms, whether tonsillar, bronchial or intestinal, which so generally follow the more acute stage of Influenza. It is most efficacious in relieving the troublesome laryngeal, or tracheal cough, while it also allays the dangerous symptoms of congestion and inflammation of the respiratory organs and obviates the tendency to pneumonia and pleurisy. "Moreover, the hypophosphites in the Emulsion combat the nervous depression and tone up the nervous system generally. After a serious attack of Influenza when the patient's nutrition and vitality are at the lowest ebb try the continued use of Angier's Emulsion for a convincing proof of its effects as a tonic and reconstructive.

## ANGIER'S EMULSION

(Petroleum with Hypophosphites.)

#### Debility After Influenza.

Liverpool, Feb. 17th, 1909.

Dear Sirs,—I have prescribed Angier's Emulsion for about sixteen years and have found it a valuable help in many cases of debility a'ter influenza, pneumonia, pleurisy and bronchitis. I have also had good results from its use in intestinal trouble in children. It is palatable and can be taken when codliver oil causes nausea.

(Signed) —, L.R.C.P., L.R.C.S., &c.

### Cough Following Influenza.

Dear Sira,—I have used Angier's Emulsion in a number of chest cases, notably in cough following influenza and in the later stages of bronchitis in children, and have never known it to fail. In one case of advanced phthisis it gave a good deal of relief. After trial in a multitude of chest cases, I consider it far superior to all other emulsions.

# LISTERINE

## The standard American antiseptic for internal and external use

Awarded Gold Medal (Highest Award) Lewis & Clark Centennial Exposition, Portland, 1905; Awarded Gold Medal (Highest Award) Louisiana Purchase Exposition, St. Louis, 1904; Awarded Bronze Medal (Highest Award), Exposition Universelle de 1900, Paris.

The word Listerine assures to the Medical Profession a non-poisonous antiseptic of well proven efficacy; uniform and definite in preparation, and having a wide field of usefulness.

Listerine represents the maximum of antiseptic strength in the relation that it is the least harmful to the human organism in the quantity required to produce the desired result; as such, it is generally accepted as the standard antiseptic preparation for general use, especially for those purposes where a poisonous or corrosive disinfectant can not be used with safety. It has won the confidence of medical men by reason of the standard of excellence (both as regards antiseptic strength and pharmaceutical elegance), which has been so strictly observed in its manufacture during the many years it has been at their command.

The success of Listerine is based upon merit, i.e., the best advertisement of Listerine is Listerine.

# LAMBERT PHARMACAL COMPANY,

ST. LOUIS, U.S.A.

In combating serious illness, it is doubly important to be assured that the patient is supplied with genuine Listerine, as the substitutes sometimes offered by the trade are generally of undetermined antiseptic strength, and too often worthless for the purposes for which they are required.

### Notes and Comments.

A CORRESPONDENT has drawn atten-Continental tion to a matter that deserves Hotel comment in the interests of our Dectors. travelling countrymen. He refers to the medical men attached to many of the hotels on the Continent, and to the fees charged to visitors who may require their services. In one specific instance quoted by him, a lady of narrow means happened to be stopping in a wellknown hotel in Switzerland, and called in the "hotel doctor" for advice as to a slight sore throat. The attack was controlled by a simple gargle, but several visits were made, and an account sent in eventually at the rate of £2 2s. a visit. The matter is rendered more serious by the statement that the medical man in question was a shareholder in the hotel. The lady might have secured the services of a competent outside practitioner at a fee of ten francs a visit. All who are well acquainted with the Continent know of cases of the kind, and it is a fact that sometimes the favoured medical man is a relative of the proprietor. From our own knowledge we can supplement the experience of our correspondent by that of a young lady who had a slight attack of faintness in a Riviera health resort. The hotel doctor was summoned, and the parents had to pay an exorbitant sum for an absolutely trivial and fleeting ailment.

What is to be Done?

CLEARLY if this sort of thing continues a great deal of harm will be done to Continental hotels. Visitors will fight shy of calling in medical men at all, and much mischief may

result in cases of serious illness. Yet there must be some perfectly simple way out of the wood in dealing with so honourable a profession as that of medicine. Indeed, some hotel proprietors adopt a method whereby any risk of misunderstanding is entirely prevented. Where there is nearly always an official hotel doctor, so to speak, it is clearly understood what are his fees, and at the same time a list of medical men practising in the town is available, and full information as to their fees and other special information is freely given. The travelling public necessarily comes from the monied classes, but the prices of Continental resorts have risen so enormously of recent years that the question of cost becomes more and more a matter for careful consideration. In any case, hotel proprietors will do well to see that the fees charged by medical attendants in ordinary cases are not excessive. Otherwise the feeling of dissatisfaction that has shown itself recently in not a few quarters may, in time, impair the fortunes of more than one wellknown health resort. This is a case in which the Continental hotel proprietor should emphatically be warned in time.

Small-pox at Bristol. For some time past there have been sporadic cases of small-pox at Bristol, introduced, it now appears, by a dock-labourer from the east of

Europe, and owing to faulty diagnosis and the mildness of some of the cases, the disease has become uncomfortably disseminated throughout the city. It is true there have only been twenty-three cases, but latterly they have been occurring in scattered groups at distant spots, and from collateral circumstances it is evident that a large number of persons have been exposed to infection. Dr. Davies, the medical officer of health, who has been doing his best to follow up the cases and to secure re-vaccination of contacts, has found that, owing to delay in notification and other circumstances, he has lost control of the disease, and consequently he fears an outbreak which may be of some severity. The Local Government Board consequently sent down Dr. Sweeting, one of their medical inspectors, who advises that, as a first step, facilities for vaccination and re-vaccination should be offered by the Guardians. His suggestions are that the vaccination officers should visit infected neighbourhoods and offer vaccination, that posters and bills indicating the necessity for the operation should be published, and that re-vaccination should be carried out, if need be, at workshops and factories.

Guardians as lature having conferred on the guardians the power to make arrangements for vaccination, rather than on the sanitary authority, to which

such matters would naturally be referred, it follows that the important duties of carrying out Dr. Sweeting's advice devolves upon them. Last week he attended a special meeting of the Guardians and laid the situation fully before them. Now it seems there is a strong anti-vaccinationist party of the Board, and Dr. Sweeting was not only treated with sneers by some of these gentlemen, but his advice was scouted by them. One person seems to have made himself especially obnoxious, refusing even to obey the chairman, and talked the usual clatter of his class about medical faddism, and so on. Eventually, after an animated debate, the motion to carry out Dr. Sweeting's proposal was defeated by 26 votes to 16. It remains to be seen what course will be taken by the outbreak in the first place, and the Local Government Board in the second. The latter body has power to supersede the guardians if it thinks fit, and no doubt if an epidemic threatens it will not hesitate to do so. The health authorities are doing their best, but if a widespread epidemic takes place, Bristol will only have itself to thank for having elected gentlemen of the present stamp to represent its interests.

THERE have also been two cases of small-pox at Bolton, which are said to have been infected in a rather curious way. The medical officer of health attributes the source of the

disease to the handling, by a female operative, of Egyptian cotton. Formerly there was no small-pox in Bolton, but in Egypt the disease is fairly prevalent. The medical officer of a neighbouring town considers that the method of infection consists in the habit which the women have of licking their fingers to enable them to piece together broken threads, and suggests that a moistened pad should be provided to enable them to do without the licking process. Certain it is that small-pox can be conveyed by fomites, and undoubted examples of infection by this method have occurred over and over ogain, so that it is quite likely that the Egyptian cotton may be the source of infection. On the other hand, it is by no means easy to assert that the disease can be incurred by any particular habit, and it is still more certain that to make factory operatives adopt any plan which they are unaccustomed to and which entails trouble, is a herculean Surely the simplest plan is to have all the hands re-vaccinated.

Milk Depôt Closed. The policy of establishing milk depôts for babies in large towns has always seemed to us a rather doubtful one, because it is in itself an admission that the milk is

dangerous, and consequently that somebody should be prosecuted. We cordially admit that the measure was undertaken from the best possible motives, but it has seemed as though its advocates were working at the end instead of at the begin-Certainly in some boroughs some apprening. ciable success has attended on their efforts, but in others it has not been so apparent. In Finsbury, last month, the Borough Council decided by a substantial majority to close their depôt, which has been but little patronised and has had no appreciable effect on the infantile mortality. therefore, of spending £400 or £500 in that way, they propose to appoint two health visitors at £100 a year. It is earnestly to be hoped that, busy as this session is, Mr. Burns will push forward and carry through his Milk Bill. Important, doubtless, as are the other measures before Parliament, there is hardly a single factor in the health of the nation which needs more drastic handling than the milk question, and as such it should be recognised in the Government programme, and dealt with accordingly.

#### LEADING ARTICLES.

THE CHARITY OF THE PROFESSION.—II.

The money earned by medical men in the practice of their profession is seldom, if ever, enough to enable them, after duly providing for their families, to leave any considerable sum to medical charities or other philanthropic objects. Brewing, soap manufacturing, and the distillation of spirits frequently bring to the presiding geniuses a superfluity of wealth, and such of them as give money to the charities of their neighbourhoods receive the plaudits of their fellows. The charity which a medical man can expect to receive, when laid low by illness, due to devotion to duty or to accidents of his profession, is little enough, and of reward from the

State he gets nil. Truly, to the honour of the late Prime Minister, it must be recorded that he conferred a Civil List pension on Dr. Hall Edwards, whose misfortune and suffering we all deplore. But the amount at the disposal of the First Lord of the Treasury for pensions is ridiculously small, and in the present temper of the community we can hardly imagine that a proposal to appropriate, say, a quarter of a million a year for the benefit of sufferers from the accidents of their work in civil life would be received with other than an outburst of economic indignation. Standing charges are already enormous, and sources of taxation are heavily burdened. Dreadnoughts are luxuries which have to be paid for, and the recent addition of Old Age Pensions-with which, of course, we are all thoroughly in sympathy-will place a heavy burden on the Exchequer for a long time. To look to the Government to do anything for the medical men who fall by the wayside is, therefore, we fear, to look in a direction from which no help is likely to come, even though, as we showed last week, some members are freely giving as much as onefifth of their income to the medical needs of the community. Thanks to the Workmen's Compensation Act, sufferers from industrial accidents and diseases are now provided for at the expense of their employers, but the medical man, being his own employer, in nearly all cases has nothing to gain from the Act- except to pay for injuries to his own servants. But though, as we have said, the practitioner is, in the eye of the law, his own employer, his real employer is the public, to whose service he devotes himself, and it is not unfair to expect it to render to him the same service which he renders to his own employees. That is to say, that it is a just and proper burden on the public exchequer to contribute to his support when, from accident or disease incurred in its service, he is laid aside, temporarily or permanently. The obligation, indeed, is different altogether from any similar one that might pertain to other workers, for, apart altogether from the private practice by which he supports himself, the medical man is continually rendering service to the State by his unpaid work to patients whom he knows never can or will pay, to hospital patients who are not expected to pay, and by performing functions, such as giving death certificates, which protect the weal of the State in one way or another. It is pitiable to think that with nearly every fresh class medical appointment, whether it be that of medical officer of health, or medical inspector of school children, the authorities categorically lay down that no retiring or compassionate allowance is attached to the post, and frequently that the appointment must be regarded as running for one or three years only. Almost more pitiable is it that these posts should be rushed after by numbers of highly qualified and experienced men, who seem to regard three or four hundred a year as the summum bonum of their ambition. With this trend in public opinion it is plain that the profession must rely more and more on itself and on its combined influence and fighting qualities. Salvation comes not from any point of the compass but from within, and loyalty to colleagues and solidarity of aim are the qualities that are needed. An example of what may be done in the way of charity to the profession is given by the late Mr. George Smith, M.R.C.S., L.D.S., of Manchester, whose will was published last week. His estate was sworn at £11,669, and, subject to several bequests, he left the residue in equal shares to the Royal Infirmary, Manchester, and to University College Hospital, London, to be used for the benefit, not of the patients, but of one or more of the surgical or dental staff who may be incapicitated from work by being infected by any puncture, or contracting blood-poisoning from examining or operating on patients, or conducting post-mortem examinations. This is a noble example and worthy of all imitation. Medical men often, after a life devoted to hospital work, leave any money they have to their institutions, but how much more acceptable would it be if bequeathed to those of their successors who are wounded in the battlefield of medicine, and without such help would probably find themselves stranded or dependent on the good-will of friends who can ill afford to support them.

# CURRENT TOPICS.

The Live Burial Bogey.

THE Society for the Prevention of Live Burial pursues its path with unabated vigour, in spite of the sandy soil on which their structure is raised. Time after time they have been asked for scientific evidence of the occurrence of live burial, but no absolute and convincing cases have so far been Of hearsay and presumptive testiforthcoming. mony there is an infinite amount, but on investigation it may be questioned whether any single alleged instance on record would suffice the critical demands of any careful observer. One of the common fallacious stories is the gruesome tale of sounds issuing from a coffin, presumably caused by the efforts of the resuscitated person to attract attention. It has long ago been pointed out by an author who carefully investigated the whole subject that the amount of air in an air-tight coffin would not suffice to keep a human being alive for many minutes. It is equally certain that life could not be maintained for more than a few brief instants without the performance of the respiratory function. From these premises it follows that no human being could recover animation after having been shut up in an ordinary air-tight coffin for more than a few moments. A few days since a grave was being filled up at Leigh, a village in Staffordshire, when rapping sounds were thought to be heard proceeding from the coffin. The undertaker speedily unscrewed the lid and sent for a medical man, who found nothing but a dead body, and no evidence that there had been any movement. The coffin was replaced, and as the grave was being filled up a second time rapping was again supposed to occur. Had the affair not been at once investigated it would doubtless have added another to the bogus stories quoted in support of the gruesome assumption that live burial is of frequent occurrence. The life of man is already surrounded by a sufficiency of trials and difficulties without adding gratuitous terrors to the list. Why should not the possibility of live burial be investigated by a responsible committee, say, one appointed by the Royal Society?

Registration of Nurses.

THE path of those who seek for the State registration of nurses has not been made easy. In the first place, the medical profession has always regarded the proposal of registration of nurses with some suspicion, as leading to the possible establishment and recognition of a rival order of practitioners. It will be remembered, too, that last year, when a Bill for the purpose was introduced in the House of Lords, and at the instance of the Government, Ireland was omitted from its operation, a tremendous outcry arose in that country. It was pointed out, quite correctly, that if there was to be State registration of nurses, the system should apply to the entire Kingdom. Finally, the Government had to give way. Now, however, a new difficulty has appeared. The nursing profession of Scotland, backed by the medical profession, is demanding exclusion from any English Bill, and is calling for Home Rule in this matter. In some points the scheme put forward by the Scottish nurses has advantages over the Bill which passed the House of Lords last session, but we hardly think the advantages sufficient to counterbalance the inconveniences of having different systems at work in different parts of the Kingdom.

Landlords and Insanitary Tenants.

So much has been heard of the evils of landlordism, especially in poor neighbourhoods, that an attack on their tenants comes with an attractive air of novelty. The bad landlord and the bad tenant together furnish a picture of slum desolation the description of which is familiar in the articles of the descriptive newspaper reporter. But the good landlord and the bad tenant is a combination that does not lend itself so readily to effective journalistic treatment. The point was raised recently at a meeting of the Midland Sanitary Inspectors' Association at Birmingham by Dr. Robertson, Medical Officer of Health for that city, who boldly asserted that the time had come for demanding powers to deal with dirty and destructive tenants. He was persuaded that a great amount of harm was caused to landlords by tenants who caused dilapidations, not only to their own houses, but to those of their neighbours. He deprecated any desire to whitewash landlords or agents, but he could not help feeling that there were a great many cases in which reasonably clean and decent houses were provided, but which were brought into a dilapidated and insanitary condition by the tenants. The opinion of this speaker was that the law should be altered in the direction of giving the landlord greater power than at present for getting rid of undesirable tenants. At present the landlord undoubtedly experiences great difficulty in getting sufficient evidence to support the application of an ejectment order. The law has, in point of fact, carefully regulated the relations between landlord and tenant, and on the whole its administration works with reasonable success. Hard cases are bound to occur at times even under the best-considered human institutions. We doubt if the existence of a certain number of dirty

destructive tenants would warrant any change in the existing law. Landlords must be prepared to take the good with the bad tenants in slum properties, just as they have to do with honest and dishonest tenants in middle and upper-class society. Reduced to its simplest terms, the monetary damage comes to much the same thing whether due to the loss of rent or to the damage to house property. The chairman of the inspectors' conference summed the matter up when he said that there were tenants who broke up the stairs and doors for firewood, and landlords who would not put on a coat of paint. There was much to be said on both sides, and betwixt them the sanitary inspector had his work cut out. At the same time, there had been a great improvement in the slum property of Birmingham. That happy result, happily more or less universal in the United Kingdom, is probably in no small measure due to the efficiency and sound technical education of the sanitary inspectors as the administrative officers of an enlightened system of local sanitation.

260 THE MEDICAL PRESS.

# Sanitation in Irish Schools.

We have more than once commented on the shockingly insanitary conditions which are characteristic of many of the primary schools in Ireland. In Belfast particularly the school inspectors have repeatedly drawn attention to overcrowding, bad ventilation, neglect of cleansing, and absence of closets. From a recent report we learn that, allowing the modest space of ten square feet to each pupil, the accommodation is insufficient in 27.7 per cent. of the Belfast schools. In only 48.3 per cent, is it ample. In one school where there is accommodation for 40 pupils the inspector found 112 present; in another where there was accommodation for 12, 36 present; and in a third, 80 children crowded into a space sufficient for 18. He gives the figures of several other schools where two or three times the proper number of pupils were present. The conditions throughout the rest of the country, though not quite so scandalous, give cause for grave dissatisfaction. It is impossible to calculate the injury done to the future of the country by bringing up the children in such surroundings. It is not merely the noxious effect on their own health that we consider, though we regard the health of a child as of much more importance than the learning he acquires at a primary school. In recent years lessons in hygiene have been introduced into the school curriculum. Can anything be more ridiculous and hypocritical than to give instruction in hygiene to children crammed by force into such filthy dens as the schools of Belfast? The force of example goes far, and it is no wonder that the slums of Irish towns show such a high deathrate when these are the conditions which Irish children are brought up to regard as normal or proper. We say without hesitation, that children would be better without any schooling than with the schooling they get under such circumstances.

# Medical Education in China.

An appeal to the nation is being made by the China Emergency Appeal Committee on behalf of the spread of Western education in China. It is supported by a number of distinguished philan-

thropists, under the presidency of that great Chinese authority, Sir Robert Hart. The catholicity of the movement may be gathered from the fact that its supporters include, amongst many others, the Lord Mayor of London, Lord Alverstone, Lord Strathcona, Sir Albert Spicer, Messrs. A. T. Buxton, Robert Barclay, George Cadbury, Samuel Morley, J. S. Fry, the Archbishop of Canterbury, T. H. Warren, Vice-Chancellor of Oxford University, Sir William Turner, Vice-Chancellor of Edinburgh University, Sir Donald Macalister, Vice-Chancellor of Glasgow University, Principal Fairbairn, the Rev. T. Scott Lidgett, the Rev. Ian Maclaren, and Mr. C. T. Studd. The general idea is to spread Western education by the training of Chinese students and the development of a central university. As regards medical colleges, it is proposed to place on a thoroughly sound footing four of the existing medical schools that have been established in connection with the mission hospitals. Quite recently a medical school has been founded at Peking, which has been recognised by the Government and whose students are privileged to obtain a diploma to practice from the Imperial Board of Education. Needless to say, the present methods of Chinese native medical practitioners are barbarous and cruel in the extreme. In fact, trained medical men are unknown outside the missionary hospitals, save in the case of the navy and of a portion of the army. £40,000 is asked in aid of medical training colleges. While the Appeal Committee intend to carry on their work in a spirit of Christianity, it is important to note that their work is one of education and not of evangelisation. An important public meeting was held yesterday at the Mansion House, London, when the whole scheme was fairly launched.

# A Poor-Law Tragedy.

FROM time to time we are sharply reminded that bumbledom, with its red-tape officialism, is still in our midst. The Midwives Act (Special) Committee have advised the London County Council that the several boards of guardians within the county should be required to pay the fees of medical mencalled in by midwives, and that the Local Government Board be asked to take action in a similar direction. The Committee quote the following tragedy: -A midwife was called at 8.30 p.m. to a case in the Hackney Union. Seeing that the patient, a young woman, was very ill, she went for a doctor, and returned with him at 10.15 p.m. He advised the obtaining of an order from the relieving officer for the attendance of the parish doctor. Then the business of the circumlocution office began. The nurse called upon the parish doctor in whose district the patient's friends believed they lived. He said the patient's house was not in his district, and referred the nurse to the relieving officer of another district. This officer, when called upon, said the house was not in his district, and in his turn referred the nurse to a third relieving officer. being now very late, she went to officer No. 3 at 9 a.m. next morning, and found that he had left for his office. She then went to the parish doctor for the district and asked him to see the patient. He said the father of the patient must obtain an order from the relieving officer, and he would visit. the case at eleven o'clock. The nurse returned to the patient's house, sent the father to the relieving officer, and herself gave all her attention to the patient. The patient died at 12.15 p.m., two minutes before the parish doctor arrived. details are eloquent in their condemnation of a system which, in these days of telephones and instantaneous communication, makes such a tragedy possible.

The Measles Epidemic.

FROM all parts of the Kingdom news has come of wholesale epidemics of measles. Schools have teen shut, many deaths have been recorded, and local health and education boards have been awakened to the gravity of the situation. In many instances public notices have been issued warning parents as to the methods of infection and instructing them in the recognition and the special risks of the disease. As the period of incubation varies from nine to sixteen days, during the whole of which time-especially the two or three days before the appearance of the rash—the patient is infectious, it seems hopeless to attempt to isolate sufferers with any chance of success. The way to stamp out measles is probably by an absolute system of notification, isolation, and quarantining of exposed persons. At present any counsel of the kind is one of perfection, standing upon an unapproachable On the other hand, as every medical practitioner knows, measles is a comparatively harmless malady when properly nursed, a fact that renders the special education of parents upon the point invaluable. The early recognition of the disease and the keeping of the patient warm in bed would almost, if not altogether, prevent the greater propagation of complications such as bronchitis, pneumonia and middle car troubles. Another way in which local authorities may do much to check the spread of measles is by urging upon citizens the necessity of the thorough disinfection of a patient's environment. The publication of detailed statistics of the mortality due to measles, as compared with scarlatina, enteric fever and other infectious diseases, usually regarded as far more deadly in their nature, would also help in impressing upon the mind of the man in the street the necessity of treating measles with due respect.

# PERSONAL.

THE PRINCE AND PRINCESS OF WALES, on March 10th, paid a visit to the Royal College of Surgeons of London. Their Royal Highnesses were accompanied by Sir Frederick Treves, and were received at the College by the President, Mr. Henry Morris, the Conservator, Professor Arthur Keith, and the Secretary, Mr. S. F. Cowell.

During the afternoon of March 12th, the Prince of DURING the atternoon of March 12th, the Prince of Wales drove to University College Hospital, Gower Street, and made a tour around the different departments and wards. His Royal Highness, attended by the Hon. Derek Keppel, was received by Sir Thomas Batlow, Bart., M.D., K.C.V.O., the resident medical officer the mattern and the acting secretary; who conofficer, the matron, and the acting secretary; who conducted him round the hospital. The Prince also went through the new buildings of the medical school, and the nurses' institute.

THE DUKE OF MARLBOROUGH, the President, took the Chair at the annual Court of Governors of the Royal National Orthopædic Hospital, held on March 4th in the hall of the new Out-Patient Department.

THE LORD MAYOR presided at the annual meeting of Governors of the Royal Hospital for Diseases of the Chest, City Road, at the hospital on Monday last.

MR. JAMES CANTLIE, F.R.C.S., has been appointed a Knight of Grace of the Order of St. John of Jerusalem.

PROFESSOR KIPPING has been awarded the Lougstaff Medal of the London Chemical Society for 1909. This medal is given triennially for excellence in research

DR. WALTER RAMSDEN, M.A., M.D., Fellow and Junior Bursar of Pembroke College, has been chosen Senior Proctor for the ensuing year in the University

MR. CHRISTOPHER ADDISON has been appointed Examiner in Anatomy to the University of London, and Chairman of the Board of Intermediate Studies of the same University.

THE National League for Physical Education and Improvement has organised a series of five lectures to be given on Thursdays at 3.30 p.m. at 35 Holland Park Avenue.

FROM the funds placed at the disposal of the London School of Tropical Medicine by Sir John Craggs, grants have been made to Dr. B. M. Wilson, of Fiji, and Dr. R. Howard, of the Universities' Mission to Central Africa.

THE annual conversatione of the West London Post-graduate College, Hammersmith Road, London, W., will be held on Wednesday, March 24th, at 8.30 p.m. All past and present members of the College are cordially invited.

On Friday next Captain C. F. Craig, of the United States Army, will read a paper before the Society of Tropical Medicine and Hygiene, at the Medical Society's Rooms, at 8.30 p.m. His subject will be, "Observations of the United States Army Board for the Study of Tropical Diseases in the Phillipine Islands,3

At the annual meeting, on March oth, of the Liverpool Maternity Hospital and Ladies' Charity, Sir William Hartley offered to erect and equip a new hospital at a cost of £15,000. The conditions were that the committee should find a site, and that an endowment fund of £20,000, limited to fifteen years, should be raised. Sir William was thanked for his generous offer, and a contribution of £1,000 towards the endowment fund was promised by Mr. Sutton

Dr. Nicolas Weliaminoff, Privy Councillor of State and Professor of Surgery at the Imperial Military Academy of Medicine, St. Petersburg, having been unanimously elected an Honorary Fellow of the Royal College of Surgeons, was presented to the Council on March 11th, and signed the roll. The distinguished Russian surgeon, who is at present on a visit to this country in attendance on the Empress Marie Feodorovna, was nominated for election in 1900, when the Honoray Fellowship was instituted, but was unable to come to England at that time.

At the same meeting the President reported that Sir Gilbert Blane medals, conferred every two years on two medical officers of the Royal Navy, "for skill on two medical omcers of the Royal Navy, "for skill and learning in the exercise of their professional duties," had been awarded to Staff-Surgeons Charles Rowley Nicholson, of His Majesty's ship Egmont. and Arthur William Bligh Livesay, M.B., His Majesty's ship Bonaventure.

# A CLINICAL LECTURE

ON

# HEMIPLEGIA DUE TO SYPHILITIC ARTERITIS.

By Prof. G. MILIAN, M.D.,

Physician to the Paris Hospitals.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

HEMIPLEGIA of syphilitic origin is in most instances due to arterial lesions, and in such case the attack presents certain distinctive features consequent upon the mode of production of obliterative endarteritis, which is the underlying cause thereof. This does not obstruct the lumen of the vessel all at once, but in a steadily progressive manner, so that the softening that ultimately follows does not take place immediately. There is a preliminary period of uncertain duration during which we meet with functional disturbances, with what Potain used to call meiopragia, while all the while the process of arterial obliteration is going insidiously on. Then by-and-bye the obstruction becomes complete with consequent cerebral ischæmia. This is the meiopragic stage, of variable duration, which gives cerebral arteritis of syphilitic origin its peculiar characteristic physiognomy.

I have just mentoned that the symptoms of cerebral arteritis do not set in all at once; they supervene one or two at a time, in succession, the progress being more or less rapid according to circumstances. The course of the disease may be roughly divided into three periods: (a) A period of functional disturbance corresponding to invasion of the vessel, during which the patient complains of painful or other manifestations, these, however, not having any direct bearing on the terminal symptoms; (b) a meiopragic or paretic stage corresponding to partial obliteration of the vessel, during which we get in an attenuated, incomplete, intermittent form the terminal symptoms; and, lastly (c) the paralytic stage, corresponding to total obliteration of the vessel and consequent softening of the brain.

First Period.—The first symptom to appear is headache, a premonitory symptom which, by its severity, often places it in our power to avert irremediable mischief by constraining the patient to apply to his medical adviser for relief. This headache presents much the same character as the syphilitic headache—viz., it is fixed, severe, is worse at night or in the evening, and is refractory to analgesic medication. This is common to all syphilitic affections of the encephalon. It may exist a long time—six, eight or ten months, for instance, before any signs of hemiplegia make their appearance. Fournier mentions the case of a woman who suffered from violent headache for upwards of four years, incessantly, and the headache already very intense during the first three years, became excruciating during the fifteen or eighteen months that preceded the onset of the paralysis.

There may also be sundry subjective symptoms affecting the special organs of sense: dazzling of the sight, blurred sight and sparks in the visual field, with noises in the ears, humming, &c.

The patient may, in addition, be conscious of some impairment of memory with diminished aptitude for work, associated with mental depression, prostration and drowsiness. These premonitory symptoms are rarely wanting.

Second Period.—At this stage of obliterative arteritis the symptoms begin to get more pronounced and are directly dependent on the ischæmic troubles of the cerebral regions involved. The most frequently observed symptoms—those that constitute the common form of cerebral syphilis, are hemiplegic manifestations, accompanied or not, as the case may be, by aphasia, according as it is the right or left side that is attacked.

The immediately-preceding meiopragic phenomena may be either sensory or motor. The sensory disturbances, the existence of which need not surprise us, seeing that the sensory area of the cerebral cortex is in juxtaposition to the motor area, consists in numbness of the limb with a feeling of cold and tingling in the extremity, but these manifestations are, as a rule, more or less fugitive. In some cases the sense of touch is blumted, the patient feels as if he had a glove on, while, in others, there is hyperæsthesia of the region that is to become hemiplegic.

Fournier relates the case of a patient who, three weeks before an attack of left hemiplegia, complained of marked hyperæsthesia over the anterior surface of the left thigh, while the posterior surface of the limb, on the contrary, was anæsthetic. This observer insists on what he calls the "cerebral pains in the limbs," a grave symptom, in that it is the precursor of hemiplegia.

Personally, I must confess that I have not observed anything of the kind, and I cannot admit that it be possible to prognosticate hemiplegia on the strength thereof, since the pains do not present any particular characteristic feature which would enable us to differentiate them from the pain of any deeply-seated local syphilitic accident that is not accessible to palpation. They are merely vague local pains occurring in a limited region of the body, in a limb or the extremity of a limb, going and coming, appearing and disappearing, and they are usually described as rheumatoid, neuralgic, osteocopic, &c. They tend to recur constantly in the same region, and then one day this region becomes hemiplegic.

The motor phenomena are more characteristic of threatening paralysis. We get tremors, limited to a limb, sometimes associated with muscular twitchings. The commonest symptom is fugitive weakness of this or that part or limb: arm, hand, lower limb, &c. The hand gets clumsy, the grasp is lax and writing becomes difficult. A patient of mine complained to me that when out walking she was continually letting her umbrella drop, in fact, that she could not grasp it with her right hand. The very next day she was seized with brachial monoplegia on that side, soon followed by complete hemiplegia with aphasia.

One of Fournier's patients had several fugitive attacks of lingual paresis lasting a few minutes; later on he had numbness of the left arm. One day, when out shooting, he noticed all at once that he was unable to hold his gun in the left hand. This scared him, and he made off home and went to bed and to sleep, and when he awoke things were all

right again, but a few months later he was stricken with hemiplegia.

Sometimes it is the lower limb that is seized with sudden weakness and gives way, causing the patient

to stagger or fall down.

In the same category of symptoms must be placed fugitive attacks of aphasia, for no one nowadays discusses the existence of a special syphilitic form of aphasia. Aphasia is due to changes in a given region of the brain and not to any particular morbid lesion. The attack of aphasia may be followed in a few hours, days, or months, when transitory, by right hemiplegia. In this case it is motor, and not sensory, aphasia. But we must beware of errors of diagnosis. Fugitive aphasia is but rarely the prelude of hemiplegia due to cerebral arteritis. On the contrary, it very frequently ushers in general paralysis, but, to put it more clearly, it is often the flagrant symptom that reveals to us the existence of latent general paralysis. As a matter of fact, in general paralysis it is anarthria rather than aphasia, of defective articulation rather than loss of word-memory. It is accompanied by lightheadedness and restlessness, indicative of irritation of the cortex consequent upon meningo-encephalitis.

Aphasia is to syphilitic arteritis what the shadow is to the body, and follows its evolution step by step. In conjunction with the hemiplegia, it forms a very distinct entity with a symptomatology peculiarly its own, and without any collateral manifestations, such as convulsive attacks, excitement. delirium, &c. Take, for instance, the case of a young man, æt. 23, who had contracted syphilis six years previously and had not undergone any treatment worthy of the name. At a ball, while dancing a quadrille, he was seized with a most extraordinary weakness and found himself unable to articulate a single word, in fact, he would have fallen to the ground had his partner not held him on his feet. He was conveyed home without having been able to articulate anything beyond a few disconnected monosyllables. He was put to bed and went to sleep, but on awakening the following morning he was completely aphasic, with right hemiplegia.

Paralytic Period.—Here we are confronted with fully developed hemiplegia; this, at any rate, is the commonest terminal symptom, and it obtains in at least 50 per cent. of cases of cerebral syphilis.

The hemiplegia affects three distinct forms: General, i.e., complete from the onset; general, but

progressive; successive, or by stages.

General and complete from the onset is the form of constituted hemiplegia ne varietur. From the earliest moment the paralysis attacks half the body, face, body, upper and lower limbs—that is to say, it is general. Then, too, it is complete, no movement of any kind being possible. This form is somewhat rare.

The general, but progressive, form also affects the entire half of the body, leaving no segment untouched (general), but the paralysis may not be absolute. Certain movements may still be performed in the affected areas, so that, in fact, it enly amounts to paresis. Not until later—a few hours or a day or two—does the paralysis become complete. This form is more frequent than the preceding, but, nevertheless, it is not the usual form.

Successive and by stages, this is the normal, usual form that is met with in association with obliterative arteritis. The paralysis first shows itself in a limb or segment of a limb—the hand, for instance. On the following day it extends to the face, and later on to the lower limb, until the hemiplegia is

complete. In short, it is hemiplegia by a succession of monoplegias.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Hor ce Law, M.D., Throat Surgeon to the Adelaide Hospital, Dublin. Subject: "Tertisty Syphilis in Upper Air Passages."

# ORIGINAL PAPERS.

THE DIAGNOSIS AND TREATMENT OF CHRONIC ULCER OF THE STOMACH AND DUODENUM. (a)

By ALEXIS THOMSON, M.D., F.R.C.S. Edin.,

Surgeon, Royal Infirmary, Edinburgh.

THE paper was based on a consecutive series of 50 cases in which a chronic ulcer was demonstrated at the operation. Of the 50 cases, 22 were duodenal and 28 gastric ulcers, the sites being as follows:-Pyloric ring, 16 (32 per cent.); lesser curvature, 12 (24 per cent.); first part of duodenum, 17 (34 per cent.); multiple ulcers, one being duodenal, 5 (10 per cent.). He estimated the proportion of ulcers met with on the so-called anterior wall of the stomach as 95 per cent. of all cases. Thirty of the patients were males, and twenty females; the gastric ulcers were equally divided between the two sexes; males preponderated among the sufferers from duodenal ulcer in the proportion of eighteen to four. In the gastric ulcer patients the average age onset of symptoms was 32, of the duodenal ulcer patients 38 years. A noteworthy feature in the histories of nearly all cases was the occurrence of long periods of remission from all symptoms. In three patients there was no pain at all, and in another three the pain was trifling. Constant pain was not likely to occur in cases of ulcer of the lesser curvature. As a general rule, the pain of lesser curvature ulcers was situated to the left of the middle line, of pyloric ring ulcers in the middle line, and of duodenal ulcers to the right of the middle line, but there were many exceptions. Often he had asked a patient, just before beginning to operate, where the painwas, and had been assured that it was under the left costal margin, yet, on opening the abdomen, a duodenal ulcer had been found. In most cases pain was aggravated by taking food, and it was generally supposed that the reason for this was that the ulcer was irritated by the acid gastric juice. He doubted this explanation on the following grounds: -Pain was rarely a prominent feature in acute gastric ulcer. The pain occurring in disease of other hollow viscera is due to muscular contraction. He believed that the pain of gastric and duodenal ulcer was due to peristalsis caused by food, not to the irritation caused by the acid gastric juice. Pain came on from a half to one hour after food in cases of ulcer of the lesser curvature, from one to two hours in ulcer of the pyloric portion, and about three hours after food in duodenal ulcer. In most cases of duodenal ulcer the pain was quite uninfluenced by the nature of the diet. Sometimes pain was re-lieved by taking food, as in the case of "hunger pain," in which, when the stomach was empty, the patient suffered from epigastric discomfort and pain, at once relieved for the time being by eating. In explanation of this symptom, which occurred in cases of duodenal ulcer, it had been supposed that

<sup>(</sup>a) Paper read at the Edinburgh Medico-Chirurgical Society, March 3rd, 1909.

the pain was due to the acid contents of the stomach flowing over the ulcer; when food was swallowed the pylorus closed and put a stop to this. He thought, however, that it was quite possible that it was simply due to the empty stomach pulling on the pylorus and tending to draw it to the left. The relation of the pain to the attitude of the patient was inconstant; there was no evidence to show that relief to the pain by lying either on the face, or on the back, was of any localising value— the majority of the ulcers met with were on the Tenderness was anterior wall of the stomach. chiefly due to the existence of adhesions. Vomiting was present in 42 cases (84 per cent.); the cases in which it was missed were chiefly duodenal ulcer. In 29 cases (58 per cent.) there was hæmatemesis; in 11 there was also melæna. The great majority of cases showed an excess of free HCl; in four cases of ulcer of the lesser curvature free HCl was absent. Butyric and lactic acids were of little importance in the diagnosis of ulcer or its seat.

Treatment.—In most cases chronic gastric ulcer was incurable without operation. Of the two operations, resection and gastro-enterostomy, the latter was preferable. Resection should be restricted as far as possible; it was an extremely difficult operation as compared with resection of cancer, and the mortality was high. On the other hand, with modern methods, gastro-enterostomy should not have a mortality of much more than I per cent. He had to report the following results of fifty operations:-Resections, 3. One operation death; 1 perfectly well 3\frac{1}{4} years later; 1 2\frac{1}{3} years later, has still some pain and flatuience. Gastro-enterostomies, 47. Three operation deaths in the first 15 of the series, making a mortality of 6.4 per cent.; of those who survived I has been lost sight of, and 5 have died at various periods from other than stomach causes. Of the 38 survivors 1 is slightly anæmic, 1 has some distension, 2 a little flatulence and occasional bilious attacks; the rest unanimously record marked increase in weight and complete freedom from stomach symptoms, 25 of these being reported on from 1 to 71 years after operation, the remainder within the year.

# SOME CASES OF HYDATID DISEASE OF THE LIVER. (a)

BY G. P. NEWBOLT, F.R.C.S.ENG.,

Examiner in Clinical Surgery, University of Liverpool; Surgeon, Royal Southern Hospital.

DURING the last few years ten cases of this disease have come under my observation, and as they are not so very common in this country, some observations upon them may be of interest. Nine out of the ten patients came from North Wales, and in the majority of these a history of living on a sheep farm and of contact with dogs was obtained. The one exception had never been out of Liverpool. Four were in males, and six formula in formu and six in females. The youngest was 8 years old, and the oldest 54. Jaundice was present in three cases on admission, and has been transient in others; operation was carried out in each instance, one patient dying. In one instance the cyst was reached through the chest wall, in the others by means of an abdominal incision. The operations were performed in one stage, the hydatid removed where possible, and the edges of the capsule brought to the abdominal wall with strong silk, large drainage tubes being inserted. On two occasions two cysts were discovered.

Diagnosis.—Usually the diagnosis was easily made, but in Case to it presented difficulties; in fact, even after the abdomen was opened, matters were not quite clear at first. The patient, a male, æt. 31, had been

ill for eight months prior to admission; he had been jaundiced for three months, and complained of a good deal of pain in his liver, which was considerably enlarged, both lobes being affected. The pain was accompanied by attacks of vomiting and sweating, whilst under observation his pulse was 94 and his temperature 100°. On examination the left lobe of his liver was of stony hardness, considerably enlarged downwards, and very tender. The right lobe was enlarged upwards and downwards, and also felt very hard; there was no sense of fluctuation, and no thrill. The jaundice, though considerable, was not complete, and the stools were not clay-coloured, though the urine contained bile. There was no history of syphilis, nor did any improvement take place under iodide and mercury. As the pain became so much worse and the temperature kept up, it was thought wiser to explore. On the day before exploration he had one of his acute attacks of pain, and could only lie curled up on his right side. The attack simulated gall-stone colic. On March 4th, 1908, I opened his abdomen in the middle line, exposing the liver, which was partially shut off by adhesions; there were some hard nodules on the surface of the organ, and it looked very much as if the man was suffering from malignant disease. However, on puncturing one of these projections, a small amount of pus escaped, but nothing further, and this did not account for the symptoms. I next explored the left lobe with a needle passed from the middle line, and evacuated a large hydatid cyst with clear contents; but the temperature, pain, and sweating pointed to the presence of something more than this, so I pushed a needle deeply in at the point where pus had first escaped, and after going some 3 in. struck a suppurating hydatid cyst. This I opened with dressing forceps, introducing a large rubber tube, through which a number of daughter cysts and portions of cyst wall escaped; hæmorrhage was free, but the tube and a plug of gauze restrained it. The man was put back to bed, and soon after collapsed rather badly, but continuous saline injections per rectum restored him, and next day he was better. The left cyst soon became obliterated, but the cavity on the right continued to discharge large amounts of bile and cysts for several weeks. In order to demonstrate the size of the cavity a rubber tube filled with mercury was passed and the patient Xrayed; the tube was found to occupy the greater part of the posterior portion of the right lobe of the liver. The question of diagnosis was the most interesting The amount of pain was far greater than in any of the other suppurating cases I have seen; in fact, it resembled the pain of a perforating viscus. Even after opening the abdomen there was no sense of fluctuation. In tapping the cysts the needle was arrested by a dense fibrous wall, necessitating considerable force to make it penetrate. Evidently a slight leak had occurred, leading to the superficial collection of pus and the localised peritonitis shutting off the peritoneal cavity in the median line. The possibility of the disease being malignant or gummatous was kept in mind when exploring. From the amount of bile which escaped immediately after operation, a large duct was either involved by the cyst or opened at the duct was either involved by the cyst or opened at the time of operation. The following case bears also on the question of diagnosis. Mary W., æt. 9, was sent up from the country with a tumour of the right side in the hepatic region, supposed to be a hydatid. After examination I had very little doubt that I had to deal with a hydatid cyst involving the right lobe of the liver. The tumour gave a distinct sense of fluctuation; it was painless, and apparently incorporated with the liver, but there was no thrill; it projected backwards into the right loin, and the liver dulness did not extend upwards. A nodule the size of a hazel nut could be felt in the abdomen below the umbilicus. The ward examination of the urine gave it as normal. On exploration the tumour proved to be a small roundcelled sarcoma of the right kidney growing forward and lying in contact with the right lobe of the liver. It was soft and vascular, so much so that after removal of a piece for examination I had to plug the wound with gauze for two days before closing it up. The

<sup>(</sup>a) Read before the Liverpool Medico Chirurgical Society, July, 1908.

nodule in the abdomen proved to be a gland, and segregation of the urine showed that a few blood-cells were present. No attempt was made at removal, as the abdominal glands were involved, and the child died six weeks later. The vena cava was pressed upon, and there was a secondary growth in the brain.

The cysts, however, do not always point forwards,

but may present towards the chest, and we then have a different state of things. This is well shown in Case 2. Alice P., a girl, æt. 12, was transferred to my care for the purpose of exploratory operation on August 7th, 1900. She had been ill for some months, suffering from shortness of breath and discomfort in the right side. Her abdomen was swollen in the upper part, and retracted below. The margin of the liver was visible during respiration. The liver dulness in the mammary line extended from the upper border of the third rib to 21 in. below the costal margin. The margin of the lung expanded about an inch on inspiration over the dull area. Breath sounds were weak over the dull area in the axilla, elsewhere fairly well marked. Vocal resonance and fremitus were conducted. Respirations were 32, the pulse 90, and the temperature varied, often being 101°. On palpating the liver there was distinct but regular enlargement of this organ below the ribs, but nothing like a cyst could be made out. The conclusion arrived at was that there was a hydatid in the liver pushing the lung upwards, and an exploring needle drew off pus. On August 7th, 1900, under chloroform, I aspirated through the eighth inter-space in the mid-axillary line, and got clear yellow fluid which had a very foul smell. I again put the needle through the ninth interspace, with a similar result. I therefore removed a piece of the ninth rib, and opened the chest. The lung, which was healthy, at once retracted, and the wall of a cyst bulged up at the lower part of the wound. More rib was resected in order to get a free exposure of the parts, and the cyst was again aspirated. Having drawn off some 8 oz. of fluid of the same character as before, I caught the now flaccid wall of the cyst and drew it up into the wound, stitching it around to the soft parts so as to shut off the cavity of the chest. On opening the cyst freely a large quantity of fluid escaped, with numbers of cysts of all sizes, some of them containing pus. I was able to get away the whole of the endocyst in one piece, and drained the cavity left with two big tubes packed around with gauze. The girl stood the operation well, but her temperature ran up to 1020, her pulso became 120, and her respirations 64. For several days she gave rise to much anxiety, but eventually made a good recovery, leaving hospital in November. doubt the pus obtained when exploring was due to one of the smaller cysts being punctured. The opening of the chest and interference with the diaphragm probably gave rise to the quick respirations and general upset after the operation, and I have seen the same condition of affairs after opening a liver abscess in the same way. In the majority of my cases the hydatids were painless until they suppurated or until they pressed upon important structures. Many of the patients had jaundice at some time or other, and several complained of pain in the right shoulder and of losing flesh. Percussion of the convex upper edge of the liver and an X-ray view of the shadow thrown by the liver, in most instances enable us to diagnose between a cyst and a pleuritic effusion. In addition we may have the descent of the margin of the lung over the cyst, varying percussion note.

Treatment.—In dealing with the cysts that have come under my care I have adopted one method only, and that is to expose the cyst by an incision made, whenever possible, over the most prominent part of the tumour, to open the cyst, empty it and drain it. The majority of the cysts were operated upon through the abdominal wall, i.e., nine out of the ten. If after exposing the cyst it is found to be adherent, so much the better; if not, it must be packed off from the surrounding parts with gauze. The cyst is then aspirated and the fluid contents drawn off. Anyone who has observed the force with which the fluid is ejected from a tense hydatid cyst must realise the danger of

exploring one of these tumours without having first exposed its wall and shut it off from the abdominal cavity; the fluid often escapes not only through but by the side of the needle used. Again, in Case 6, the hydatids apparently were dead, for the cyst had been noticed to be getting smaller, and on aspirating nothing escaped; yet a free incision revealed a cyst full of hydatids, without any free fluid—here the preliminary exploration with a needle would have been very misleading. When the greater part of the fluid has escaped, the cyst, if superficial, can be drawn up into the wound, freely opened and emptied. All the daughter cysts are removed, and as a rule the endocyst comes away; the edges of the cyst are then fixed to the margin of the abdominal incision by strong silk sutures cut long so that they can be used as retractors when dressing the wound. The gauze packing is removed from the abdomen as the cyst is stitched up. The cavity is packed with gauze, and later on kept open with a large rubber tube. The healing process is slow if the cyst is large, but it is safe and usually unattended by complications. A large cyst takes about three months to close up soundly, but the patient is generally able to get about some four or five weeks after operation. When the cyst is deeply situated in the liver the method is slightly different. Having exposed the liver, shut it off from the abdomen, and located the cyst with a needle, a long pair of dressing forceps is pushed along the exploring needle. Having established a track, a half-inch drainage tube can be passed by means of dressing forceps; this will drain the cyst perfectly well, and if necessary larger tubes can be inserted a few days later. The gauze packing which was used to shut off the abdomen is left for two days and then removed. Daughter cysts will continue to escape for some days, and the temperature will show if there is any retention.

I usually irrigate the cavity after the first dressing. In one of my cases in which the cyst was situated low down near the anterior margin of the liver, I was able to pull it up into the wound and remove about half of its anterior surface, but I have never adopted the operation of enucleation, the mortality of which is given at 17 per cent. If the cyst is small, the cavity will soon close whichever method is adopted; and, if large, the obliteration of the cavity by means of sutures must be both difficult and dangerous. secondary drainage has had to be performed in some of the cases so treated, the safe and sure method of drainage from the first is surely to be advised. one should be careful when operating to avoid soiling the edges of the wound with the contents of the cyst is well shown by Case 5, in which when a large cyst was opened several of the daughter cysts escaped in the wound. The abdomen was shut off, but the wound was an extensive one, and, although carefully washed out, implantation must have occurred, for a year later the patient returned to me with a cyst about the size of a pigeon's egg situated at the lower end of the scar. This was excised, and there was no further trouble. It is well, therefore, to protect the edges of the wound with gauze whilst operating. In those instances in which the wall of the cyst has become calcareous, the convalescence is likely to be a very tedious process, but they seem to heal. In one of my cases the posterior surface of the cyst was covered with calcareous plates. I tried to move one of these, but failed to do so. The recovery was very slow, but the cyst had existed for a long time before operation was performed. In cases in which the hydatid presents towards the chest wall it should be opened in this situation. If low down, the cyst may be reached below the reflection of the pleura. In the one instance I have experience of, the healthy chest was opened and the cyst wall, formed of pleura, diaphragm, and cyst, was fixed in the wound after removal of a portion of the ninth rib. It was then drained. I have recently seen a second case in which the same condition is present, but here I shall go lower down and avoid opening the pleura if possible. No doubt in some of these cases the two layers of pleura are adherent from pressure of the cyst, and all that is needed is a simple incision, with, possibly, removal of a portion of rib to give free drainage.

In conclusion, I have to thank my colleagues, Dr. William Williams, Dr. Macalister, and Dr. Lloyd Roberts, from whose wards the majority of the cases have been transferred, and to whom I am indebted for their valuable opinions.

# STATE CURE OF LEPROSY IN NORWAY AS IT AFFECTS OTHER COUNTRIES. (a)

BY ALBERT S. ASHMEAD, M.D.

[SPECIALLY CONTRIBUTED TO THE MEDICAL PRESS AND BY THE AUTHOR.] CIRCULAR

I HAVE spent a good deal of money on the private investigation of immigration of Scandinavian leprosy, and therefore can speak advisedly on some matters concerning it. I have devoted a great many years of my life to the special study of the disease in many lands, and know the views of a number of men who are eminent as leprologists. As one of the provisional committee of the Berlin Leper Conference—Hansen, of Norway, and Goldschmidt, of Funchal, Madeira, being the other members—I was prominent, in the contest between the strong contagionists and those who opposed their plea for a declaration favouring obligatory isola-

tion of all lepers.

The men of Russia and of France stood, with Goldschmidt and myself, in our demand that that conference should be held at Moscow, in a country where the leprologists are strong advocates against facultative isolation. The leprologists of Great Britain, a non-contagion country, wanted the conference to be held in London. But as they demanded that the Prince of Wales (now King Edward VII.), a strong anticontagionist, should be president of the congress, we would not agree and stood loyally to Russia. Hansen. would not agree, and stood loyally to Russia. Hansen, a member of our committee, then withdrew from it, when he found that we were about to issue our call for the meeting at Moscow, and joined in with the other Scandinavian countries, especially Denmark with Germany, and precipitately called the conference for Berlin. He was most interested in obtaining from the conference a declaration for facultative isolation of ispers, as practised in the Mixed Law of Norway. He appeared the London men by accepting Virchow as President of the conference, Virchow being a non-contagionist. When the conference was called to order, through Oscar Lassar of Berlin, I introduced a resolution for international unity of action regarding all matters concerning lepers, and especially intended to restrict the Inspector-General of Norway, Armauer Hansen, from shipping, or allowing to be shipped, lepers and leper families from his country to the United States, as had been going on for many years. Of course, Hansen led an attack against the proposal. I was defeated, and his original plan of conquering leprosy in his country by his faulty facultative law has been allowed to complete itself. In my investigation of Scandinavian leprosy in the United States, I found that surely (perhaps more) 316 full-flown lepers, known to the authorities of Norway to be lepers, had been allowed to emigrate to this country, and 175,000 leper families, in each of whom one or more lepers had been found, had been shipped as emigrants to America.

Many, if not most, of these families surely carried the latent germs, or perhaps suspicious, or as yet undeclared cases of the disease. Besides, the operation of the same law, in Iceland, put in effect through Ehler's efforts (a great admirer of Hansen and everything pertaining to him) has deluged Canada's North-West Provinces, as Dr. Smith, of Tracodie informs me, with many lepers. Our own North-West, Middle States, the Dakotas, and some other States, have also received through Winnipeg, a facultative centre of leprosy, a number of Ehler's Icelandic lepers. Facultative isolation is responsible for all this emigration evil of leprosy to the United States. Of greatest im-

portance, then, to this country, directly connected with the transference of these latent germs by the successful operation (for Norway) of Hansen's Mixed Law of isolation and its adoption by other countries, is the question-whether the disease is contagious? One-half of the population of Norway has been permitted to come here, while Hansen was being glorified for the gradual eradication of leprosy from his country. And now, in his honour, a second conference on leprosy has been called to meet at Bergen next August. It is, therefore, of supreme moment to learn whether this transference of 900,000 Scandinavians has not been the main factor by which Hansen has almost com-pletely conquered the Norwegian evil. Norway is a country with only 2,000,000 population. There are left behind there only 500 lepers to be cured by the operation of Hansen's facultative law of isolation. Perhaps when he has shipped here the remainder of his leprous families, there will be no lepers found in Norway. Two of the three lepers asylums in Norway have been long closed, as there was found to be no further need of them as Harsen's law was successfully operating "In closed, as there was found to be no further need of them, as Hansen's law was successfully operating "In 1920," he says, "there will be no more lepers in my country." "If you seek my monument, look about you." By that time all his lepers will be dead, and the suspicious ones translated to the United States.

We therefore must study two questions pertaining to leprosy with deepest diligence—contagion of the disease, and its epidemiology. Let me state here what is known and believed in by men of science who have treated leprosy, and nothing else. It is our "confession of faith," and those who subscribe to it will enter the leprological heaven. But those benighted heathen scientists, like the dermatological counsellors of our Roard of Health, who have condoned the non-isolation of lepers in New York, and who have refused the benefits of obligatory segregation, are condemned to the bottomless pit of utter leprological darkness. Most leprologists who have seen service in countries where leprosy has become epidemic believe in the following

Leprological Creed :-

LEPROLOGICAL CREED.

We believe First: That leprosy's invasion of a virgin country, as is shown by its history from immemorial past, in every situation, is divided into three stages: first, one of sporadicity, when only imported cases are found, scattered and appearing singly from time to time, with longer or shorter intervals, and without any connection the one with the other. period lasts in every country from 50 to 100 years.

Second: That there comes now a stage of endemicity, quietly and insidiously, unexplainable, when cases are discovered, first slowly appearing in succession, and then more rapidly, among those inhabitants who have never been away from the country. This stage lasts from 100 to 150 years. It sometimes takes on an appearance of regression, when only those leprologists who really know the habits of the disease are not deceived by it. For instance, at Abbeville, Louisiana, a very old endemic centre of leprosy, Dr. Edwards, a member of the State Board of Control, writes me, under date of November 2nd, 1908, as follows:—"There appears to be a certain amount of periodicity attaching to the outbreaks which have occurred in this parish in the last fifty years, the disease appearing with uniform regularity about every ten years, and each time the outbreak occurs there has been a period of several years during which time not a case of the disease is known to have existed in the parish. It is now about time for another outbreak. and I am more or less on the qui vive in consequence.

A like peculiarity is now being noted in Minnesota, where for a long veriod only sporadic cases imported from Scandinavian countries were found. Now, as from Scandinavian countries were found. Now, as Dr. Bracken recently wrote me, there exist three cases of endemic lepers. The so-called Mixed Law of isolation, as practised and so grandly lauded by Dr. Armauer Hansen for his own country, has so singularly failed when practised in both these situations on American soil

American soil.

Third: After the endemic period comes the horrible stage of epidemicity, with all its serious effects for State Government, and people, strangely and always suddenly, without insidious or stealthy approach.

<sup>(</sup>a) Paper read by invitation in the New York Academy of Medicine (Section of Medicine), as a Contribution to the International Discussion on January 19th, 1909.

Hundreds and thousands of victims are found and multiple in families. The types are severer with many mutilating cases. Evidently the virulence of the disease has slowly acquired strength through the endemic period. Contagion, too, would seem to have acquired a voracity for victims through multiplication of the foci, or perhaps by some insect order, or more than one of suctorial pests, has become gradually infected with the germs, and now act as intermediary hosts for the propagation of the disease, by transmitting the spores or bacilli. We conclude, therefore, from the histories of the disease in every climate, and every race, since knowledge of leprosy was acquired, wherever the disease has passed through these three stages, sporadic as it exists now, in New York and our Eastern States, endemic as it already exists in Minnesota, and endemoepidemic as it already presents itself in our negrowhite State, Louisiana:—

First: That the disease respects neither sex, age, nor social condition, and most naturally affects those individuals of any race who are of delicate organisation, or debilitated by wretchedness, privations, excesses, or previous disease.

Sciond: That leprosy spreads itself in all latitudes, and that New York can be no exception to the contagion, no matter what the eminent advisers of our Roard of Health foolishly claim to the contrary, and no matter how prominent and distinguished those dermatologists are in their own speciality, they are not epidemiologists. Leprosy is a science in itself.

We believe also that the disease follows man in all zones, from the frozen regions of Siberia, Greenland, Iccland, and Norway, to the parched districts of India and equatorial Africa. Hence it could not be that those formulated theories which have been specialised in any one place could absolutely be of the same nature everywhere. For instance, that of Jonathan Hutchinson and others about the consumption of fish (as alimentation, not as intermediary host) will not admit of analysis as a sole factor in contagion, in the presence of statistics of this plague in peoples who have never eaten fish, or very sparingly; and in the presence of the further fact that in some places where fish and nothing else was eaten there was never leprosy known until an imported human body had brought the germs. These facts are also really proofs for contagion which Hutchinson strangely persists in refusing to believe in.

Hutchinson strangely persists in refusing to believe in. The one thing which conduces most to the prevalent error about leprosy is that the duration of the latent period is totally undetermined. When and how comes infection? Does anyone know? And who knows whether, before the disease can verify itself, the patient must experience some particular alteration of health? Then only symptoms of invasion known to us as leprosy can present themselves. Who of those stricken can ever know whether, and when and how, in some country infected by leprosy, he has stayed in contact with a leper, has lived in a house once or now occupied by a leper, or touched some things belonging to a leper?

Only continued microscopical examination, made daily of the individual while in such a country, could precisely declare the moment of the invasion of the bacillus of Hansen. Thus it is easily seen how impracticable it is; and, besides, it would be just as difficult as to determine the exact starting-points of the disease throughout the world; to keep in memory all the incidents of one's life that may have taken place everywhere, and of long duration, to keep in view the fixation of the absolute manner and conclusion therefrom as to the predisposing cause of the disease—all this would be little short of impossible unless one devoted his whole life to the work of finding out whether he was becoming a leper or not.

We believe that the disease is naturally infectious—that is, transmissible as malarial fever, yellow fever, cholera, typhoid fever, are, either by direct or indirect methods of contact. We cannot explain its spread anywhere, independent of either hereditary influences, family contagion, contagion fer se, or by some other such circumstances, intermediary host function, or intermediary transmission direct, as determining cause. The theory of heredity (not family contagion) has been rejected by the scientific leprological world. All the

proofs that were ever adduced to support it have actually failed before complete conscientions and scrupulous analysis. Only in Latin America and in some pagar, lands is heredity still believed in.

To-day intra-uterine contagion is accepted. And

there is much reason, without perfect proof, for its truth. It is difficult for anyone to understand, without forgetting the physical law of its impenetrability, the bacillary infection of leprosy as it may unfold itself in the fecundated masculine germ, or feminine ovule. In either case the phenomenon could not verify itself without profoundly altering the organisation of the germ or ovule, in which case there would be no fecundation, and, in consequence, no heredity of leprosy. Or, if there was fecundation, there would he a diseased product of conception, which as yet we have never seen carried to full term in spite of Zambaco's claim to have seen nine cases born leprous. These cases of his are thought by leprologists really to have been syphilitics. Zambaco's refusal to accept belief in non-heredity is considered by leprologists as unsound. It is a fact that children have become leprous soon after birth when created by leprous fathers. But in all such cases it is believed that the intercourse of the father with the mother, after she had conceived, has infected the fœtus through the amniotic fluid; or, where the child was born, when the disease had already appeared in the mother, that it was due to the presence of bacilli in the maternal leprous breast, just as may happen in gonorrhoal infection of the amniotic liquid. I myself saw a child, born totally blind (intra-uterine gonorrheal conjunctivitis), whose father I had treated for gonorrheea when the mother was 51 months pregnant. Intrauterine gonorrheal infection destroyed the sight of this That a leprous seminal fluid, or an infected germinal egg, would produce a viable child, is not believed. Intra-uterine contagion is all that is believed in by leprologists.

It is believed also that the danger of the contagiosity of leprosy increases in direct ratio with the unfolding of the disease—that is to say, that it is more difficult, or less probable, to contract leprosy from a patient who is in the first period of his disease, than from another farther advanced. The mediate, or immediate contact with a leper, is not in itself sufficient to produce the disease in a healthy individual, as follows in all other affections which are eminently contagious.

Heedful, constant and perspicuous observation demonstrates without giving place to the least doubt that for contagion of leprosy to verify itself it is necessary that there co-exist as much for the healthy one as for the diseased one—a real series of conditions on both sides, which may be defined thus: Conditions of transmissibility in the diseased, and conditions of receptivity in the healthy, and which require as indispensable factors not alone some individual circumstances, but those of time, of place, and of manner.

The contagion of leprosy is greater or less, in accordance with the form by which the disease reveals itself, and the period of its unfolding. The mutilating form, for example, is most virulently contagious, when the fingers and toes are eliminating themselves, are about to drop off, or some other parts of the body, show openings, which suppurate and ulcerate, and are terminating their processes of separation. Contagious transmission of leprosy has been attributed by many leprologists to some insects, especially flies and fleas, which may propagate the leprous virus directly on their feet and beaks. To-day there are a number of us who firmly believe that mosquitoes also are vehicles of transmission. I believe that not one insect, but many different species, act as real intermediary hosts, perhaps permit the virus, while they are carrying it, to acquire some peculiarly contagious quality. Carrasquilla affirms to have encountered the bacillus of Hansen in the stomach or intestines of fleas, and infers that some other insects may likewise transmit the disease. I am inclined to believe further than this, that in reality it may be transmitted by the different insects of a country, in different potentialities, if they bite the diseased persons at the different stages of the disease's development or progress, and

afterwards apply their infected organs of suction to the tissues of well persons, which would be equivalent to a real, direct inoculation of the poison. Hallopeau and Montegazza both confirm this belief. The first says :- "It is very probable that the intermediary hosts, and particularly mosquitoes, may habitually serve as propagators of the disease." "We are in accord," says the other, "with those who have given us the evidence of this method of infection." Zambaco Pacha continues obstinately to deny contagion of leprosy. And Virchow, even to the hour of his death, fought against belief in it, as he had previously done at the conference of Berlin in 1897. He declared that "contagiosity of leprosy could not be established as a dogma, until we have found cultivable and inoculable the bacillus of Hansen." In spite of these eminent objections, there prevails to-day, in the science of leprology, a firm belief in contagion of leprosy, both immediate and intermediate. Besnier has graphically defined it in these few words:—"Leprosy comes from lepers, and by no other way, and where there are no lepers there can be no leprosy."

A WORD ON STATE-CURE OF LEPROSY. There are but three methods of State-cure known to science to free a country of epidemic leprosy

(1) Destruction of all lepers by death, or their outcasting absolutely from families. India and Japan have tried this, but because of its imperfect applica-tion it has failed in both countries. The lepers did not die fast enough.

(2) Obligatory segregation (mis-named isolation)—that is, the taking of all lepers away from their families. This has been done successfuly in smaller communities, but is not practised perfectly anywhere

in larger countries.
(3) Deportation of all lepers as fast as they develop

(3) Deportation of an iepers as fast as they develop in families. No State can conquer epidemic or even endemic leprosy except by control of family contagion. Hansen knows this very well. Facultative isolation of lepers only keeps alive family contagion. It really multiplies it. So that only by deportation of his families infected by leprosy, has he so nearly accomplished a State cure for his country. If we should plished a State cure for his country. If we should apply the Mixed Law of Hansen, in this country, as will very likely be advised at the Bergen Conference, we must not only have passed by Congress, a law like that proposed by Senator Perkins, of California, which would deport the lepers from our States to Molokai, but we should also deport those families which prefer to keep their lepers at home. Facultative isolation per se as a State remedy is a farce, unless we adopt also deportation. Obligatory segregation of all lepers is the only safe rule without the practice of wholesale deportation of the infected families.

The present situation of matters here, is as follows: -The number of lepers in the United States, of all nationalities, is far in excess of the number 278, reported by the Marine Hospital Congressional Investigation Committee, of which Dr. White was chairman, under an Act of Congress in 1898. I estimate the whole number to be really about 3,000. Of this number, 400 are Scandinavians, according to Dr. Bracken's estimate. The N.O. Picayune estimated the number of Louisiana's lepers to be 400, of whom only 50 at most are hospitalised near White Castle. It has been estimated that there must be at least 300 Chinese lepers in the United States. This estimate comes to me from Fukien and Quantung Provinces, China. Most of them are employed in washing the linen of Americans, that is, are hidden in laundries. the records of 164 lepers who have been in New York. When the Marine Hospital reported 7 as the number here, I knew of 16. Icelandic lepers are frequent in our North-West States. And Cuban lepers, "mostly rich persons," according to Dr. Robelin, of Havana, freely come and go among us here in New York. In a Colombian boarding-house, down town, I could show you three lepers.

There have been introduced into Congress four leper Bills which have been killed in Committee. Congress having failed utterly, therefore, to help out the situa-tion, as a last resort, I have lately made an appeal, through the Evening Post, of New York, for funds to establish a philanthropic National Leper Asylum. And I have suggested that the Adirondacks be selected

as its site. As our New York Board of Health claims that leprosy is not contagious in this climate, there can be no logical objection made by our people to its establishment there. Or if there is legislative interference, let us put it on some national territory, some place away from the coast. This whole matter might assume a more wholesome aspect, if we could provide assume a more wholesome aspect, it we could provide for its government by a private National Board of Leper Control, fashioned, in a manner, on that of Louisiana, with the objectional features eliminated. A philanthropist might, in fact, appoint his own Board of Leper Control, a member for each State. Or, each State Board of Health could appoint each a member, who collectively would be the "National and the could be the "Varional and the could be the co member, who collectively would be the "National Board of Leper Control of the National Leprosy Asylum." Nothing can be done, however, until we Asymm. Nothing can be done, however, until we find a philanthropist noble enough to take hold of this enterprise. In the course of time (or eternity, perhaps) we may find a way to carry it forward. In the meantime we still will hope that some good may yet come out of our worldly Nazareth.

# OUT-PATIENT'S ROOM.

GUY'S HOSPITAL.

Hernia: Complications after Reduction. By R. P. ROWLANDS, M.S., F.R.C.S.

AMONG the out-patients was a middle-aged man who had had a left inguinal hernia for many years. In the early hours of this morning, Mr. Rowlands said, the patient woke up in pain and found that his supture was lown, and he could not replace it. A doctor was called in, who reduced it without much difficulty, but the patient states he felt a good deal of pain soon afterwards, and that the swelling in the scrotum returned three or four hours later. At present he is cold and blue, and his pulse is quickened (110), and his breathing thoracic and catchy. The temperature is subnormal. He is suffering a great deal of pain in the abdomen, especially in its left side and lower part. He states that the bowels were opened at 8 this morning; he has been sick once since then. The abdomen is distended, and it only moves a little in the upper half; it is very tender in the left iliac fossa, and the irredi cible swelling occupies the left side of the scrotum. This is dull on percussion, except at the upper part, where it is resonant; there is shifting dulness in the flanks; the rectum is empty, and reveals nothing abnormal. With regard to diagnosis, Mr. Rowlands remarked, it is a little uncertain. The main possibilities are:-(1) Return of the hernia, which might have been incompletely reduced; (2) reduction en masse, the band having been reduced through a laceration in the neck of the sac; (3) volvulus of the reduced intestine. The sac reached down to the testicle, so that it could not have been displaced upwards, and therefore the only two kinds of reduction en masse that seemed probable were—(1) by laceration just below the neck of the sac, and (2) displacement into a sac which had gradually formed in the retro-peritoneal tissue as a result of the constant resistance of a truss at the external ring over the inguinal canal. Although the rapid development of very grave symptoms seemed to point to one of these so-called reductions en masse, there were many points against this view. The abdomen was unusually distended for a reduction en masse of such a short duration, and there was an uncommon amount of tenderness and rigidity of the lower half of the abdomen. Moreover, there was no mass to be felt, and no dulness could be made out, both of which are almost invariably to be found in cases of reduction en masse if they are carefully looked for. For the same reasons the return or recurrence of strangulation seemed insufficient to explain these grave symptoms. Moreover, the greater part of the sac was dull on percussion, whereas it should be resonant. The diagnosis of volvulus was supported by the great amount of abdominal distension and the rigidity of the abdomen supervening within a few hours of the first symptom. The fact that the bowels had been opened once was of no consequence, because it only indicated the emptying of the lower bowel below the obstruction. In any case, Mr. Rowlands considered, an immediate exploration was strongly indicated.

The man was at once admitted into the hospital, and Mr. Rowlands explored the hernia. The greater and lower part of the sac contained only blood-stained fluid, but a loop of gangrenous bowel projected into the upper part of the inguinal canal. The lower fibres of the internal oblique and transversalis were divided to give a better view, and, after some difficulty, many coils of gangrenous small intestine were brought down from the left iliac region, and the cause of the obstruc-tion was then revealed. The great omentum had become adherent to the posterior wall of the neck of the sac, forming a strong, thick, irregular band, round which the reduced intestine had become flexed and strangulated. The small intestine had descended on the right and in front of the band, and had been reduced on the left side and behind it. The bowel was greatly distended and black; the constriction was so tight that it had torn the mesentery and ruptured some of the mesenteric vessels; there was a great deal of blood and sanious fluid in the lower part of the abdomen; this no doubt accounted for the dulness in the flanks and for the early signs of peritoneal irri-

Five feet of intestine were resected, and an end-toend anastomosis by direct suture was made. The sac was removed, and the wound sewn up in layers except for a small drain. Directly after the patient returned to the ward a subcutaneous infusion of a pint and a half of saline was given, and ernutin (min. x.) was injected bypodermically every four hours. Nothing was given by the mouth for twelve hours, and then only small sips of water.

The patient was progressing favourable three days after the operation.

# OPERATING THEATRES.

ROYAL FREE HOSPITAL.

FIBRO-CYSTIC DISEASE OF THE TESTICLE.-MR. JOSEPH CUNNING operated on a man, æt. 34, who came to the hospital complaining of a scrotal swelling. enlargement had been noticed for only five weeks, was not painful, but caused a feeling of heaviness, which had called the patient's attention to the swelling. There was no histor, of injury, of syphilis, nor of any previous illness. Mr. Cunning pointed out that the correct way to examine a scrotal swelling was to grasp the neck of the scrotum between the thumb and the index finger: by this means purely scrotal swellings could be differentiated from swellings projecting from the inguinal canal into the scrotum. At the same time any thickening in the vas deferens or other structures of the cord would be discovered. In the present case it was at once demonstrated that the swelling was purely scrotal, and there was no thickening of the vas. The swelling itself was either a tense fluid or a very elastic soft, solid one. On testing it with a light it was discovered to be completely opaque, so that if the contents were fluid it must be a hæmatocele. Hamatoceles, he said, occurred under two different sets of circumstances: the first being a very definite injury, but even then only in a patient, as a rule, who had a long-standing hydrocele; and the second being when a malignant new growth of the testis was present. As there was no history of injury or hydrocele in this case, Mr. Cunning thought that it was of the utmost importance that the scrotal contents should be investi-There was no resemblance to gummatous disease of the testis in this case, for, given the tumour was a soft solid one, it was everywhere of the same consistence, whereas in a tumour which is the result of tentiary syphilitic condition it should be possible to feel the healthy epididymis apart from a round, softer swelling occupying the testis. If the tumour were the result of tuberculous disease it would be possible to demonstrate indurated nodules in the epididymis, possibly soft caseating areas, and probably thickening of the cord as well.

At the operation an incision was made just below the external ring, the scrotal contents being squeezed

up and made to project through the incision. The object of making the incision in this region instead of in the scrotum itself, Mr. Cunning pointed out was that the firm skin could be rendered more certainly surgically clean than the loose scrotal integument, and also that union is much more rapid. On opening the coloured fluid flowed out, but, on enlarging the opening, the cavity was found to be occupied by a large uniform swelling of the testis, with the epididymis thinned and flattened out lying upon it. The tunica albuginea was everywhere smooth, glistening and healthy, and it was impossible to tell by examination whether the consistence was the test of a feather the consistence was the feather the consistence. whether the consistence was that of a soft solid or of fluid, but Mr. Cunning said he must confess he knew of no such fluid tumours which caused a uniform enlargement of the testis, and he felt so strongly that this was a soft, solid growth that he had no hesitation on deciding upon its removal. The testicle, epididymis and cord were then stripped up to the external ring, the vessels of the cord were ligatured separately and the tumour removed. The wound was closed and the tumour removed. The wound was closed without drainage after all bleeding points had been carefully searched for and ligatured; particular attention, he considered, ought to be paid to this point, for a hæmatoma was very apt to occur owing to the loose nature of the scrotum and the difficulty of keeping adequate pressure upon it afterwards.

Mr. Cunning then proceeded to examine the tumour by splitting it. It was then seen that the conditions were as follows:—There was a tumour evidently beginning in the rete testis and expanding the secreting structure of the testis, so that it was spread out as a thin sheet over the growth. The growth itself was a solid fibrous-looking structure with cysts in it, containing clear fluid, and varying in size from that of a pea to that of a bean. In the largest of the cysts seen there were intra-cystic projections. It was clear, then, that the tumour was of that rare kind known as fibrocystic disease of the testis, the pathology of which is still very obscure: it is clearly not of a malignant nature, but if left will certainly cause ulceration in the skin over it, so that the only treatment possible is

excision of the testicle.

The subsequent progress of the case was satisfactory.

# TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

CLINICAL SECTION.

MEETING HELD FRIDAY, MARCH 12TH, 1909.

The President, Sir THOMAS BARLOW, Bart., K.C.V.O., in the Chair.

Mr. James Sherren showed a series of cases illustrating nerve injury from the point of view of treatment.

CASE I .- MUSCULO-SPIRAL PARALYSIS OF UNUSUAL ORIGIN. Male, æt. 26, fractured his left clavicle playing football two and a-half years ago. The arm was put up in Sayre's position with bandages which were removed on one occasion during the month of application, and at this date there was no paralysis. Seven weeks after this he had an operation for mal-union of the clavicle; he said that the nerve was not touched. He had not improved, and did not seem to have had any systematic treatment since he left hospital.

He had come under observation at the London Hospital on March 4th, 1909. All the muscles in the forearm supplied by the musculo-spiral nerve were paralysed, the supinator longus, extensors of the carpus, and fingers and thumb. The triceps was acting nor-There was altered sensibility over the radial area of the hand, but no loss to any form of stimula-The muscles did not react to stimulation with the interrupted current, but reacted well to the constant. With a smaller current than on the sound side they contracted fairly briskly, and there was no polar reversal. The actual cause of injury was uncertain.

The only suggestion put forward was that it was the result of the bandaging, although the exhibitor had never seen the nerve injured in this way before.

CASE 2.—ILLUSTRATING AN UNUSUAL CAUSE OF MUSCULO-

SPIRAL PARALYSIS AND THE LATE RESULT OF NEUROLYSIS.

Male, æt. 23, on March 4th, 1904, caught his left arm between the rollers of a planing machine. When seen four weeks later his only complaint was of altered sensation in the radial area of the hand. At this date there was considerable bruising at the inner side of the arm, and the forearm was held midway between pronation and supination with flexion at the elbow, the wrist being dropped. Pronation, supination, and full extension were impaired. The supinator longus and extensors of the wrist, fingers, and thumb were not acting, but did not give the reaction of degeneration; they failed to respond to the interrupted current, but reacted well to the constant current, though less briskly than on the sound side and to a smaller current, and there was no polar reversal. He was treated by splint and massage for four weeks, but as no improvement took place he was operated upon. An incision to the outer side of the biceps tendon showed that the supinator longus and extensor carpi radialis longior were lacerated and torn from their origins. The nerve was densely embedded in fibrous tissue, but its anatomical continuity was uninterrupted. The muscles were sutured into position and the freed nerve surrounded with oiled silk; the wound was closed and drained by a tube. The oiled silk came away six weeks later. Three and a half months after this operation voluntary power returned to the wrist and fingers, but at this date there was no reaction to the interrupted current. These muscles improved rapidly, but did not react to the interrupted current until six months from the date of operation.

CASE 3 .-- SHOWING THE LATE RESULT OF SECONDARY SUTURE OF THE MUSCULO-SPIRAL NERVE.

Male, æt. 9 (July 28th, 1903), came under observa-tion, at the Poplar Hospital for Accidents, with paralysis of all the muscles of the forearm supplied by the musculo-spiral nerve, these muscles giving the reaction of degeneration. On June 28th he had fractured the lower third of his humerus. This had been reduced by open operation; the paralysis "was noticed several days later.

An operation on August 3rd showed that the nerve had been completely divided with about } in, separation between the ends; the ends were sutured, and the wound healed by first intention.

The first trace of recovery was seen seven months after the suture; the carpal extensors acted voluntarily and reacted to the interrupted current. Three months later (ten months from the date of operation) all the muscles supplied by the nerve acted voluntarily and reacted normally.

CASE 4.—SECONDARY SUTURE OF THE MEDIAN NERVE THREE

MONTHS AFTER DIVISION, SHOWING A STAGE IN RECOVERY.

A male cook, æt. 34, fell from his bicycle July 10th, 1907, and put his hand through a glass window. He immediately went to a hospital and had the skin wound sutured without an anæsthetic. Three months later, light touch was lost over the usual median area, prick could not be felt over the terminal phalanges of the index and middle fingers, and scars of ulcers and blisters, due to his work, were present over the analgesic area. Previous to the nerve section he had not gave the reaction of degeneration.

On October 16th, 1907, operation showed an inch separation between the ends of the nerve; the ends were freed, freshened, and united with fine chromic gut. Recovery had followed the usual stages. Nine months after suture there was no return of motor power or change in the electrical reactions, but anal-gesia had gone, whilst sensation to light touch was returning.

CASE 5 .- ILLUSTRATING THE LATE RESULT OF PRIMARY SUTURE OF THE MEDIAN NERVE AT THE WRIST.

Male, æt. 21 (October 2nd, 1902), cut his right wrist with a knife; he immediately felt numbness in the thumb, index and middle fingers. Primary suture had been performed the following day, and he had been kept under observation and his recovery watched, stage by stage, for four years. Three years after the

date of the primary suture he said that the hand was as well as it was before the accident. When exhibited he did not know any difference from the other hand except in cold weather. It did not interfere at all with his work as a butcher. There was still slight wasting his work as a butcher. There was still slig of the outer group of the thenar muscles.

CASE 6 .- : NJURY OF THE MEDIAN NERVE FROM AN UNUSUAL CAUSE, WITH THE FORMATION OF TROPHIC BLISTERS.

Male, æt. 36, on December 11th, 1908, fell 9 or 10 ft. from a window-sill and hurt his hand, probably by a fall on the outstretched palm. He immediately noticed loss of sensation in the index and middle fingers. Eight weeks ago he put his hand into water, not uncomfortably hot for the sound fingers, and produced blisters on both surfaces of the index and middle fingers and the palmar surface of the terminal phalanx of the thumb. These areas were still insensible to prick and to light touch when examined on February 26th for the first time. The hand was held with the thumb in the median position, with its metacarpal bone somewhat extended and closer to the index finger than normal. The abductor and opponens pollicis muscles were weak but acting. The abductor did not react to the interrupted current, but reacted in a manner typical of incomplete division to the constant. The opponens reacted to the interrupted current. A thickening could be felt in the median nerve immediately above the annular ligament. This case was regarded as an example of injury to the median nerve below the point at which its palmar cutaneous branch is given off. CASE 7.—DIVISION OF THE ULNAR NERVE BELOW ITS DORSAL BRANCH.

Male, æt. 24, sustained an incised wound of the wrist on October 28th, 1908, dividing the ulnar nerve below the point at which its dorsal branch is given off. Primary suture was performed the same day. February 11th, 1909, the loss of sensibility to prick had disappeared, but no change had taken place in the area of loss of light touch, which was as extensive and as well defined as immediately after the accident. All the intrinsic muscles of the hand supplied by the ulnar herve were paralysed and gave the reaction of de-

CASE 8.—COMPLETE SECTION OF THE ANTERIOR PRIMARY
DIVISION OF THE FIFTH CERVICAL NERVE, TOGETHER WITH OR ABOVE THE NERVE TO THE RHOMBOIDS.

On July 31st, 1905, this patient fell off a wall on to some railings, a spike of which penetrated his neck. The wound was sutured the same day at an infirmary, without an anæsthetic. On October 18th. 1905, all the muscles supplied by the fifth cervical rerve were paralysed, and the reaction of degeneration was present in those which could be tested. Loss of was present in those which could be tested. Loss of sensibility was present in the area supplied by the descending branches of the cervical plexus and by the fifth nerve. On October 25th Mr. Hutchinson explored the plexus in the neck. The distal portion of the fifth was united with what appeared to be its central end. The other roots of the plexus were seen to be normal.

When exhibited there was no loss of sensibility, but he showed no sign of motor recovery; all the affected muscles were still paralysed, and give the reaction of degeneration. The deformity resulting from paralysis of the rhomboids was well shown.
CASE 9.—CHRONIC NEURITIS OF THE ULNAR NERVE DUE TO

DEFORMITY IN THE REGION OF THE ELBOW, TREATED BY RESECTION OF THE DAMAGED PORTION OF THE NERVE.

A tailor, æt. 36, showed marked deformity in his left elbow, evidently due to epiphyseal injury in early For seven months before coming under observation in June, 1904, he had noticed weakness of the hand and pain in its ulnar area, increasing in severity and preventing him from following his employment. There were loss of sensation and paralysis in the distribution of the ulnar nerve, and wasting of muscles. The ulnar nerve could be felt enlarged in a spindle-shaped manner behind the internal condyle; it was not manner behind the internal movable laterally to any extent.

On June 17th, 1904, the spindle-shaped swelling was excised, 13 in. of the nerve was removed, and then the rerve was sutured. Recovery followed the usual stages, but was not perfect. The hand was still in the "ulnar" position, with marked wasting of the intrinsic muscles supplied by the ulnar nerve, but they were acting, and he had gone back to work on full wages.

CASE 10.—CHRONIC NEURITIS OF ULNAK NERVE IN THE REGION OF THE ELBOW.

C. W., a carman, æt. 42, came under observation at the London Hospital, February 26th, 1909, on account of wasting of the muscles of the left hand. He had noticed a gradual loss of power in the hand for a year, and for six or seven months the little and ring fingers have been "getting bent up."

The fingers were held in the "ulnar" position; all the muscles supplied by the ulnar nerve were wasted, paralysed, and gave the reaction of degeneration. There was impairment of light touch over the ulnar area of the hand. The ulnar nerve was very prominent behind the internal condyle, and was enlarged in a spindle-shaped manner. Full extension of the elbowjoint was impossible, and there appeared to be some bony thickening beneath the ulnar nerve. X-ray examination showed changes due to osteo-arthritis.

Mr. A. H. Tubby showed three cases of

NERVE GRAFTING. Case 1, that of a patient in whom facial hypoglossal junction had been performed, for division of the facial nerve during the opening of an abscess. Case 2, that of a boy with infantile paralysis, in whom the internal and external popliteal nerves had been grafted. Case 3, that of a man who had been the sub-ject of a total lesion of the right brachial plexus, and consequent fibroneuroma of the fifth cord. This cord

had been grafted into the sixth.

Mr. C. H. FAGGE showed a case of
INFLAMMATORY FACIAL PARALYSIS: TREATED BY FACIAL ACCESSORY ANASTOMOSIS.

Male, æt. 45. Complete left infranuclear facial paralysis had followed an attack of middle-ear suppuration. In December, 1907, the nerve had been exposed and stimulated with non-polarisable electrodes, but as some contraction of the facial muscles had resulted, nothing was done. Electrical treatment had been continued without benefit for three months, so in March, 1908, the facial nerve had been again exposed and divided at its exit from the stylomastoid foramen. It was then found not to be long enough for suture into the hypoglossal without undue tension, so the trapezial portion of the spinal accessory was divided in front of the sternomastoid and an end-to-end union made between it and the distal end of the facial. Electrical treatment was continued and improvement began. Photographs taken six months later show that movements of the left side of the face were best carried out when the left arm was raised.

Mr. C. M. PAGE showed for Mr. Ballance a case of SUTURE OF THE INTERNAL AND POSTERIOR BRANCHES OF THE BRACHIAL PLEXUS.

Female. æt. 21, in July, 1906, had sustained a comminuted fracture-dislocation of the upper end of the humerus, associated with injury to the posterior and internal branches of the brachial plexus. Two months after injury these had been sutured. Recovery of function of the musculo-spiral nerve had followed, and recovery of sensation in the distribution of the

Mr. W. McADAM Eccles showed a case of

CHARCOT'S DISEASE OF THE RIGHT ANKLE-JOINT.

Man, æt. 29, a greengrocer, who denied syphilis and venereal disease, was admitted to hospital with swelling of the right ankle-joint of six months' duration, and a provisional diagnosis of tuberculosis of the joint. But on further investigation it was found that he pre-But on turther investigation it was found that he presented evidence of tabes dorsalis, as shown by the absence of knee-jerks, presence of pupil phenomena, and lightning pains down both lower extremities. The right ankle is completely disorganised, and the skiagram shows extensive alteration of the adjacent articular surfaces of the tibia and astragalus.

Mr. W. R. BATTLE asked whether in consequence of the age of the patient the case was thought to be one

of congenital or acquired syphilis?

Mr. RAYMOND JOHNSON suggested the diagnosis of syringomyelia in view of the presence of lateral cur-

Mr. Eccles, in reply, said that there were no signs of congenital syphilis. There was no dissociation of sensations.

Major C. G. SPENCER, R.A.M.C., showed a case of SARCOMA TREATED BY INJECTIONS OF COLEY'S FLUID.

Male, æt. 33. Admitted in August, 1906, with a large growth in the lower part of the abdominal wall, infiltrating the recti, attached to the pubic symphysis. and extending down in front of the bladder so that it could be felt per rectum. A piece of the tumour had been removed for examination, and was reported to be a spindle-celled sarcoma. An attempt to remove the growth having failed, owing to wide involvment of the peritoneum, injections of Coley's fluid were com-menced on September 22nd, 1906. Since the end of March, 1907, he has not had any further treatment; the tumour has completely disappeared, and he has continued in perfect health.

Mr. WALTER SPENCER said that he had experience of two cases of new growth treated by Coley's fluid. One was a case of sarcoma in the neck, which had been frequently operated upon; the other a case of fibrosarcoma of the sheath of the femoral artery. In both cases the growth had been held in check.

Mr. PEARCE GOULD said that in the Middlesex Hospital cancer wards he thought that most of the cases had not been benefited by this method. It had, however, been tried some time ago, and possibly the fluid had not been quite correctly prepared. He had never had a case comparable to that shown by Major Spencer.

Mr. LAWRIE McGAVIN showed a case of PERINEAL HERNIA.

A widow, æt 36, for two years had complained of dragging pain, resembling a labour pain, in the right iliac fossa, and for nine months had felt a movable "lump" in the abdomen. A swelling in the ischio-rectal fossa had been discovered, which was quite small and easily reducible. Six weeks ago the patient returned with the hernia very much larger, but she did not have any inconvenience referable to implication of the pelvic organs in the hernia. When the mass had been reduced, a gap admitting two fingers can be felt in the central portion of the levator ani muscle, the hernia coming down alongside of the vagina and rectum, through either of which the impulse on coughing could be detected.

Mr. STANLEY BOYD had seen a case which had been diagnosed as one of hernia in the ischio-rectal fossa. This had proved to be fat. He had removed a large quantity, and found that the finger could be put through a hole in the levator ani. He knew of another case of the same nature.

Mr. A. E. BARKER could recall a case like that shown. He doubted whether it was a hernia, but considered it more probably a lipoma.

Mr. H. Goodwin showed a case of

"BUTCHER'S STREPTOCOCCUS."

The wife of a butcher scratched the terminal phalanx of her index finger. Four days later the finger became erythematous and cedematous; the next day the condition had spread to the wrist, and there was much cedema of the dorsum of the hand. Incision of the swelling gave exit to sanious serum containing streptococci, and next day the condition appeared cured. Five days later a patch of erythema with an œdematous margin returned; cultivation showed a streptococcus, and the patient was treated with a vaccine in doses increasing up to 1,000 million. The patches, however, gradually spread until the whole chest was covered after an interval, during which the condition appeared to be arrested, it appeared on the ankle, and has spread above the knee. Bier's method was employed, but vaccine treatment was not tried again. In November the discharge was sterile. The application of Xrays for ten minutes twice a week has appeared to do good, but the patches continue to spread.

Dr. OFENHEIM showed three cases of

SEPTICÆMIA TREATED BY VACCINE THERAPY.

Case 1, Nurse S., finger was infected from a case of otitis media. Whitlow in left thumb on February 20th, 1908, and or. March 5th general septicæmia had followed. Several incisions were made. Cultures from the pus yielded staphylococcus aureus and streptococcus pyogenes, and cultures from the blood showed S. pyogenes in pure culture. From the latter a vaccine

was made and inoculations given under constant con-

trol of the opsonic index.

Case 2, Mrs. X., was delivered of a stillborn child on January 27th, 1908, after version for placenta prævia. Admitted to hospital on February 5th with rigors, sickness, diarrhoea, and profuse vaginal discharge. Temperature from 101° to 103° F., pulse 110-112. On February 10th cultures from the vaginal discharge and from the blood were taken. The former grew S. pyogenes and a few colonies of bacillus coli communis; the latter grew S. pyogenes in pure culture. On February 18th patient received the first inoculation from her own vaccine. The patient was discharged quite well on March 12th.

Case 3, male, admitted on March 18th, 1908, with supposed enteric fever, after having been bitten by a rat on the left thumb five weeks previously. He had a few rigors, headache, dry furred tongue, an erythematous rash, and a temperature varying between 99° and 104° F. On March 29th cultures taken from some erythematous patches, after scratching the skin, grew micrococcus tetragenus. A vaccine was made from this organism, but the patient did not show any improvement after two inoculations. Indices could not be taken, because his serum agglutinated blood-corpuscles at once, even in dilutions of 1 in 60, and the agglutination test was negative. On March 24th a blood-culture again grew the same organism, whilst previous blood-culture had remained sterile. Inoculations were resumed, and given until July 6th, from which day patient was in perfect health. M. tetragenus frequently co-exists with tubercle bacilli in pulmonary tuberculosis as a non-pathogenic organism. About 42 cases are on record in foreign literature in which M. tetragenus showed pathogenic action. It is frequently found in rats and mice, producing septicæmia in these rodents.

Dr. H. D. ROLLESTON showed a case of LYMPHADENOMA WITH VARYING JAUNDICE.

Girl, æt. 7, had enlarged glands on both sides of the neck and in both axillæ; one of the glands had been excised and showed the histological appearance of lymphadenoma. The liver and spleen were enlarged. At irregular intervals of from a week to a fortnight the patient had febrile attacks, with increase in size of the glands and liver and very definite jaundice. Presumably the jaundice was due to pressure exerted by lymphadenomatous intra-abdominal glands on the bile-duct, probably in the portal fissure, as no enlargement of the gall-bladder had been detected. Between the febrile attacks the jaundice diminished, but now did not disappear.

did not disappear.
Dr. A. E. Wynter showed a case of PULMONARY STENOSIS.

Female, at. 16, had rheumatism at 12 years of age, and occasional sharp pain in left submammary region during the past four years. She became dyspnœic on exertion and swelling of the face and abdomen was said to have occurred at times. A systolic murmur was audible at the left third chondro-sternal junction, and was conducted upwards towards the left clavicle. The superficial cardiac dulness was only slightly increased to the right apex beat in normal position. Complexion was pale with crimson lips.

Dr. A. E. Wynter also showed a case of INFANTILE PARALYSIS: PARAPLEGIC DISTRIBUTION WITH INVOLVEMENT OF ABDOMINAL MUSCLES ON THE LEFT SIDE.

Male, aged 6 months, breast-fed. No previous illness. Shortly after a fall on December 5th, 1908, the patient had a fit and was soon after observed to be paralysed. Protrusion of the left side of the abdomen was noticed about December 18th. He was admitted to Middlesex Hospital, January 30th, 1909.

Dr. A. E. Wynter also showed a case of CURE OF ASCITES BY PERMANENT DRAINAGE THROUGH THE

FEMORAL RING.

Male, æt. 50, was admitted on September 14th, 1908, for ascites associated with hepatic cirrhosis. For six weeks attempts were made to reduce the ascites by drugs. It was then found necessary to remove the fluid by paracentesis, but it recurred within a fortnight. In the middle of November Mr. J. Murray opened the femoral canal, inserting a decalcified bone tube, and fluid continued to drain away for three weeks. Since the healing of the incision the patient

had been getting about, and there has been no further need for paracentesis.

Dr. A. E. GARROD read a short paper on a case of URÆMIA OR MENINGITIS.

It was that of a boy who had been admitted to the Hospital for Sick Children, Great Ormond Street, because he had been passing black urine. There was no history of a decreased quantity of urine being passed. When seen on admission, he lay curled up, and resented disturbance. He spoke, if questioned, but was occasionally incoherent. He was pale and emaciated. The pulse-tension was equal to 125 m.m. of mercury. The urine contained blood and a dense cloud of albumin. About 325 c.c. were passed in the first 24 hours. Granular and blood casts were present. There was considerable general tenderness. The abdomen was retracted. The knee-jerks were increased, and ankle-jerk was obtainable on the right side. The left plantar response was extensive, the right was not obtained. Kernig's sign was present on both sides. No optic neuritis was present.

The next day the head was retracted, there was active delirium, and the boy was incontinent. Treatment was started as for uræmia. Varying rigidity—lasted until the 8th day, when improvement started and continued until complete recovery ensued. For a few days the amount of urine was considerably diminished. With recovery the albumin gradually lessened and finally disappeared altogether from the urine. A lumbar puncture had been unsuccessful in

obtaining fluid.

He thought the case was one either of meningitis or uræmia. If meningitis, it was probably meningo-coccal in origin. Koplik had described nephritis as occurring in that disease. If meningitis, it must have been very slight, and the rapidity of the convalescence was unusual. In favour of uræmia, cases had been described in which symptoms like meningitis had occurred, but in these the convalsions had been clonic, not tonic. Weiss had recorded two cases diagnosed as tuberculous basic meningitis which proved to be chronic interstitial nephritis.

Dr. PARKES WEBER asked whether he had noticed that tapping the muscles led to an extreme degree of muscular contraction? He had had a case of extraordinarily exaggerated tendon reflexes preceding uramic

oma.

Dr. H. D. ROLLESTON suggested that possibly this case might be influenzal. The kidneys were occasionally considerably affected in that disease.

Dr. G. A. SUTHERLAND said that similar symptoms occurred in middle-ear disease. He agreed with Dr. Garrod that uræmia was the most probable diagnosis. He compared these symptoms to those sometimes seen in cases of pneumonia.

The PRESIDENT said that a combination of hæmorrhagic nephritis and cerebral symptoms occurred sometimes in acute diseases, and the prognosis in such cases was not always bad. It was also true that exactly such symptoms were seen with otitis media. In uræmia, where there was much rigidity and irritability, and where convulsions were present, he found that the absence of Babinski's sign was of great value.

symptoms were seen with otitis media. In uræmia, where there was much rigidity and irritability, and where convulsions were present, he found that the absence of Babinski's sign was of great value.

Dr. Garron, in reply, said that he had not noticed any particular effect by tapping the muscles. It was highly probable that the case was one of acute infection, but there was no particular indication that it was due to influenza; moreover, black urine was passed long before the child was acutely ill. Examination of the ears had revealed no abnormality. He had often noticed earlier recovery in cases of nephritis when the blood passed was proportionately greater than the albumin.

Dr. Macnaughton-Jones read a paper on

CANCEROUS TUMOUR OF THE SPINAL MENINGES, INVADING
THE CORD AND CAUSING PARAPLEGIA, SECONDARY 50
MAMMARY CARCINOMA.

At the last meeting of the Departmental Committee of the Privy Council to inquire into the working of the Midwives Act, evidence was given by Dr. A. Robinson, Medical Officer of Health for Rotherham: Sir George Fordham, Treasurer of the Central Midwives Board; and Mrs. Heywood Johnstone. President of the Rural Midwives' Association.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD MARCH 3RD, 1909.

The President, Dr. JAMES RITCHIE, in the Chair.

MR. J. W. DOWDEN showed: (1) A man on whom he epithelioma of the lip. The glands were thoroughly cleared out 10 days after the tumour was excised. There had been no recurrence. It was advisable to perform such operations in two stages, in order to lessen the risk of lymphatic infection in removing the cancer. (2) A patient, nine months after interscapulo-thoracic amputation for recurrent sarcoma of the deltoid.

Mr. ALEXIS THOMSON showed (1) two cases of internal derangement of the knee-joint. It was not possible, except in typical cases of displacement of the anterior end of the semi-lunar cartilage, to say beforehand what the exact cause of locking was, hence it had been necessary to open the joint freely by transverse division of the ligamentum patellæ. In one case the posterior end of the internal semi-lunar cartilage was found to be thickened and frayed; in the other a tag of cartilage depended from one of the crural ligaments. In both patients good power of extension was present, although the ligamentum patellæ had been divided. (2) A girl who, as the result of an extensive burn in childhood, had acquired an extreme degree of flexion contracture at the elbow and wrist. This had been relieved by resection of both the elbow and wrist-joint, and by the grafting in the flexion aspect of each joint of a flap taken from the anterior abdominal wall.

Dr. EDWIN BRAMWELL read a paper on THE PROBLEM OF THE SANE EPILEPTIC.

His object in bringing the question before the Society was to arouse interest in the matter, because in Scotland there was no provision made for such patients. He did not think there was any ground for supposing that epilepsy was less frequent in Scotland than in England. During six years he had collected notes of over 70 cases at the Leith Hospital out-patient department, out of a population of about 80,000. He pointed out that epilepsy hampered patients as children in relation to education, and as adults in relation to work. Many of the cases he saw were comparatively well in the intervals, and yet, on account of the disease, they had the greatest difficulty in getting work. The difficulty was greater now than formerly on account of the operation of the Workmen's Compensation Act. He described the working of the epileptic colony, which he regarded as fulfilling the needs of these patients better than any other method of institutional treatment. In Scotland a small epileptic colony had been started by the late Mr. Quarrier, but, with this exception, the country had been extremely backward in dealing with

this class of the community.

Dr. Dunlor thought that epileptics should be under the care of the lunacy authorities, and objected to colonies on the ground that insane epileptics tended to accumulate there, and to escape the supervision of the Lunacy Commissioners. He regarded so-called "sane epileptics" as forming a small percentage of the whole, and thought that they should be dealt with under the Poor-law

Dr. Byrom Bramwell, and several other speakers supported the view that epileptic colonies should be provided, and it was pointed out that Dr. Dunlop's criticism was directed against the administration, not against the principle. Proper medical examination and transference of patients to asylums as soon as mental deterioration set in would prevent colonies becoming unlicensed asylums.

Mr. ALEXIS THOMSON read a paper on

THE DIAGNOSIS AND TREATMENT OF CHRONIC ULCER OF THE STOMACH AND DUODENUM,

which will be found on page 263 of our present issue. Professor Caird, Mr. C. W. Cathcart, and others discussed Mr. Thomson's paper.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY

MEETING HELD FRIDAY, FEBRUARY 19TH, 1909.

Mr. SETON F. PRINGLE in the Chair.

ŒSOPHAGEAL DIVERTICULUM.

MR. WILLIAM TAYLOR read the notes of a case of œsophageal diverticulum, which he had removed from a gentleman in June, 1908. The patient was fifty-four years of age, and his symptoms dated back for about twenty years. The symptoms had been gradually getting worse. Food was usually regurgitated into the mouth just as it had been eaten, sometimes almost immediately, at other times after several hours. Not immediately, at other times after several nours. Not unfrequently portion of the previous night's supper was regurgitated next morning while in the bath. Pills taken at night were frequently regurgitated unchanged next morning. A feeling of fullness and discomfort after eating was generally referred by the patient to the right side of the neck, about the level of the hyoid bone. Attempts to pass bougies failed their passage being arrested about nine inches from the teeth, but their passage seemed to be arrested more from spasm of the œsophagus than from encountering any other source of obstruction. There was no swelling to be detected on inspection of the neck. [A beautiful radiogram of the pouch filled with bismuth food was taken by Dr. Watson and shown at the meeting, as well as the pouch itself. Through the "screen" before the photo was taken each bolus of food the patient attempted to swallow was seen passing into the pouch.] The pouch took its origin from the left side of the esophagus just at its junction with the pharynx, and passed downwards behind the esophagus, to terminate at a point just below the supra-sternal notch. The diverticulum was removed through an incision extending from the hyoid bone along the anterior border of the left sternomastoid muscle to the sterno-clavicular articulation. The anterior belly of the omohyoid muscle and the superior thyroid vessels were divided. The lateral lobe of the thyroid gland, which was considerably enlarged, was displaced, after which the diverticulum was readily seen and withdrawn, there being no adhesions. Two small intestinal clamps were applied, and the diverticulum removed by dividing between them. The opening into the esophagus was closed by three rows of fine silk sutures. A small tube was passed from the centure of the wound in the neck down to the region of the sutured œsophagus, and a piece of gauze loosely packed around it. About three-quarters of the neck-wound was closed. The wound healed by first intention, unless where the drainage had been applied, but even that was healed up by the end of twelve days. There was never at any time any sign of leakage from the œsophagus. Nourishment by the mouth was withheld for four days. Rectal salines, with raw meat juice, were administered every six hours. Nourishment was given by the mouth on the eighth day, and gradually increased in amount and in consistency until a lamb chop was easily partaken of on the sixteenth day. The patient is now in perfect health, and has no difficulty in swallowing.

Mr. Taylor then briefly discussed the literature of

the subject.

The CHAIRMAN said the case was one of the first, if not the first, of such cases reported to the Academy. He wished to know if the œsophagus had been examined since with the bougie, and if the spasm had disappeared.

Dr. MAGEE FINNY said the patient was under his observation for some years, and as far back as 1903 it was thought he had something of a pouch about his throat. It was a great worry to him, and seemed reflexly to produce nervous irritation and dyspeptic phenomena. One could not forecast how long it would be safe to allow a patient who had a diverticulum to go without operation. It was interesting how the diverticulum could swell out and prevent a tube passing, and yet did not prevent the tal g of food and drink. At his suggestion, Dr. Watson tried a meal of bread and milk for making a radiograph, and obtained excellent results. The same method had been tried on a patient approaching eighty years of age, and the radiograph which he exhibited showed a pouch corresponding to that in the former case. A later picture showed a lateral increase, and he would have another one taken shortly. They gave this patient the same mixture as Mr. Taylor used, and they could see it on the screen catching in the pouch and slipping down.

Dr. M'VITTIE referred to a case of dilatation of the cesophagus, brought about by spasm, in which the patient was dying of starvation. By the use of Russell's œsophageal stricture dilator, which he

exhibited, the patient was completely cured.

Mr. L. G. Gunn said he had a case which seemed an ordinary case of carcinoma of the œsophagus. He did a gastrostomy, and did not think the patient would live long. Thirteen months afterwards he saw him again, looking well, and having put on weight He then thought he had a diverticulum obstructing the gullet. Dr. Woods examined the case with the œsophagoscope, and snipped away a small portion of the stricture, which proved to be a carcinoma.

Mr. R. A. STONEY mentioned a case in which the diagnosis lay between malignant disease and some simple stricture of a syphilitic nature. He opened the stomach, which was small and adherent, and fed with a tube from the mouth to the stomach. Later he had to do a duodenostomy, and lost sight of the

Mr. TAYLOR, in reply, said he had not passed a bougie since the operation was done. The condition was not usually noticed until a surgeon questioned the patient, when it was not unfrequently found that the symptoms began about thirty to forty years of age. His patient dated his symptoms back twenty years. Esophageal pouches of a pressure type were met with always at the junction of the pharynx and œsophagus, and he was convinced that, unless in extreme cases, the shadows in a radiograph would not extend below the pericardium.

SUPRA-PUBIC PROSTATECTOMY.

Mr. L. G. Gunn read a paper on complications following on supra-pubic prostatectomy. He detailed his experience of the operation, and mentioned especially as complications fistula, impotence, persistent cystitis, formation of stone, persistence of some frequency of micturition, impaired power of the

requency of micturition, impaired power of the compressor urethræ muscle, and anæmia. The Chairman recalled a troublesome case of fistula, and thought it was not wise to tie in the catheter. A fistula would close rapidly, but as soon as the catheter was taken out the scar tissue would re-contract. For a few days after operation he generally used suction apparatus. He had come to look on hiccough in a prostatectomy case as a sure precursor of death.

precursor of death.

Mr. Wm. TAYLOR said he had recently been thinking whether they were not foolish in sticking to the suprapubic method, and not removing the prostate by the perineal route. Mr. Young's statistics showed 110 cases done in succession without a single death, and in 146 cases there was only one death. His own mortality was 8 per cent. to 10 per cent. He looked on the use of scissors as more or less unsurgical even on the use of scissors as more or less unsurgical even under one's eye, and to use them blindly did not appeal to him. Among the complications following the operation he had seen senile gangrene arising, he believed, from a weak heart. He had also seen pelvic cellulitis follow, and he had seen a patient die apparently of hæmorrhage and shock. He had found that cases in which he did not use suction apparatus that cases in which he did not use suction apparatus did as satisfactorily as the ones in which suction was required. He now used nothing but a pad of wool, and the results were satisfactory. He looked on hiccough as a sign of uræmia, and consequently a

fatal sign.

Mr. Gunn, in reply, said the less appliances they had the better. He thought it was hardly fair to take the statistics of one man, who was an expert at an operation, and selected his cases carefully. American statistics were not as good as the general English statistics, and impotence and troubles of a similar kind must be more frequent after the perineal than after the supra-pubic operation. He thought it was better surgery to pass a curved scissors and cut through the sutures than to drag them with the finger. In two cases of Bottimi's operation which he had seen the results were completely satisfactory.

# WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD MARCH 5TH, 1909.

The President, Colonel T. H. HENDLEY, in the Chair.

DR. E. FURNISS POTTER read a paper, illustrated by lantern slides, on

THE SUBMUCOUS RESECTION OPERATION FOR THE REMOVAL OF DEVIATIONS AND OBSTRUCTIVE DEFORMITIES OF THE NASAL SEPTUM.

Dr. Potter showed that what were formerly regarded as purely ledge-like outgrowths of bone or cartilage, are in reality the thickened angular summits of septal deflections, hence the sawing off of the obstructing spur was frequently disappointing as only a small shaving of cartilage was removed, or else a large perforation made.

Dr. Potter described the operation:—Position.—
Patient lying down, face towards operator. Anastatic: Local.—Plugs of 20 per cent. novocain, with an equal part of 1 in 1,000 adrenalin, placed in each nostril and left in for 30 to 45 minutes. Illumination.—Focal head electric light. Operation.—(1) Vertical incision on the convex side of the deviation in forms. cision on the convex side of the deviation, in front of the deviated portion made from as high a spot as possible through the mucous membrane and carried down to the nasal floor. (2) Mucosa with the perichon-drium deflected from cartilage with an elevator. (3) Vertical cut through the cartilage anterior to portion Vertical cut through the cartilage anterior to portion to be resected. (4) Elevator passed through the slit in cartilage and mucous membrane, cautiously reflected from the concave side. (5) The whole of the mucous membrane being thus reflected from both sides of the cartilage, the cartilage is now removed either with a special swivel knife or punch forceps. and the incisor crest by Killian's gouge (6) If properly performed, the two mucous membranes should hang straight in the middle line of the nose. and each nostril should be plugged with well-vaselined pieces of cotton wool, which may be removed after 24—48 hours, and daily gentle irrigation with alkaline lotion is all the after-treatment required.

Dr. Potter, in conclusion, claimed the following advantages:—(1) The establishment of a free nasal passage attained with certainty. (2) No general anæsthetic required. (3) Rapid healing, no splints or drainage needed. (4) No loss of mucous membrane.

Dr. Wyllie expressed himself as in favour of the intition and the interior.

sitting-up position, and of stitching up the incision

with a special fish-hook-like needle.

with a special fish-hook-like needle.

Dr. Barry Ball reviewed the history of the operation, and emphasised the caution of Dr. Potter's as to the necessity of leaving at least 5 mm. of cartilage beneath the bridge of the nose, lest sinking in of the bridge should take place.

Dr. Davis preferred general anæsthesia to local.

Dr. ASLETT BALDWIN asked whether there was not a leave of the property of the property

danger of a sail-like flapping septum resulting from the operation.

Mr. RICHARD LAKE agreed with Dr. Potter as to the unimportance of celerity as opposed to thoroughness in

the operation?

Mr. Bowen pointed out the importance of firm nasal plugs in preventing the formation of blood-clot between the two mucous surfaces.

Dr. FURNISS POTTER, in replying, did not agree with Dr. Wyllie that the sitting position was the best; had used the special needle, and had abandoned its use: was unable to accept Dr. Davis' suggestion as to general anæsthesia; agreed with Dr. Ball that the operation was not possible before the adrenalin era; and, in reply to Dr. Baldwin, stated the operation resulted in a hard and rigid septum, satisfactory in every way.

## ULSTER MEDICAL SOCIETY.

MEETING HELD ON THURSDAY, MARCH 11TH.

The President, Mr. T. S. KIRK, in the Chair.

Professor Sinclair opened an adjourned discussion on gastric ulcer. He expressed himself strongly in favour of gastro-enterostomy as against excision of ulcers, and was quite satisfied with the results he

had obtained in operating on about 80 cases of ulcer.

Mr. A. B. MITCHELLadvocated again the infolding
of gastric ulcers, an operation which he had originally suggested, and which he still believed to be the best method of dealing with this trouble.

Mr. Robert Campbell drew attention to the fact that one often opened the abdomen and failed to find

on the outside of the stomach any sign of ulceration.

Dr. John MacIlwaine discussed the etiology of the affection. From his experience as Medical Registrar at the Royal Victoria Hospital, he believed in the very close association of anæmia, hyper-acidity of the stomach, and gastric ulcer. He thought there was stomach, and gastric ulcer. He thought there was often great difficulty in deciding into which of these three classes certain cases should be put.

Sir John Byers drew attention to the fact that the ultimate result of gastro-enterostomy for gastric ulcer was often most disappointing. He deprecated promiscuous surgical interference.

Mr. FULLERTON said that he believed in the septic origin of many cases of ulcer. He thought that a trial should be made of excision of the ulcer before a

gastro-enterostomy was advised.

Mr. Howard Stevenson drew attention to the importance which physiologists attach to the passage of food through the duodenum in stimulating pancreatic secretion.

The President insisted that in cases where a laparotomy was done, and no sign of ulcer was seen on the surface of the stomach, the stomach should always be opened and examined. Many of the cases which simulated ulcer were really cases of contraction of the pylorus, and gave better results from stretching of the pylorus than from gastro-enterostomy. This was the class of case where gastro-enterostomy gave such un-

satisfactory results.

Dr. CALWELL, who had opened the discussion at the previous meeting, replied to a number of questions put by previous speakers, and wound up a most

interesting discussion.

A resolution forwarded by the Irish Medical Association (Fermanagh Branch) ,and which has already been printed, was discussed at length. It was finally agreed that, while it was desirable that regular paid health lecturers should be appointed by the authorities, the time was not ripe to insist on pioneer work in health matters being confined to paid officials.

## CORRESPONDENCE.

# FROM OUR SPECIAL CORRESPONDENTS ABROAD.

## FRANCE.

Paris, March 14th, 1909.

TREATMENT OF ANTHRAX

TOTAL extirpation of anthrax had been proposed years ago by Broca and Tielal, and practised once or twice by Labbé and then forgotten. Recently, how-ever, Dr. Mabbini, of Marseilles, reported two cases of extensive anthrax operated on by him with complete

The first patient, suffering from diabetes, presented a voluminous anthrax in the back. Dr. Mabbini removed it completely, and at the end of a month the

wound had entirely healed.

The second patient entered the hospital for a large arithms on the back of the neck. No glycosuria was present. The anthrax was removed under the influence of local anæsthesia by chloride of methyl, and the patient made a rapid recovery. Where the tumour is very extensive, general anæsthesia should be used.

Extirpation, which is completed in three or four minutes, should include not only the diseased parts, but also a small portion of the healthy tissue, the incision being made about a quarter of an inch outside the limit of the anthrax.

A compressive dressing is generally sufficient to arrest the bleeding, but, if necessary, one or two ligatures might be applied. A dressing of oxygen water is renewed every day.

When the granulations attain the level of the surrounding skin-that is to say, in ten days-cicatrisation may be stimulated by touching the parts with natrate of silver or practising grafting, according to the method of Ollier-Thiersen.

The great advantage, observes Dr. Mabbini, of the method, is to bring about a fall of the temperature when it exists, and to arrest the general symptoms, as a wound, eminently septic, has been transformed into a normal wound, which will heal normally, and from which all fear of infection is removed—a fact of no mean importance in cases of diabetic patients.

The classical method of incision followed by Spaay is tedious, and the persistence of a septic wound might produce phenomena of resorption frequently mortal. Further, the healing process requires from four to six weeks, whereas by the method of extirpation the dura-

tion does not exceed 25 days. TREATMENT OF HEMATEMESIS.

The treatment of hæmorrhage of the stomach comprises delicate and complex indications. The gravity of the immediate accidents and the tendency to col-lapse, renders necessary very energetic treatment. On the other hand, the necessity of complete rest of the stomach is an obstacle to the administration of the drugs usual in such cases. Yet absolute rest is nevertheless a fundamental condition for the arrest of the hæmorrhage.

Rest in bed is consequently the first condition, with the head low and the legs drawn up, motion or speaking forbidden, while all solid or liquid food is suppressed for three or four days, after which nutritive enemas might be given, and if the thirst is not suffi-ciently relieved, a few injections of artificial serum are administered, or the patient allowed to suck pieces of ice. When the patient or those around him revolt against this continued abstension, a little iced milk or cold beef tea might be allowed.

As to the application of ice externally, Dr. Plicque, who is an authority on gastric affections, considers that if it is useful in average cases, and especially where the hæmorrhage has a tendency to repetition, the local application of ice where patients are very weakened by the abundance of the hæmorrhage in-

creases the tendency to collapse.

MM. Tripier and Bouvert recommend a directly opposite method to produce vaso-constriction. They employ enemas of hot water (104° F.), which act both on the hæmorrhage and the fainting condition. The method renders great service in grave cases, and especially when ice cannot be had. The enemas are given twice a day for two or three days, and then once a day for several subsequent days. In extremely grave cases ligatures might be placed at the root of the limbs. They are not only useful against the hæmorrhage, but also diminish the sensation of fainting so frequently experienced.

As to drugs, ergotin or its alkaloid, given in subcutaneous injections, are the most frequently employed.

Adrenalin is best given by the mouth:—

Sol. of adrenalin, 12 drops.

Water, 2 oz.

A teaspoonful every five minutes for four or five doses, afterwards every ten minutes.

Injections of morphia are very useful, as they relieve the pain and burning sensation which accompany hæmatemesis.

Numerous other drugs are employed against gastric hæmorrhage; perchloride of iron, ferropyrin, antipyrin, ergot of rye associated with opium, subnitrate of bismuth, chloride of calcium, or chlorate of soda (cancer).

As to a surgical operation, Dr. Picque believes that if theoretically it can be justified, practically, it gives poor results. In such cases, either the hæmorrhage has ceased or the patient has succumbed before surgical aid is at hand.

As soon as immediate danger is averted, attention should be turned to the cause of the hæmorrhage, ulcer, cancer, atrophy of the liver (varicose veins of the œsophagus), and should be treated accordingly.

THE RATIONAL TREATMENT OF CEREBRO-SPINAL

MENINGITIS.

As soon as vomiting, headache, stiffness of the neck, and the Kernig sign are observed, lumbar puncture should be performed. If pus issues, an ounce and a half should be drawn off and replaced by an injection of an ounce of antimeningitic serum of Wassermann or Dopter. The operation should be renewed for three or four days in succession, or until a complete cure, which occurs in 70 per cent. of the most favourable

GERMANY. Berlin, March 14th, 1909

HYPERNEPHROMA OF KIDNEY.

At the Medical Society, Hr. W. Levy showed a kidney that contained in the upper pole a hypernephroma. The patient was first attacked with hæmorrhage from the kidney in August, 1907, from that time for nearly a year it occasionally returned. could be felt over the kidney. By the cystoscope blood was seen coming from the left ureter. No shadow of a stone was seen by Röntgen illumination; tubercle bacilli was not found in the urine, and test inoculation also had a negative result. As the patient, however, had some attacks of renal colic in January last, he consented to undergo an operation, took place on the third day from collapse.

A second preparation shown was a pylorus removed for carcinoma. The patient was a man, æt. 54. Although the man was fat, and the abdominal walls were tense, a tumour could be felt sufficiently distinctly. The tumour was removed completely, the sections being made through parts that were healthy. He died some weeks later from cerebral symptoms; which were supposed to be due to a fracture of the skull that had

taken place a short time before.

Hr. Orth communicated some details regarding a

NEEDLE SWALLOWER,

obtained at the autopsy on an elderly unmarried woman. The woman had spent 18 years of her life in the poor-house at Colber, and there she showed a passion for inserting sewing needles under the skin, a large number of which were removed during the course of years. Some months ago an abscess formed in the neck, which opened and led to the formation of a fistula; at the same time difficulty of breathing came on. In the Röntgen figure eight reedles were seen at the base of the tongue, lying in various directions. On account of the bad general condition of the patient, no attempt was made at removal. She died shortly afterwards of pulmonary phthisis. The autopsy revealed numbers of needles in the skin as well as in the internal organs, and one in each of the following: the liver, the mesocolon, the throat, the right heart, and in the aorta. The speaker considered that the needles, which were found mostly in the organs of digestion, were swallowed, and this was afterwards found to have been the case. Except in the throat, no pathological changes were observed in the parts where the needles lay; the most remarkable thing was that no changes appeared to have been caused by the needle in the aorta except at one spot, where it had become slightly rusty, and where there was a small thrombotic deposit, and this notwithstanding the fact that the needle had penetrated transversely through the whole thickness of the vessel, and remained in that position. This confirmed in the human subject what had been stated in respect to animals by Eberth and Schimmelbusch-viz., that foreign bodies only caused clotting in blood vessels when they presented a roughened surface; fine threads became covered by thrombi, but smooth glass needles did not.

Hr. v. Hansemann showed 704 foreign bodies, nails, needles, and the like that had been found in the stomach of a girl who had tried to commit suicide, and, as this had not been successful, had taken

phosphorus. Not the slightest trace of injury was found in the walls of the stomach, except for a perforation; and such were only to be met with at the cardia, or the pylorus, or in the intestine, as in these spots the walls in contracting thrust aside the soft contents.

Hr. Senator had seen a piece of glass that had worked its way from the stomach by suppuration; it must therefore have penetrated the stomach wall.

At the Surgical Society Hr. Busch showed three cases

of obstruction of the bowels. One was a case of strangulation from a band. The bowel, which was not free from suspicion, was drained by a tube, the abdominal wall suppurated, and a fæcal fistula resulted, and a large piece of small intestine, with mesentery, protruded through the opening; the anus præternaturalis that had formed in this way had to be closed, but recovery finally took place. The second was a case of invagination in a child, four years of age; the invaginated portion could be withdrawn; on its base was a Meckel's diverticulum, which was removed; pancreatic tissue was present in the walls. The third was a case of ileus caused by a Meckel's diverticulum.

## AUSTRIA.

Vienna, March 14th, 1909.

Asthma.

HOFBAUER presented four cases of asthma bronchiala whom he had treated successfully by a method he described to the members of the Gesellschaft der Aerzte two years ago. These cases, he said, had stubbornly resisted the usual methods adopted of rubbing in iodine, giving potassium iodide, atropine, morphia, etc., but with no benefit or relief to the patients. He therefore resolved to apply his gymnastic respiration, with immediate relief. The treatment patients. He therefore resolved to apply his gymnastic respiration, with immediate relief. The treatment consists in teaching the patient to take long expirations, to avoid waste of energy, and making the inspirations as short as possible. To this treatment he adds electric currents, which the patient uses at his own home. The latter is used only intermittently, but the fined mental principle of the treatment is the long the fundamental principle of the treatment is the long expirations and short inspirations, which require some practice and patience in those suffering from the disease. From the description given of these cases the results appear to be excellent. HYPERHYDROSIS.

Freund brought forward a young man who had come into hospital complaining of a severe form of hyper-hydrosis manum of the hand, which was success-fully treated by means of the Röntgen rays. This patient had both hands greatly enlarged and several of the fingers deformed. From the symmetry of the contractions at the phalangeal articulations, he concluded tractions at the phalangeal articulations, he concluded the deformity was congenital. Both of the little fingers were fixed at an angle of 120°, which could not be moved actively or passively. Extension could not be relieved by operation on the interphalangeal joints and dividing of the palmar aponeurosis. By closer examination the extension of the fingers were held by bands on both sides of the joint, which appear to have existed from childhood. The mother had also one hand with a little finger in a similar position, which favours the opinion of heredity. Schlesinger said he had seen several families suffering from the same contractions in the little fingers, but none of them had been so well marked as in this case.

TRAUMATIC NEUROSIS.

Benedikt presented a patient who in June, 1897, had a severe injury to the head, which left him suffering for a few days after from the symptoms of shock. About the middle of October slight hemiparesis of the right side, with all the appearance of traumatic neurosis commenced. The disease gradually green the research of the second property of the second part of the s worse up to 1900, when a series of epileptic fits commenced, with short periods of deafness at intervals, which appear to have been the epileptic equivalent. These attacks have continued for years, and have now brought on dementia, headache, uneasiness, and in-somnia. There can be little doubt on looking back over the history of this case that hæmorrhage had been caused by the injury to the head, which produced

pachymeningitis, and has now left in its train a form of chronic meningitis, with great thickening and induration.

RECURRING SARCOMA.

Schiller showed a lad, æt. 14, on whom he had operated several times for a recurring sarcoma on the upper part of the right tibia. The method he adopted was that of Mikulicz' conservative treatment. The tumour was incised a few centimetres around, and completely removed by opening the knee-joint, into which it had finally extended, involving the whole of the cartilage. The last operation involved the upper third of the tibia, which has caused the entire removal third of the tibia, which has caused the entire removal of that portion of the bone. This defect has been repaired by Hahn's osteoplastic operation, and the head of the fibula so placed that both condyles are brought into contact with it. With plaster and bindings the whole was retained in position till the healing was complete. Again, it was observed that the sarcomatous process had reappeared. Röntgen therapy was next applied, and Holzknecht's homogeneous rays applied, with a happy result. The historical examination revealed large spindle-should contact the sarcomatous processed that the sarcomatous processes the sarcomatous proc logical examination revealed large spindle-shaped sarcoma cells with the giant cells.

# LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE CENTRAL MIDWIVES BOARD AND SEPSIS RE VAGINAL EXAMINATIONS IN MIDWIFERY DURING LABOUR.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,-Now that the new order in the medical profession-Midwives-has been established by law, and come to stay with us, everything ought to be done in the way of preliminary education, and the instruction, before going in for actual "training," should before going in for actual "training," should be sound. Then, the "training" after joining ought to be as thorough as possible in the use of catheter and speculum; the making of tampons or plugs; the names and uses of instruments—the various appliances that the medical man or woman may require, when perhaps there is no help at hand, but the midwife. I go so far as to say the well-trained midwife ought to be able to give chloroform, and to use the hypodermic syringe, and the different medicaments which may be required to be administered through it.

I deplore the three months' course.

What can be learned so as to be retained and utilised in that time? And then if the student be rushed through her 20 cases, and has no time for quiet study and thinking over her case, what will she be able to do when in practice? And if she do not get into practice (supposing she has gained her certificate) all will by degrees be slipping from her, till she feels unfit for her work when called

to fill a post.

The land is flooded with midwives. Can berths be found for all? And will the three months' cramming, or the rush through 20 cases avail her much in times of need? Will she not always have to be sending for

the doctor?

Why the subdivision into midwives and "monthly nurses?" I maintain that every "monthly nurse" should be a well-trained midwife, and not in any way a lower or inferior grade; indeed, she should be on a par with the best trained and accomplished midwife, since she is entrusted with the care of the young mother and of the new infant life.

I am, Sir yours truly,
G. DE G. GRIFFITH.

London.

MEDICAL ATTENDANCE IN HOTELS.

To the Editor of The Medical Press and Circular.

SIR,—With the growth of large hotels a certain number of new abuses have sprung up. One of these, comparatively rare, I hope, in England, is the association with the management of a special doctor, who is, so to say, foisted upon the visitors when they require medical attendance, and whose charges are often much higher than those generally current in the

locality. One of my own patients, a lady of small means, was most unfairly victimised a few days ago at a Swiss mountain resort, which I think better not to specify. Suffering from a slight sore throat, she was compelled to call in the hotel doctor, who prescribed a simple gargle, and called subsequently three times, when all symptoms had disappeared, to see how things were going on. In due course a bill of 200 francs, at the rate of £2 a visit, was sent in and paid, the lady not liking to make a fuss, although she was quite aware of the fact that the doctor who attended was a shareholder in the hotel and in league with the management, and that she could have had the services of the outside practitioner for 10 francs a visit. This, matter, I think, will interest many of your readers, and I trust you will find room for my complaint in your valuable columns.

I am, Sir, yours truly, AN ENGLISH DOCTOR ABROAD.

THE NEWSPAPER PRESS AND QUACKERY. To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—At an inquest in a neighbouring county during last year, the facts discussed in the correspondence now going on in your pages under the above heading

were forcibly exemplified. A child had died without medical attendance until in a moribund condition. The autopsy revealed double pneumonia as the cause of death. The parents, questioned as to the reasons. why they had not called in a doctor, stated that they had placed reliance upon an "infallible cough and lung cure" advertised in the local papers, and had continuously dosed the child with it from first to last. The coroner made some strong remarks about the folly of the parents, but did not suggest any inquiry into the composition of the nostrum, and a verdict of "death from natural causes" was returned. The name of the quack medicine was, of course, given by the parents, and frequently mentioned in the course of the inquiry. It was, however, entirely suppressed of the inquiry. It was, nowever, entirely suppressed in the reports of the case in every one of the local papers. Every one of these papers had contained, and still publishes regularly a puff of the infallible lung "cure." This is printed in the form of an editorial paragraph, and, being varied from week to week, serves, no doubt, to lead simple readers to believe that the medicine is really recommended by the newsnapers. The quack medicine trade is justly stigmatised by one of your correspondents as not only fraudulent, but cruel and deadly; and what can be said of newspaper proprietors whose chief profits are derived from this traffic, with the character of which they must be fully acquainted?

I am. Sir, yours truly,

A SURREY DOCTOR.

Near Reigate, March 12th, 1909.

OXYGEN IN SPORT.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—I am not confusing any point at issue, as Dr. Oscar Jennings says. Dr. Jennings wrote a letter to your journal which must have been based on some paragraph in the daily Press and therein charged me with publishing observations on the effect of oxygen on athletes, unsupported by any exact experiments, and at the same time claimed the priority of having made exact observations on the effect of oxygen on athletes. Dr. Jennings had no justification for making such an attack upon me. If he had sent a copy of his paper to me, it would have received my attention, and I should have acknowledged with pleasure the priority of any work that Dr. Jennings had done. Dr. Jennings' paper had not received notice in any of the standard books of reference which I have consulted, such as the "Handbuch der Sauerstafftherapie," edited by Michaelis, to which the leading German authorities, such as Loewy, Zuntry, and v. Schrötter have consuch as Loewy, Zuntry, and v. Schrötter have con-tributed, and was unknown to English physiologists. If Dr. Jennings had any conception of the enormous output of medical papers in Europe, mostly rubbish, and few of sterling worth, he would recognise the fact which all scientific men know that every new point must be discovered more or less a dozen times over indifferent countries, and that discussions on priority are not worth the paper they are written on, and he would not make an unwarrantable attack on me for not having discovered and published to the world the fact that he had written a paper on "Oxygen in Sport" in a weekly Parisian medical paper. The fact that oxygen helped an athlete to run, and especially when not in perfect training, was found to be the case by W. G. George twenty-five years ago, so there is no priority to be claimed in that.

Now as to the physiological explanation of this fact. Dr. Oscar Jennings claims the priority of having discovered that oxygen inhalation restores the blood pressure when lowered by forced exercise, and bases his claim on sphygmographic tracings. I am most willing to give him the priority he claims, but I re-assert that the sphygmograph is not an instrument by which blood-pressure can be measured; that it is difficult to apply it twice without modifying the form of the tracings obtained, especially by the old method of band-fixation, and that I myself have by this means hitherto been unable to obtain trustworthy evidence as

to the effect of oxygen.

Next Dr. Jennings says: "I demonstrated what he (Leonard Hill) has since ascertained, that oxygen in restoring wind did so by restoring the adequacy of the lung." But this is the very thing which I have not ascertained. The inhalation of oxygen after forced exercise has no effect on the breathing volume or the breathing frequency, as is shown by the figures by Mr. Martin Flack and published in the Journal of Physiology. The carbonic acid produced in the body regulates the breathing frequency and the volume. Oxygen acts on the heart, and restores the blood pressure, and lowers the pulse rate, and increases the neuro-muscular power of the man, it does not act in restoring wind by restoring the adequacy of the lung.

restoring wind by restoring the adequacy of the lung. Lastly, Sir, I stated that "I had ascertained that oxygen and exercise can be used as a valuable method of treatment;" this was in answer to your criticisms, which seemed to imply that the experiments of Mr. Martin Flack and myself were simply directed towards doping in sport. I never claimed to have discovered this, as Dr. lennings says, for I know too well that no discovery is ever made by one man, but that each worker adds but a little brick, sometimes, if he is lucky, a finishing one, to the buildings of Science. When Dr. Jennings claims the priority of this "invention," I am only glad that he should take it, and leave me to work out, as I am now doing, the exact extent to which oxygen inhalation influences the metabolism of the "working" man.

I am, Sir, yours truly,

LEONARD HILL.

Loughton, March 14th, 1909.

# SPECIAL ARTICLES.

LUNACY IN IRELAND. (a)

The Report of the Inspectors of Lunatics for Ireland for the year 1907 shows that the number of lunatics under care is still increasing. There was, in fact, a total increase of 164 during the year, the corresponding increase for the previous year having been 189. In last year's report it was pointed out that, with one exception, viz., 1893, when the increase amounted to 152, the increase during 1906 was less than that which took place during any of the previous 21 years. The increase in 1907, although slightly greater than that which took place in 1893, was 25 less than the increase which occurred in 1906. Further, the increase in 1907 was 295 less than the average increase for the preceding ten years, which was 459. When we study a long period of years, the increase is very striking. In 1880 the total number of lunatics under care in Ireland was 12,982; in 1907 it was 23,718. During the same period the population of the country has been steadily talling, and therefore the ratio of insane to sane inhabitants has apparently more than doubled in less

than thirty years. The actual figures are: in 1880 a proportion of 250 lunatics under care to 100,000 of the population, and in 1907 a proportion of 542. Of course, these figures may give an exaggerated notion of the amount of insanity in the country, for there is no doubt that there are much fewer insane not under care now than in 1880. We regret to note that, of the total number, there are still 3,053 in workhouses.

The inspectors remark that the connection between

insanity and tuberculous disease has been long recognised, and the prevalence of phthisis amongst the insane, whether confined in asylums or not, point to the importance of the subject in dealing with insanity. During the year 1907 the number of deaths in Irish District Asylums ascribed to phthisis was 400, giving a proportion amounting to 26.9 per cent. of the total deaths from all causes. Amongst the general population of Ireland in 1906, 12 per cent. of the total deaths were returned as due to this cause-being less than half the percentage amongst the insane in District Asylums. Attention is drawn to the measures adopted at Mullingar, Clonmel, and some other asylums to provide segregation wards for tuberculous patients, where fresh air treatment can be applied. Very few deaths occurred from general paralysis. Formerly this disease was almost unknown in Ireland, and even yet, with the exception of Belfast and Dublin, it is more rarely met with than in any other country in Europec.g., the proportion of deaths from general paralysis was 3.7 per cent. of the total deaths occurring in District Asylums in Ireland during 1906, whereas in the English asylums during that year it was 16.8 per cent. Attention is drawn to the great need for pathological study bearing on insanity in Ireland. In only 252 cases out of 1,486 deaths, was the cause of death verified by autopsy. Seven deaths by suicide occurred. In several asylums there were more or less serious outbreaks of typhoid fever. Thus, in Cork, there were 49 cases, in Ballinasloe 13, in Mullingar 7, in Ormagh 8, with no less than 4 deaths. The general death-rate varied much in different asylums, the lowest rate being in Waterford (4.2 per cent. of the average number resident), and the highest in Sligo (11.7 per cent).

The inspectors pay a well-deserved tribute to the memory of Dr. Conolly Norman.

# REVIEWS OF BOOKS.

THE EDINBURGH ATLAS OF OBSTETRICS. (a) THE third section of this Atlas has now been issued, and contains a most interesting collection of photographs. The first two of these show respectively the mamma of a multipara" and "the abdomen of a gravid multipara." The next two show certain diameters of the fœtal head. The next two show the positions of the head in a vertex presentation. In them the head is shown at the pelvic outlet, whereas, to show the position, it should be at the pelvic brim. Further, even if the authors desire to show the head at the outlet, flexion should be more marked. The next three photographs show the birth of the head. They are taken from life, and are good. The next photograph is blurred, and might as well have been omitted. next two photographs show the third stage of labour. The next four photographs are anatomical, and show placentæ and puerperal uteri. In one, Fig. 64, the condition of the uterus is pathological, and this should have been stated in the text. The next two photographs show feetal heads—some unmoulded and some de-formed. The next half-dozen photographs show the forceps and its application. They are uniformly good, but it was a mistake to show the assistants and operator with ungloved hands and unprotected arms. and he last photograph of the set shows a patient in Walcher's position.

<sup>(4) &</sup>quot;Lunacy in Ireland." The Fifty-Seventh Report (with Appendices) of the Inspectors of Lunatics (Ireland), for the year ending December 3|st. 1907. Dublin: H.M. Stationery Offices (Cd. 4302).

<sup>(</sup>a) "The Edinburgh Stereoscopic Atlas of Obstetrics." Edited by G. F. Barbour Simpson, M.D., F. R.C.P.E., F.R.C.S.E., F.R.S.E., Senior Assistant to the Professor of Midwifery in the University of Edinburgh, and Edward Burnet, B. A., M.B., B.Ch. With a preface by Rir Halliday Croom, M.D., F.R.C.P.E., F.R.C.S.E., Professor of Midwifery in the University of Edinburgh. In four Sections, each containing 25 subjects, with descriptive text. Section III. London: The Carton Publishing Company. 1908.

We congratulate the authors on these photographs, and the only adverse criticism we have to make on them is that they are too many different subjects mixed up together, only one of which can be regarded as finished-namely, the subject of forceps' application. One section alone now remains to complete the Atlas, and how the authors expect to crowd the remainder of obstetrics into it we do not know. Amongst the obstetric diagnosis, the mechanism of labour, all obstetric operations except the application of the forceps, and all pathological conditions except contracted pelvis. In other words, so far the authors have only touched on the fringe of their subject, and if they want the work to be an Atlas of Obstetrics, they must expand at least fourfold. We trust that the well-deserved success of these initial sections will be such as to justify the publishers in continuing their

## DISEASES OF THE NOSE, THROAT, AND EAR. (a)

In writing this volume Professor Ballenger has taken infinite pains to acquire the opinion of many of the most eminent specialists throughout the world in these three affiliated regions of surgery. Consequently, his book bears the stamp of authority which is enjoyed

by very few text-books on these subjects.

The author has divided his work into three parts. Part I. deals with nasal diseases. In this section Professor Ballenger lays great stress on the importance of correcting all deviations of the nasal septum, which he considers the fons et origo of many of the pathological conditions which affect the nasal chambers and their accessory sinuses. The method most strongly advocated for correcting these deformities is Killian's sub-mucous resection of the septum, whereby the proper ventilation and drainage of the nasal cavities are assured. In Part II., which deals with the pharynx and fauces, the importance of providing for ventilation and drainage is forcibly emphasised by the fact that many of the diseases of these parts are secondary to diseases of the nose. As regards the treatment of hyper-trephied tonsils and adenoids, we are entirely in accord with Professor Ballenger in condemning chloroform anæsthesia in cases of operation for their removal. Moreover, the author's method of extirpating the tonsil with its capsule intact is one which must appeal to all who have had the experience of recurrence which but too frequently follows their partial removal by other means

Part III. deals in a very admirable and thorough manner with diphtheria, tracheotomy, and intubation. A very concise and explicit account is given of the use of the bronchoscope and œsophagoscope in the diagnosis and treatment of diseases and of foreign bodies

in the air passages and gullet.

The chapter on neoplasms of the larynx and their surgical treatment is exhaustively and well illustrated. We have nothing but praise for Part IV., which so clearly treats of the anatomy, physiology, and pathological conditions which are found in the ear. The various tests usually applied in diseased conditions of the organ of hearing are fully described. The chapters on suppurative otitis media and mastoiditis are particularly extensive. The descriptions of the mastoid operations are exceptionally full and thoroughly illustrated by a series of well-executed drawings. complications of middle ear suppuration as brain abscess, thrombosis of the lateral sinus, and facial paralysis, receive appropriate attention.

The book closes with a short chapter on deaf mutism. the ætiological factors of which are briefly discussed.

We can heartily recommend Professor Ballenger's work to both specialist and general practitioner, with the fullest assurance that it will be duly appreciated by all who have the good fortune to read it. From beginning to end the volume is clear, explicit and concise, and throughout the text is beautifully illustrated by some 500 original drawings and photographs.

# LITERARY NOTES.

MESSES. BALE, SONS AND DANIELSSON have sent us a copy of a new chart, which has been designed by the superintendent of a large sanatorium in order that the particulars of each case may be kept uniformly from day to day for three months, and be available at any moment for reference. They can be obtained singly or bound in books of 25.

Mr. Wells is always up-to-date in his literary methods, and his new novel, "Tono-Bungay," describes with remarkable power the methods adopted in advertising a worthless patent medicine, and how an enormous fortune was made out of it. The book is well worth perusing by all who are interested in the suppression of one of the greatest evils of modern times. It should appeal specially to all members of the medical profession, to whose earnest attention we cordially recommend this "novel with a purpose."

MESSRS. WILLIAM HODGE AND Co., Edinburgh and Glasgow, will publish shortly a small book by the Rev. Father Power, S.J., Edinburgh, entitled, "The Alcohol Case: The Summing-up. A Medical, Legal, and Historical Sketch." In this book the author's contention is that in some cases alcohol is deserving, like other poisonous or semi-poisonous drugs administered by skilled hands, of the epithet of "life-preserving," but that of its own nature it must be classified among the death-dealing agents that make more or less successful war on human life. Father Power belongs to the London Society for the Study of Inebriety, and has studied his subject not only in the vast literature bearing on alcohol, but in the vaster host of victims of alcoholic disease.

## NEW BOOKS AND NEW EDITIONS.

THE following have been received for review since the publication of our last monthly list:—

BAILLIERE, TINDALL AND COX (London).

The "Nauheim" Treatment of Diseases of the Heart and Circula-tion. By Leslie Thorne Thorne, M.D., B.S.Durh., M.R.C.S. Eng., L.R.C.P.Lond. Third Edition. Pp. 82. Price 3s. 6d.

net, Third Report of the Wellcome Research Laboratories at the Gordon Memorial College, Khartoum. By Andrew Balfour, M.D., B.Sc., etc., etc., Illustrated. Published for the Department of Education, Sudan Government, Khartoum. Pp. 477.

# **NEW PREPARATIONS.**

MESSRS. PARKE, DAVIS AND CO.'S NEW VACCINES.

This well-known firm has sent for our inspection three new vaccines issued by the Department for Therapeutic Inoculation at St. Mary's Hospital, W., under the direction of Sir A. E. Wright, M.D. Two of these vaccines are provided for the treatment of varying forms of acne. The mixed vaccine for acne contains are million staphylogogic and Smillion. varying forms of acne. The mixed vaccine for acne contains 200 million staphylococci and 8 million acne bacilli per c.c., and is applicable for cases in which the staphylococcus is playing the more important part, as those in which the lesions assume a subfuruncular form. The Acne Bacillus Vaccine contains acne bacilli alone (8 million per c.c.) and is applicable for cases in which the staphylococcus, if present is but a subordinate factor, as in non-pustular present, is but a subordinate factor, as in non-pustular forms with comedones as a principal feature. The needs of suppurative forms of acne are met by the Staphylococcus Vaccine (in dilutions of 100, 200 and 500 million per c.c.), which has been supplied for some time past. The third new vaccine—Neoformans Vaccine—is issued for use as an auxiliary to other treatment of cancer, of which it is found to relieve pain by suppressing local inflammation, whilst it also appears to prolong life by diminishing the cachexia. It is not claimed to be a curative agent. It is prepared from the micrococcus neoformans of Doyen, of which it contains 30 million per c.c.

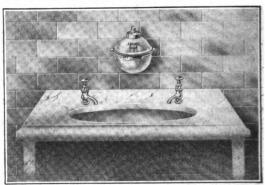

BURROUGHS WELLCOME'S ERGOTOXINE.

WE have been favoured with specimens of ergotoxine by Messrs. Burroughs Wellcome. They controvert the statements that the alkaloid ergotoxine is not yet obtainable in the pure state, and that its action in causing paralysis of the motor fibres in the

sympathetic is due to the presence of some impurity. The deduction has been drawn that it is better to use a fresh and properly standardised liquid extract of ergot rather than ergotoxine, in all cases where it is desired to excite the uterus powerfully or to raise blood pressure. Further, the suggestion has been offered that cornutin should be adopted as a synonym for ergotoxine. The specimen of pure ergotoxine or ergotoxine. The specimen of pure ergotoxine phosphate submitted to us demonstrates that the first statement is misleading. The salt has the formula C35 H41 O6 N5, H3 PO4, H20, crystallises in needles, melting at 186—187° C., and from it the alkaloid ergotoxine can be regenerated in a state of chemical purity. The physiological action of ergotoxine was investigated by H. H. Dale, M.A., B.C. (Biochem. Journ. II., 240-299, 1907), and it was clearly shown that, while ergotinine is practically inactive, the familiar effects of ergot on the blood pressure and the uterus, and in the production of gangrene, are all produced by pure ergotoxine and its salts; in addition, they were found to produce the secondary paralytic effect on motor fibres of the sympathetic system which Dale had observed with many preparations, and which is characteristic of ergotoxine alone among pharma-ceutical principles of which the action has yet been examined. There is as little justification for the sug-gested identity with cornutin, which is the name given by Kobert in 1884 to an impure alkaloidal resin which he obtained from ergot, and which had, as its distinctive physiological characteristic, the property of producing convulsions. The suggestion that ergotoxine and cornutin are synonymous is, in fact, directly opposed to the conclusion of all those who are entitled to express an opinion on the subject.

A LIQUID SOAP DISPENSER.

We have had placed at our disposal a most ingenious contrivance for the dispensing of liquid soap. The object is to substitute a handy method of obtaining the necessary amount of soap for cleansing purposes in liquid instead of solid form. The saponaceous fluid is stored in a glass globe, and when the latter is tilted a few drops of liquid soap are ejected from the nozzle at the top, and washing is conducted in the usual manner. The economy and convenience of this plan are obvious, and a little consideration will show that there are obvious advantages in doing away with the old-fashioned cake of soap. A future may safely be predicted for the soap dispenser in hospital practice. It may stand upright upon the edge of the washing

basin or be fixed over the latter against the wall. When required in aseptic work it can be fitted with a contrivance worked with a foot lever whereby the soap is ejected without touching the apparatus with the hands. From personal experience we are inclined to agree with the claims of the proprietors of this clever little American invention that the plan is cleanly, sanitary, expeditious and economical. The dispenser is sold at the moderate wice of tee for and or call at the moderate wice of tee for and or call at the moderate wice of tee for and or call at the moderate wice of tee for and or call at the moderate wice of tee for and or call at the moderate wice of tee for and or call at the moderate wice of tee for and or call at the moderate with the hands. the moderate price of 10s. 6d., and an excellent liquid soap is supplied at a cost of 10s. 6d. per gallon, unscented, or 12s. 6d. scented. It is, of course, open to anyone to add any antiseptic or other drugs that may be considered advisable. The English agent is Mr. Charles Flint, 25 Victoria Street, Westminster, Charles Flint, London, S.W. 25

# OF RECENT MEDICAL LITERATURE, Summary ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

Tuberculosis of the Cæcum.—(Rogers, Surg., Gyn., and Obst., viii., 2.)—Tuberculosis affecting the cæcum occurs in two distinct and well-defined forms:—(1) Tuberculosis having its focus of infection in the mucous membrane and affecting usually the lower ileum and excum simultaneously. (2) The hypertrophic tuberculosis of the French, confined chiefly to the excum. The first variety occurs almost entirely secondary to an advanced tubercular lesion elsewhere in the body, usually secondary to pulmonary disease, having been excited by the sputum swallowed. Hypertrophic tuberculosis of the cæcum, unlike the ulcerative form, is usually a primary affection; the most probable conclusion is, that the infection is brought about by ingested food. The affection is limited nearly always to the cæcum alone, and extends along the colon. The origin of the disease is ordinarily in the submucous layer of the gut wall affecting the lymphatic structures in this situation; less commonly the process apparently begins in the sub-peritoneal structures. The process is exceedingly slow, and the foci of infection, which may be limited to one portion of the gut wall, or may be distributed more diffusely, act as a kind of irritant exciting an inflammatory reaction which constitutes the so-called sclerous evolution, through which the walls of the cæcum become enormously hypertrophied and thickened, and the cæcum presents the appearance of a real neoplasm. The cæcum externally is irregu-larly nodular in outline, and is intimately associated larly nodular in outline, and is intimately associated with the pericæcal gut, which has undergone a fibrous change, such as the fibro-lipomatous change round a tubercular kidney. The mesenteric glands in the ileocæcal angle are, as a rule, involved, and the appendix is usually affected secondarily, and may possess the same hypertrophic changes that occur in the cæcum. The diagnosis of a tubercular process in the cæcum is extremely difficult, and without a minute examination into every detail of the history of the case and physical findings an incorrect diagnosis will be made physical findings, an incorrect diagnosis will be made in the vast majority of cases previous to an abdominal section. Even when the growth has been removed, it is difficult in a number of cases, without an exploration of the tumour, to say whether one is dealing with tuberculosis or cancer. When dealing with a case owing to the lesion being in the right iliac fossa, there is a strong tendency to conclude that the appendix is at fault, but the general condition of the patient, and the long duration of symptoms with persistence of tumour, should point to either tuberculosis or cancer. In differentiating these, no single symptom, and hardly a group of symptoms, is characteristic of either, and all the evidence is only of limited value. The chief differences are the younger patient, great chronicity, tendency to extend in the length of the gut, and marked tendency to stenosis in tuberculosis, while blood and pus in the stools is strongly in favour of cancer. A tubercular lesion elsewhere is strongly suggestive F.

An Analysis of Eighty Consecutive Cases of Ectopic Gestation.—Frank (Amer. Journ. of Obs., lix. 2). This paper is based on the records of eighty unselected consecutive cases of ectopic gestation. Only one patient was below the age of twenty years. Divided into three periods of five years each, covering the ages from 20-35, each of the five years show an equal number of cases. In the entire series, only twelve patients had never been previously pregnant, and of these six had been married less than one year. Ten women had had no pregnancy for more than four Ten women had had no pregnancy for more than four years preceding their present illness (12.5 per cent.), while six (7.5 per cent.) acquired ectopic gestation in the first six months of marriage. From this it seems that sterility plays but a subsidiary part in ectopic gestation. Of the eighty cases, just half (40) were

overdue in their menstrual history. In the majority of the remainder the menstrual period had not been skipped. Spotting occurred at some time during the course of the illness in a large majority—72.5 per cent. Pain was complained of in almost every case. In 60 per cent. the pain was definitely located to the right or left iliac fossa, in the others the pain was felt over the entire abdomen. In only six cases was the pain on the opposite side to the gestation. It was generally described as knife-like or cramp-like. On admission, forty-six of the patients had a temperature from 98.6-100 degs. per rectum. In the others temperatures above 100 degs. were noted. No striking differences between the variety of ectopic encountered (rupture, abortion, hæmatocele) were shown, with the exception of infected hæmatoceles. A few actively bleeding patients, in collapse, had subnormal temperatures, but not sufficient to aid in diagnosis. The pulse rate is often accelerated by excitement, and con-sequently a source of error, but the quality and regularity are less likely to mislead, if attention is paid to the general appearance of the patient, the degree of pallor, the circulation in the extremities, and degree of pallor, the circulation in the extremities, and the amount of air-hunger, if present. Local signs.—
The uterus, with few exceptions, was somewhat increased in size and softened. In one case where lactation amenorrhoea was present, and in another the subject of chronic adnexal disease, the uterus was very small. In 80 per cent, of the patients a mass was palpable in one of the fornices or in Douglas' pouch. The mass was usually described as boggy and was regularly tender to pressure, and pulsation in the pouch. The mass was usually described as boggy and was regularly tender to pressure, and pulsation in the region was increased. The discovery of a mass in connection with a history suspicious of ectopic in almost every instance was sufficient to assure a correct diagnosis. The physical examination of the 80 cases showed as follows:—No physical signs, 7; mass present, 63; mass absent, 8; mass doubtful, 2. Morning vomiting and increase in the size of hearts was repeatedly noted. Fainting one or more times occurred in 32 per cent. of the cases, and was looked upon as a valuable symptom. Blood counts were not indicative of any particular condicounts were not indicative of any particular condi-tion. The great majority of cases demanding imme-diate operation according to the indications followed in the service, were ruptures of the tube. The only hæmatocele, opened at once after admission, was very large, and caused obstructive symptoms and great pain. large, and caused obstructive symptoms and great pain. The abdominal method was preferred in nearly all cases, five operations for other than well encapsuled hæmatoceles, were started per vaginam, and of these three required immediate abdominal section for hæmorrhage, uncontrollable from below. Even small hæmatoceles bulging downwards into the vagina are probably better treated by laparotomy, which requires a shorter stay in hospital than by the vaginal method. If the patient with hæmatocele shows signs of infection, the vaginal route is followed of necessity. There were three deaths in 80 cases. (1) Hæmatocele aspirated per vaginam, followed by peritonitis. Laparotomy and pan-hysterectomy five days later. Laparotomy and pan-hysterectomy five days later.

(2) The patient was curetted owing to wrong diagnosis. Laparotomy for collapse, which was extreme one hour after curettage, owing to internal bleeding.

(3) Patient admitted in profound collapse, immediate operation, active bleeding found continuing. The first death cannot be ascribed to the ectopic gestation nor the immediate operation. The second was due to wrong diagnosis and the masking of conditions by the anaesthetic. In the third case the nation was in extension and still bleeding. case the patient was in extremis, and still bleeding. Complications met at operation were very few. Only in nine cases were old inflammatory conditions met with, and none showed dense adhesions. Conclusions: No possible examination should be carried out and

cureftage not done till ectopic is absolutely excluded. If after two or three days the condition had not definitely improved, and no marked tendency to hæmatocele developed, laparotomy is indicated. Should severe attacks of pain, fainting, or collapse ensue during period of waiting, operate at once. In well-defined hæmatoceles vaginal section and drainage suffices, but convalescence is more prolonged than by laparotomy. If a patient when first seen is in a pre-carious condition, it is safer to err on the side of early operation than to wait.

The Best Methods of Promptly Terminating the First Stage of Labour, with Special Reference to Vaginal Cesarean Section.—Fry (Amer. Journ. of Obst., lix., 2.)—When prompt or rapid evacuation of the uterus is indicated, in the interests of mother or child, one can now choose between manual dilatation, and the indicate of the case multiple incision of the cervix, instrumental dilatation and vaginal Casarean section. The anatomic and physiologic conditions of the cervix furnish the key to the situation, and should be the guide for determining the method applicable to each particular case. As a rule, manual dilatation and multiple incisions are applicable only after obliteration of the canal, while instrumental dilatation and vaginal section are required when the cervix is intact. Multiple incisions are intended to overcome the resistance of the external os, therefore effacement of the cervical canal is a pre-requisite to its employment. Vaginal section is a surgical procedure that overcomes the complication by correct surgical principles. A powerful sphincter muscle that is unprepared by Nature for dilatation is cut, and the obstruction overcome with little danger of subsequent laceration. Instead of leaving lacerated author reported fifteen cases of eclampsia, with one maternal death, of which twelve were treated by vaginal Cæsarean section and delivery In his paper he reviews the teaching of recent books, and con-siders that the merits of vaginal section are not recognised when the indications exist for prompt evacuation of the uterus with an intact cervix, while the operation has been sufficiently tested to warrant confidence

Pathology and Treatment of Purulent Pleuritis. Billings (the Journ. Amer. Med. Assoc., January 23rd, 1909) discusses the pathology and treatment of puru-lent pleuritis. He dwells especially on two forms of treatment, that of continuous suction as advised by Dr Joseph Bryant, and the injection of formalin in glycerine, as recommended by Dr. John Murphy. In the case of infection by the pneumococcus, where the prognosis is comparatively favourable, the treatment by Bryant's method has certain advantages over the older treatment of resection of a rib and drainage. Not only is the exudate evacuated in this way, but the influence of the negative pressure, supplemented by the normal respiratory movement, is of great benefit in expanding the former atelectatic lung. By this method the average duration of the treatment is said to be the average duration of the treatment is said to be considerably shortened. In Murphy's method the pus is first evacuated by aspiration, and then from one to five ounces of a 2 per cent. solution of formalin in glycerine is injected into the pleural cavity. The treatment is repeated in ten days or a fortnight, if necessary. Dr. Billings reports seven cases treated in this way. Of these three died, but two were practically hopeless when treated. Of the four that recally hopeless when treated. Of the four that recovered, all, except a woman, æt. 30, were children. The average number of injections were two, and the length of time from the first injection to the discharge of the patient was from four to six weeks. All the cases were metapneumonic.

# **OBITUARY.**

DR. JOHN HENRY KEELING, OF SHEFFIELD. We regret to anounce the death of Dr. J. H. Keeling, which took place at his residence in Sheffield on the 13th inst., at the age of 77. He was born at Malta in 1831, and proceeded in due course to Edinburgh Uni-

versity, a medical career having been decided upon, and after studying there from 1848 to 1852 he received his degree of M.D.

On leaving Edinburgh he continued his studies in London, and spent some time also in Paris and Vienna, where he attended the practice of the most distinguished men in those Capitals. In 1869 he became a Fellow of the Royal College of Surgeons. In a reflow of the Royal College of Surgeons. In 1854 the war against Russia broke out, and Keeling went to the Crimea as surgeon in the Turkish Army, a service afterwards rewarded by his appointment as officer of the Order of the Medjidieh. As early as 1860—March 27th—he was appointed Lecturer on Medical Jurisprudence at the Sheffield Medical School, thus beginning an association with the teaching as well as the practice of medicine in Sheffield, which lasted for nearly 40 years. Four years later Dr. Keeling as the practice of medicine in Shemeld, which lasted for nearly 40 years. Four years later Dr. Keeling became Lecturer on Physiology. He resigned the Lectureship in Physiology, and was appointed, in conjunction with Dr. Aveling, to lecture on his special subject, "Midwifery and Diseases of Women." He continued to lecture on that subject for 32 years.

After his retirement from an active connection with

the Royal Hospital, he, at the request of his colleagues, the Royal Hospital, he, at the request of his colleagues, remained a member of the Clinical Committee, which regulates the teaching at both the Royal Infirmary and the Royal Hospital. The Jessop Hospital, the Public Hospital and Dispensary, now the Sheffield Royal Hospital, also enjoyed the benefit of Dr. Keeling's services. He was elected Surgeon of the Hospital in 1867, in place of Mr. J. F. Wright, resigned, and held the post for 25 years.

the post for 25 years.

# MEDICAL NEWS IN BRIEF.

Contract Practice at Manchester.

MR. GEORGE WILDE, President of the National Friendly Societies' Conference, which represents a membership of nearly five millions, made some interesting remarks on the controversy between the medical profession and the Friendly Societies, when seen in Manchester by a representative of the Manchester Evening Chronicle.

"This has been a burning subject for many years," he remarked. "It is quite true that some medical gentlemen are working at contract rates at a small sum. That is due to the doctors themselves. When societies or clubs have advertised for a medical officer by tender, or clubs have advertised for a medical officer by fender, they have generally, like other bodies, accepted the lowest tender. Hence the disparity in prices between one district and another. It is only fair, however, to say that in towns the members of a club or society generally live within a small radius, and in such cases the medical man is able to visit them much more speedily than in country places.

"It would be a good thing, both for friendly socie

ties and the medical profession, if joint meetings could be brought about in various parts of the country to deal with local circumstances and to arrange a rate below which clubs and societies should not ask a doctor to work; but the time has gone by for any move on the part of the medical men to lay down the principle of asking clubs or societies to exclude any of their members who may be earning more than a certain income, or who may be paying above a certain rental, from

medical assistance.

"Many people who have joined friendly societies may be successful in business in later years, but they remain consistent and active workers of the society which gave them their first impetus in social life. In many cases, although they pay their medical benefit contributions, they do not call upon the club doctor. I quite admit that there are exceptional cases, where man who can afford to pay a private practitioner will

claim his full benefit.

"Doctors in many parts have absolutely refused to accept contract rates for women. This has been a great blow to the establishment of women's lodges, and it has convinced the leaders of the friend'y societies that the aim of the medical profession is to do away with contract rates of payment altogether. The knowledge of this fact is causing many friendly and trade socie-

ties to join in the establishment of medical aid associations, and the medical profession will be wise in making up its mind to work in conjunction with these bodies, rather than set its back with a determination to dictate its own terms, either by way of contract, or its abolition."

## Royal College of Surgeons of England.

At the meeting of the Council of the College, held on Thursday last, Mr. Henry Morris, F.R.C.S., Presi-

dent, in the chair.

Mr. Frederick J. F. Barrington, M.B., B.S.Lond., M.R.C.S., House Surgeon to University College Hospital, was admitted a Fellow of the College, and Dr. Claude Edward Freer Fortin, of McGill University, Montreal, and Middlesex Hospital, was admitted a member. Diplomas of the College Licence to practice Dental Surgery were issued to Mr. Reginald Henry Christmas Baker, of the Middlesex and National Dental Hospitals, and to Mr. Henry Vincent Gibbons, of Guy's Hospital Dental School.

A report from the Committee appointed to prepare a new by-law relating to the admission of women to examination for the diplomas of the College was received. The report was considered and the proposed new by-law will come before the Council at their next meeting for further consideration and final approval.

The attention of the Council was called to the petition of the British Medical Association for the grant of a Charter of Incorporation. A committee was appointed to consider the terms of the proposed charter and its bearing upon the position of the College and the rights of its Fellows and members.

Mr. Henry Morris was re-elected the representative of the College in the General Medical Council for the next five years, and Mr. F. Richardson Cross was appointed the next Bradshaw Lecturer for the ensuing Collegiate year.

## Typhus Epidemic in Madrid.

THE authorities at Madrid are seriously alarmed by the typhus epidemic, and are attempting to exercise a censorship over all newspaper telegrams, which necessitates forwarding despatches by an indirect method.

The Mayor of Madrid is the latest victim of the disease, and his condition is serious. Several other pron.ir.ent municipal officials are suffering, and the hospitals are crowded, there being nearly 300 cases in the San Juan de Dios hospital alone.

Between 40 and 50 deaths from typhus occurred during February.

# King's Co lege Hospital.

THE Committee for the removal of King's College Hospital to South London have received a cheque for £2,500 from the trustees of the late Mr. Zunz, this being a second instalment of a grant of £10,000 promised to the fund on the condition that a ward in the new hospital containing not fewer than 20 beds is to be called the "Annie Zunz Ward" in perpetuity.

## A Novel Method for Building Hospitals.

THE Copenhagen correspondent of the Standard newspaper writes that for the last five years the postal December to bear an extra stamp, value about one farthing. The income of this so-called Christmas stamp was intended by the originator of the idea—a clerk at the General Post Office-to found a hospital for consumptive children. Last year saw the amount brought to the sum required for the building, and the foundation-stone is to be laid this week. It is expected that the future sale of this stamp will be sufficient as the population and business increases not only to defray the current expenses attending the up-keep of the hospital, but also to enable the committee to build more hospitals, which are sadly wanted in Sweden.

## " Spiritual Healing."

AT a meeting of the Church and Medical Union, held last week at the Church House, a paper was read by Dr. L. W. Bathurst, in which he discussed the effect which the movement is likely to have on the rela-

tionship between the Church and the medical faculty. He took the line that the profession is very far from being convinced that there is need for any such movement, and, in the second place, held strongly to the view that it cannot be expected to take any share in their attention to administering comfort and consola-tion, and encouraging cheerfulness, prayer, faith, hope, fortitude, and resignation, in accordance with circumstances, so long, says Dr. Bathurst, will the medical profession welcome their co-operation. as regards those who are credited with special gifts in the matter of healing, he declared that if medical men were to submit their patients to them, they would be running altogether counter to the General Medical Council in its efforts to put down unqualified practice. Dr. Bathurst sums up what he conceives to be the opinions of the medical profession on this subject under the following headings:

(1) If the Church wishes the co-operation of the medical profession, she must propound her views and intentions, and say exactly in what manner her proposals are to be carried out.

(2) The medical profession does not recognise the pecial gifts of healing claimed by unqualified and irresponsible persons—claims which, if admitted or sanctioned, could only serve to open wider the door to quackery.

(3) The medical profession cannot, from a practical point of view, be regarded, as has been suggested, as

the handmaiden of the Church.

## Vital Statistics.

THE deaths registered last week in the eighty great towns of the United Kingdom corresponded to an annual rate of 21.3 per 1,000 of their aggregate population. In the preceding three weeks the rates had been 17.5, 18.1, and 19.1.

Measured by last week's mortality, the highest

annual death-rates per 1,000 living were:—From all causes, 28.0 in Rhondda, 28.7 in Stockport, 29.1 in Rochdale, 29.5 in Hanley, 29.9 in Wigan and in Bury, 35.6 in St. Helens, and 26.6 in Dublin. The deathrate from measles was 3.5 in Sheffield, 3.9 in Birmingham, 4.4 in Smethwick, 5.9 in West Hartlepool, 7.2 in Warrington, 7.3 in Aston Manor, and 8.8 in St. Helens; from scarlet fever, 1.6 in St. Helens; from diphtheria, 1.0 in Stockport and 1.3 in Kings Norton; from whooping cough, 1.1 in Suggestion Norton; from whooping-cough, 1.1 in Swansea, 1,2 in Aston Manor, 1.3 in South Shields, 1.7 in Wigan, and 2.7 in St. Helens; and from diarrhoea, 2.0 in Great Yarmouth. No death from small-pox was registered in any part of the United Kingdom.

Navy Medical Service.

In the course of his memorandum on the state of

tue Navy, Mr. R. McKenna says:

The recruiting of the Naval Medical Service has for some time been a matter of anxiety to successive Boards of Admiralty. I have now appointed a Committee to inquire into the Naval Medical Service, composed as follows:

'Admiral Sir John Durnford, K.C.B., D.S.O. (Chairman).

Inspector-General James Porter, C.B., M.D., M.A.

(Medical Director-General).

"Surgeon-General Sir Affred Keogh, K.C.B., M.D.
"Mr. J. H. Brooks, Principal Clerk.
"Sir William W. Cheyne, Bart., C.B.
"Deputy-Inspector-General William H. Nodman,

"Mr. G. L. Cheatle, C.B., F.R.C.S.

"Mr. J. S. Barnes, Admiralty, Secretary.
"We hope, with the able assistance of these gentlemen, that we shall devise some means of putting the Naval Medical Service upon a more satisfactory footing."

## Trinity College, Dublin.

During Hilary Term, 1909, the following candidates Possed the Final Examination in Medicine, Part II.:— Douglas M. Moffat and Albert J. Stals (passed on high marks), John D. Kernan, Henry R. Kenny, Frederick R. Sayers, Charles G. S. Baronsfeather, Denis J. Stokes, Charles B. Jones.

# **NOTICES TO** CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly, requested to make use of a Distinctive Signature or Initial, and to avoid the practice of signing themselves "Beader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January lat and July 1st respectively. Terms per annum, 21s.; post free at home cr abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ORIGINAL ARTICLES on Extrems intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessary for publication but as evidence of identity.

S. C. T.—The power to close schools in epidemic disease does not rest with the school Medical Officer, but with the Medical Officer of Health. When the former officer is subordinate to the latter, there is, of course, no difficulty, but when the offices are distinct and independent of each other, the school officer must work through his colleague. The wisdom of closing schools is frequently questioned, on the ground that the children who would have met in the school then met in the alleys and streets, and infect each other just the same. Our own view is that in epidemic times the precaution is one that should be taken, and in the case of messles in infant departments, it is almost the only measure that can be used.

J. J. S. (Bromsgraye).—It does not follow that because a patient died while under the influence of an anæsthetic that death resulted from the administration. Each case must obviously be judged upon its merits. A further fallacy connected with this subject is the "delayed" deaths which follow within a few days in the case of chloroform, and it may be one or two weeks or more from lung complications in t

with angesthetics.

CLINICIAN (Southgate).—At times severe nervous complications follow measles. In the acute stages those are usually of a texic nature. In rare instances mania and melancholia have been known to follow the malady, but in these cases there is nearly always a history of neurosis.

DR. WARRINGTON.—Your paper is marked for insertion in our next week's issue.

MR. J. E. R.—We are making the necessary inquiries, the results of which will be dealt with in an early number.

# Meetings of the Societies, Tectures, &c. WEDNESDAY, MARCH 17TH.

WEDNESDAY, MARCH 17TH.

## Bacancies.

Middlesex County Asylum, Napsbury, near St. Albans.—Fourth Assistant Medical Officer. Salary, £160 per annum, with furnished apartments board, washing, and attendance. Applications to the Medical Superintendent.

North Riding Asylum, Clifton, York.—Junior Medical Assistant. Officer. Salary, £150 per annum, with furnished apartments, board, washing, and attendance. Applications to the Medical Superintendent.

Surrey County Lunatic Asylum, Brookwood, near Woking.—Third Assistant Medical Officer. Salary, £150 per annum, with board, lodging and laundry. Applications to the Medical Officer. Salary, £150 per annum, with board, lodging and laundry. Applications to the Medical Officer. Salary, £150 per annum, with board, lodging, and washing. Applications to the Clerk to the Board, Embankment, London, E.C.

Royal Victoria Infirmary, Queen Victoria Road, Newcastle-upon-Tyne.—Pathologist and Lecturer on Pathology to the University of Durham College of Medicine. Salary, £400 a year. Applications to the House Governor, Royal Victoria Infirmary, Newcastle-upon-Tyne.

St. Bartholomew's Hospital. E.C.—Assistant Pathologist. Salary.

Newcastle-upon-Tyne.

St. Bartholomew's Hospital, E.C.—Assistant Pathologist. Salary, E300 per annum. Applications to Thomas Hayes, Clerk.

Fermangh County Hospital.—House Surgeon. Salary, £72 per annum. Applications to Secretary, C. Wilson. (See advt.).

MORTON.—On March 10th, at The Lodge, Southbourne Road, Bournemouth, the wife of James R. Morton, M.B.Lond., M.R.C.S., L.R.C.P., of a daughter.

Van Praagh.—On March 13th, at 3, Honeybourne Road, West Hampstend, the wife of Dr. Harold Van Praagh, M.D.Lond., a son (Gordon).

# Marriages.

HOWLETT—LANKESTER.—On March 10th, at St. Nicholas Church, East Dereham, John Kitton Howlett, B.A.Camb., L.R.C.P., L.R.C.S.Edin., L.F.P.S.Glasgow, third son of John Godfrey Howlett of Bracondiale, Nowich, to Nellie Elvira Lankester, eldest daughter of Egbert Rougier Early, of The Firs, Southampton.

TOMEINS—STANION.—On March 10th, at the Parish Church, Morden, Surrey, Charles P. Tomkins, L.R.C.P.I., of Epsom, to Maud Cornelia, daughter of the late John H. Stanton, of Stubb House, Winston, Darlington.

## Beaths.

EDWARDS.—On March 11th, at Higheroft, Chippenfield, King's Langley, Edward Noble Edwards, M.R.C.S.Rng., L.S.A., and V.D., late Colonel commanding 1st Sussex A.V., Brighton. GRIPHTINS.—On March 8th, at Whitehall, Knighton, Badnorshire, William Hughes Griffiths, M.R.C.S. and L.S.A., late of Hinckley, Leicestershire, in his 70th year.

HARDT.—On March 8th, at Aden, of sleeping sickness, on the voyage home from Nyassaland, Captain Frederick Hallam Hardy, R.A.M.C., aged 35, son of Major-General F. Hardy, C.B., York and Lancaster Regiment, Shawford, Winchester Sumprer.—On March 5th, at Dorking, Eustace Wyatt Sumpter, M.B., B.S., and L.D.S., third son of the late Walter Sumpter, M.D., and of Mrs. Sumpter, Cley-next-the-Sea, Norfolk, aged 33.

DICKINSON.—On March 14th, at West Hill, Putney, Charlotte Annie, wife of William Gilbert Dickinson, M.D. WALKER.—On March 14th, at 205, Peckham Bye, of double pneumonia, Charlotte Henrietta, aged 78, wife of J. Wm. Walker, M.D.

# The

# Allenburys Foods

# Special Advantages:

- 1—The close conformity in composition of the Milk Foods to human milk; both fat and proteids being in similar relative proportions.
- 2—The readiness with which the Foods are assimilated; being as easy of digestion as maternal milk.
- 3—Their adaptability as an adjuvant to breast feeding during the period of weaning; no digestive troubles being likely to occur.
- 4—Their freedom from all harmful bacteria; being made from fresh milk, modified, evaporated at a low temperature, in vacuo, and preserved in hermetically sealed tins.
- 5—The ease and exactness with which the Foods can be prepared; the addition of hot water only being necessary.
- 6—Fresh elements of diet can be easily added to the Foods, and are specifically mentioned on each tin.

A reliable substitute is thus provided for the Mother's Milk, when this is wanting or deficient.

## Notes and COMMENTS.

Women and the R.C.S.

THE new by-law permitting the Royal College of Surgeons of England to admit women to its examinations has been published, and will come before the Council at

its meeting next month, when, presumably, it will be passed with little or no alteration. For the wording of the proposed by-law merely carries into effect the already-expressed view of the Council, and there is nothing particularly new and startling in it. The first section lays down that women may be admitted members and Fellows of the College and licentiates in dental surgery, and that in the other by-laws and regulations all words imputing the masculine gender shall also impute the feminine. The second section defines the condition that women shall not be eligible for seats on the Council, nor take part in elections to the Council, nor attend any meeting of Fellows or of Fellows and members, unless purely scientific meetings. Finally, the third section forbids women to be elected examiners. It remains to be seen what value women will attach to these privileges: we should imagine very little, except that of admission to the fellowship examinations. If, however, they enter in any numbers for the membership, we see a vista of struggles for the abrogation of the offensive restrictions placed on their sex, and we cannot help thinking that if the College was going to do the thing at all, it might as well have done it properly.

A Woman's College.

THE strong feeling which exists among the present members that they should be represented on the Council-a feeling with which, as a matter of common justice, we are

entirely in sympathy-may to a certain extent be dissipated by some of the members joining the cause of the women, and seeking to have the sex disqualification removed, and probably the idea that this result might come about acted as an argument with some members of the Council in admitting women. The justice of admitting members to the Council is so obvious that it is impossible to find any argument to repel it, and opponents are bound to rely on tradition and prejudice. Even tradition itself is against them, for members once composed the whole corporation, the Fellows being a mushroom growth of the last half century. But if members are gallant enough to espouse the feminine cause, they will lose sight of their own wrongs, and the College can certainly be relied on for many years to exclude women from governmental places. For our part we cannot see why women should wish to come into the College on the terms proposed. They are a large body and their numbers increase. Why do they no tstart a college

of their own and obtain power to grant their own degrees? Such would certainly be the more dignified course, and examination fees-at College of Surgeons rates—should be sufficient to meet all current expenses.

THE isolation hospital is a sort of Claim Against Ishmaelite amongst that most necesan Isolation sary class of administrative organisations to which it came as a late

recruit. An institution of this kind is looked upon as fair game by every litigious citizen who can formulate a grievance in connection with its sphere of activities. The complainant in an action tried last week at Winchester Assizes may, or may not, have had reasonable grounds for the belief that his little girl contracted diphtheria from an adjoining infectious diseases hospital, but Mr. Justice Ridley dismissed his claim as visionary. The facts were that the plaintiff lived in a house and grounds near Alton with his family and five children. In the summer of 1908 there had been a serious outbreak of diphtheria, and an isolation hospital had been erected adjoining the plaintiff's land. On September 25th one of the plaintiff's children, aged seven, caught diphtheria. On September 21st she had played in her father's field, and crawled under a wire fence, and had approached the hospital where the infected children and the nurses were. She had played with a kitten which originally had lived in the infected hospital.

THE medical evidence in favour of A Thousand-and- the claim was not of the strongest. one Channels It was alleged, for instance, that of Infection, the diphtheria bacilli may have

been discharged by coughing upon the grass of plaintiff's land where the little girl played. The defence urged that there was no proof that the little girl caught the disease by reason of the defendants' fault, and it was necessary to prove that fact affirmatively. Further, the hospital had ceased to exist before the issue of the writ, for the buildings were only used up to October 1st, and it was contended that the defendants had fulfilled all the requirements of the Local Government Board. Apparently the strongest point for the plaintiff was that the absence of a high wall was evidence of some negligence for the jury to consider. Mr. Justice Ridley held that there was no evidence of negligence to go to the jury, for the child might have got the infection in a thousand different ways. He would therefore enter judgment for the defendants with costs, and would certify for a special jury. We are glad to add that the judge refused stay of execution. It is to be hoped that the result of this case may serve as a warning to would-be litigants of a similar order.

An exceedingly interesting paper
Periodicity in was lately read before the Royal
Human Society by Dr. Walter Heape on
Reproduction. some points contained in the vital The numbers statistics of Cuba. dealt with are large, namely 177,704, so that the conclusions are likely to be well-founded. It seems that the ratio of males to females born of white parents is definitely higher than that of those born to coloured people. Of all births, 108.44 males to 100 females is the ratio for whites, and 101.12 males to 100 females for coloured. Again, the ratio is markedly disturbed in the case of legitimate and illegitimate births. In whites, legitimate births show 100 male to 100 female births, illegitimate 105.95 to 100 females; for coloured, there are 107.73 legitimate male births to 100 female, whilst in the case of illegitimate births the proportion is reversed, for there are only 97.91 males to 100 females. Still more curious is the fact that for both races there are two sharply-defined breeding seasons each year, and these seasons are accompanied with marked climatic conditions; such periodic breeding has been hitherto regarded as one of the perquisites of the lower animal kingdom. Also it is shown that at these times of greatest fertility the largest proportion of females are born. We hope that Dr. Heape will continue his studies on these interesting phenomena.

Lead as an Abortifacient.

From the report of an inquest held last week at Sheffield it seems that the abominable practice of selling pills containing lead for the purpose of procuring abortion is still carried

on. A labourer's wife, aged thirty-three, was admitted to the Sheffield Royal Hospital suffering from lead-poisoning, from which she succumbed. The unhappy woman was the mother of nine children, six of whom were living, and it seems that from some source she had obtained diachylon pills to rid herself of a tenth child which she was The husband said he knew nothing about the pills, and no evidence was forthcoming to show how they were obtained, though the woman had told the house-physician that she took four pills a day for a fortnight. It is shocking to think that this criminal and highly dangerous trade can be carried on, and considering all the attendant circumstances, it seems to us that the Government would be acting in the public interest if they made it an offence to sell or dispense lead, except by medical prescription, not to be repeated unless countersigned. Most so-called abortifacients are useless, and their criminal administration does little harm, but with lead the case is different, and the risk, not only of abortion, but of death of the mother, is tremendous.

# LEADING ARTICLES.

THE MEDICAL INSPECTION OF SCHOOL CHILDREN.

The general principle involved in the medical inspection of school children has been treated with acclamation by the medical profession; clearly it is only by enforcing a system of inspection that remediable defects can be brought under control and, as far as possible, remedied. Compulsory registration of this knid, however, is surrounded by many difficulties, involving as it does the expenditure of large sums of public money and a certain amount of interference with parental rights, to say

nothing of the national desire, both of local authorities, and of the central Board of Education, to avoid as far as possible any odium arising out of the matter. The whole administrative problem is still in its tentative stages, and time and experience will be needed to evolve a sound system out of the present defective and, in some instances it may be feared, even uninformed and conflicting essays. In another part of the present issue of the MEDICAL PRESS AND CIRCULAR appears an important communication on the subject from Dr. George Carpenter, who therein recounts his experiences as a medical examiner appointed to inspect some hundreds of school children in a London suburb. The Board of Education, in a Circular dated January 23rd, 1908, refrained from issuing a complete set of forms of examination, thinking it expedient to leave considerable latitude in regard to the particular forms or schedules. The Board, however, issued a schedule indicating particulars, attention to which they regarded as constituting the minimum of efficient school inspection. In adopting this attitude the Board clearly threw the onus of responsibility for any odium that might arise upon the shoulders of the local authority. Dr. Carpenter appears to think that such was the deliberate intention of the Board. Their official schedule was of a far-reaching nature, and in order to meet its requirements, he drew up a practical form for his own guidance. The children were undressed, wrapped in a blanket, and a thorough examination made in the best room that could be obtained for the purpose. The local education authority appeared to think that to undress children for the purpose of medical examination was superfluous, and that the heart could be auscultated by exposing a small area of skin in the neighbourhood of the left nipple. It must be clear to every medical man that it would be impossible to undertake any satisfactory physical examination of a child without removing the clothes. The presence of pediculi, of hernial protrusion, of bone affections, and of many skin diseases, to take a few instances, could not be ascertained in any other way. Yet the Board of Education have apparently left this crucial matter to be fought out between the local authorities and the inspecting medical officer. As Dr. Carpenter very pertinently remarks, if the medical examiner did his duty properly and the parents objected he need expect support and encouragement neither from the local authority nor the Board of Education. If, on the other hand, he did not perform his duties properly, his functions were parasitic rather than medical, and he became an unnecessary burden upon the rates and the taxpayer. These views appear to be cogent and sensible, and we fail to see how they can be disregarded by the Board of Education. A central authority of that importance should be prepared to accept the full responsibility of the details of the measures they are called upon to administer. No matter how earnest and competent the men appointed as medical examiners, they cannot be expected to maintain a high standard unless they have the support of the Board of Education. Nav. more, we hold a strong opinion that the Board is morally responsible for the forming of a fully detailed schedule, general and particular, for the

guidance of school examiners. In no other way can we imagine a permanent solution of the administrative difficulties that beset the way of securing an efficient national service. At the same time we would implore the Board of Education to take some steps to secure medical men of special experience as medical examiners. In spite of the utmost respect for the excellence of the public health service of the United Kingdom, we doubt if the average medical officer of health is qualified by previous experience for the inspection of school children. Such a post requires a long and special experience in dealing with disease, and in cases where feasible should be entrusted to men who have acquired their knowledge in responsible hospital practice. In conclusion, the Minister of the Board of Education may be congratulated on the excellence of the work that has been so far accomplished in the administration of one of the most important social advances of modern times. It is only by free discussion and enlightened criticism that the best results will be obtainable. With that end in view we have thought it well to call attention to the subject in the columns of a medical journal After all said and done, the principle of medical inspection of school children found its genesis in the work of the medical profession, and its success or otherwise in practice will depend to no small extent on the conditions attached to its services by the President of the Board of Education.

## A NATIONAL HOMŒOPATHIC FUND.

Last week at the Mansion House was held a meeting, under the presidency of the Lord Mayor, to forward a scheme for providing a national homœopathic fund. The gathering brought together an odd mixture of big-wigs, aristocratic, legislative, and religious, who surely can never have before met on a platform, together with representatives of twenty-two provincial towns. Lord Cawdor, who seems to combine a faculty for ruling the King's Nav-ee with a taste for the infinitesimal dose, defined the objects of the desired fund in a resolution which, it is needless to say, was passed nem. con. This fund is to assist in the support of homœopathic institutions in the United Kingdom, and in the foundation, maintenance, and endowment of new homoeopathic hospitals, cottage hospitals, and dispensaries in the United Kingtom, and institutions which include amongst their objects support for research into the problems of medicine on homeopathic lines, provision for homoeopathic medical education, the foundation of homoeopathic hospitals for infectious diseases, the establishment of special convalescent homes in situations where they will be available for the homoeopathic patients in large areas, and the establishment of open-air sanatoria, where the medical treatment will be homœopathic. This all sounds very fine and praiseworthy, but we fear the £7,590 18s. 4d. raised at the meeting will not go very far in carrying out such an ambitious programme. Perhaps, however, it is just as well, for now that the homoeopaths have stolen so much of our thunder (even to open-air sanatoria!) there could be nothing but confusion in the public mind if the fund were to start schemes of the sort. As Lord Cawdor said, homoeopathy is not a matter for argument or discussion; it is a matter they

(homœopaths) knew in their daily lives. That is indeed so; it is only by a kind of divine fervour in the breast that homeopathy can find acceptance; it will not stand a moment's scientific argument or discussion. The Lord Mayor, in his opening speech, said that they had not met in any spirit of hostility to orthodox medical practice; on the contrary, they had met to help that practice. Many medical men were sceptical as to the use of drugs, and therefore the time was ripe for calling the attention of the public to the system and practice of homoeopathy. We cannot say that we see anything very friendly in so doing. If medical men are sceptical as to the use of drugs, we cannot see how it will help the "orthodox' practice of medicine to ask the public to be equally sceptical about it, and rush into the extended arms of the homoeopaths. Indeed, the argument seems to be conceived in about as friendly a spirit as if he had said that, because some people think we have not enough Dreadnoughts in England, that we throw in our lot with Germany, when we should find as many as we wanted. However, his lordship, proceeding with the same want of hostility, went on to say that orthodox medicine is a system of empiricism, whereas homœopathy is a system of precision, and that modern research in medicine is tending to prove the accuracy of the homoeopathic law, "for the best results obtained by those of the old school at the present time were obtained from the use of drugs prepared in a way which was distinctly in accordance with that law." No doubt the Lord Mayor was duly informed by his "experts" that these statements are in accordance with facts, but if we pass over the hardlyveiled insult that scientific medicine is a system of empiricism, we can at least inform him that the rest is a farrago of nonsense, and nonsense of a not very harmless type. After this, the Lord Mayor pleaded for an investigation into homoeopathy, saying that the proper thing is to abolish homocopathy altogether, if it were found to contain no truth. It is rather late in the day to ask for an investigation into homoeopathy, for every competent scientific man who has investigated the subject has long since come to the conclusion that the best thing to do with such a tissue of fine-spun crudities is to abolish it altogether. Moreover, to appeal, as the Lord Mayor did, for the brotherly reception of homoeopaths by scientific practitioners is to reverse the order of things. Homoeopaths cut themselves off from the scientific practice of medicine to devote themselves to their cult, and like to be known as homœopathic practitioners, and draw distinctions between themselves and those whom they have themselves christened "allopaths." The practice of medicine is broad and catholic, and there is no reason for homoeopaths to cut themselves off unless they wish. It is both childish and illogical to dissociate themselves from the scientific practice of medicine, and then to whimper because they are not regarded as scientific practitioners. As long as there are cranks in the world there will, we suppose, be homeopaths, osteopaths, and crowds of "paths" of all kinds, but it is comforting to think that in this country these bizarre oddities gain little hold on the general public. Homœopathy is not quite at its last kick, but it is nearing the penultimate.

# CURRENT TOPICS.

# The General Anæsthetics Bill.

For some weeks past there has been considerable debate on the subject of the General Anæsthetics Bill. Few people have any doubt as to the propriety of the principle involved, and few, outside the General Medical Council, object to the obligason to have instruction in anæsthetics made part of the necessary medical curriculum. It is certainly a slur on the efficiency of the Council in supervising medical education, that so important a subject should have to be forced on it from outside. The main point under discussion at present, however, is the question whether dentists should be exempted from the provisions of the Bill. We publish in another column an expression of opinion coming from the staff of the Dental Hospital of Ireland, dentists in the same category with medical which voices the case in favour of placing men. It is pointed out that dental students receive instruction in general medicine and surgery as well as in the administration of anæsthetics, and therefore "the same privileges could with perfect propriety be extended to dentists as are given to medical men" by the Bill. Without in any way questioning the ability and skill shown by many dentists in the administration of anæsthetics, there is much to be said for the view that the discharge of that function is a part of general medical work rather than of dentistry.

# Insanity in Criminal Trials.

WE have often commented on the unsatisfactory condition of the law as to the plea of insanity in criminal trials. The process of establishing the irresponsibility of a prisoner is both cumbrous and unconvincing. It is not often, however, that we have to note an added difficulty, brought about by obstruction on the part of the Government authorities. In the case of a prisoner tried for murder recently at Armagh Assizes-if the statements made in a letter to the press from his solicitor be correcta grave miscarriage of justice was very narrowly avoided. It appears that the solicitor, having reason to believe that the prisoner was insane, applied to the Crown authorities some weeks before the trial to have an examination made by an expert in mental disease. After considerable delay he was informed that there was no reason for such a course. Eventually, on application to the Assize Judge, at the eleventh hour, permission was given to the defence to have the prisoner examined, but in the few hours at their disposal the defence were unable to obtain the services of a medical man specially trained in mental diseases. In spite of the Crown's refusal in the first instance to admit any reason for an examination of the prisoner, the Crown, at the last moment, and after the Judge's order was given, instructed a medical expert to report on the prisoner's condition. It is unfortunate that, apparently through either official incapacity or bias, the action of the prisoner's advisers should have been unnecessarily hampered, more especially in the case of a person eventually declared insane by the jury.

## Malaria and Mosquitoes.

AVERAN's famous discovery of the parasite of

malaria has ied to results of far-reaching importance. The disease has been enormously reduced in many parts of the world, and the tropics have been rendered habitable by the partial control of their greatest scourge. It was not until 1898 that Ross, reviving the theory of Lanciso, traced the spread of the infection to the agency of mosquitoes. Since then the work of practical prevention has gone on apace. It has been waged mainly, however, against the mosquitoes themselves, an almost hopeless task when their vast numbers and wide distribution are taken into consideration. Happily there are other ways of attacking the problem, and the latest method consists in immunising mankind rather than in seeking to exterminate the mosquitoes. The plan adopted is to use quinine as a prophylactic for healthy persons, and also to prevent recurrence in persons who have been attacked. The free distribution of quinine has been adopted in various parts of Italy, and some attention has been given to its administration in pleasant forms, especially the tannate, which is comparatively tasteless and tolerated by children. In addition to this measure, the nocturnal defence of habitations is also widely adopted. Remarkable results have been obtained in Italy by the use of these two simple expedients. On the authority of Professor Celli, it is stated that the mortality from malaria in that country has fallen from 21,033 in 1887 to 4,160 in 1907. At this rate we may expect that another generation will be able to look back upon malaria as a purely historical malady, just as we now regard plague and cholera in the United Kingdom.

# State-Aided Hospitals.

THE question of State aid for charitable hospitals crops up from time to time in various parts of the Kingdom. A correspondent of the Daily News points out that a precedent exists in Ireland for the existence of State-aided and State-controlled hospitals. In the Government estimates for the coming year he cites the heading "Non-effective and Charitable Services," which grants a sum of £17,000 in aid of nine hospitals and a female orphan house in Dublin. Out of the total amount  $f_{15,850}$  goes to the hospitals, which are under the supervision of a Board appointed by the Lord-Lieutenant, who reports to Parliament annually upon their condition. The same writer gives the following account of the origin of these annual grants:-When the Irish Parliament was in existence, all the Dublin hospitals but one were in receipt of State aid. The Act of Union provided that the aid should be continued for twenty years, the idea being that at the end of that period Dublin would require no further help. But this belief was not justified, and as a result the grants were continued from year to year. In 1856 an Act of Parliament was passed fixing the amount and making it permanent. As this system is reported to work admirably, it affords a precedent worthy of careful consideration.

# Speed Limits and Medical Men.

CERTAIN privileges have been claimed from time immemorial in the case of the rights of medical men visiting patients to take short cuts over private property. The precise legal conditions of the

latitude thrus claimed have never, perhaps, been exactly defined, but the belief in its existence is, nevertheless, deeply rooted in the popular belief. The point has been raised in a somewhat different form in relation to Hyde Park. During the London season, as many people know, Hyde Park is closed to petrol-driven motors during three hours of the afternoon. Last week, in the Commons, Captain Craig asked the First Commissioner of Works whether he would consider the advisability in the public interest of altering the regulations regarding the Royal parks in order to permit members of the medical profession to pass through during the prohibited hours in motor-cars, whether petrol or electric driven; and whether special permits for this purpose could be issued. To this Mr. L. V. Harcourt replied that Hyde Park is the only Royal park closed to petrol-driven motors during three hours of the afternoon for the three months May to July. As the speed of motors in the parks is limited to ten miles, whilst the street limit is twenty miles, members of the medical profession in a hurry to reach their patients and to avoid penalties would be well advised during these and all other months to avoid the parks and stick to the streets. This answer hardly appears to meet the case fairly and squarely, and certainly will not strengthen the case of those who assume the right of reserving a public possession for the exclusive enjoyment of a particular class of society.

# The Board of Education and Medical Inspection.

THE recently-issued Report of the Board of Education for 1907-08 contains an important general statement upon the subject of the medical inspection of school children. In view of the crucial point as to the scope of the examination and the special qualifications of the examiner, the official statement of opinion will no doubt be closely scrutinised. The Board report that their experience since January 1st, 1908, when Section 13 of the Education (Administrative Provisions) Act, 1907, came into force, has confirmed their belief in the soundness of its principles. They realise that their application must vary in different localities and that many practical problems can only be solved by experience; but they are convinced of the soundness of the general lines laid down in their first memorandum (issued in November, 1907). With reference to the model schedule (issued in February, 1908) the Board remarks:—"The schedule was purposely made comprehensive and its apparently detailed character is not inconsistent with the statement that the inspection of a child should not on the average take more than a few mniutes. The experience of those local education authorities who have made substantial progress with the work has confirmed the Board's opinion in this respect." To the average medical man this allowance of time will hardly appear adequate. The Board hope to issue a special report shortly which will give detailed information as to the steps taken by the various local authorities in this important matter since the passing of the Act.

# PERSONAL.

The Queen has appointed Lord Frederick Fitz-Gerald, Lady Gormanston, and Mrs. Charles Martin (Dublin) to be members of the Council of Queen Victoria's Jubilee Institute for Nurses, the extension of the work in Ireland having rendered it desirable that the Irish branch of the Institute should have further representation on the Council.

WE understand that H.R.H. Princess Louise (Duchess, of, Arguil) will open in Liverpool on May tath: an International Congress on District Nursing, in which she takes so much interest.

THE Harveian Oration of the Harveian Society will be delivered by Mr. A. J. Pepper, F.R.C.S., to-morrow, at 8.30 p.m. His subject is: ""Thirty Years' Hospital Experience and Practice."

Dr. Edward D. Madge has been decorated by the King of Roumania with the Order of the Star of Roumania.

Dr. H. R. HUTTON has been appointed I ecturer on Diseases of Children at Manchester Royal Infirmary in succession to the late Dr. Ashby.

THE French Government has conferred the Legion of Honour upon Dr. F. S. Leclercq, an English physician, of Carlsbad.

MRS. GARRETT ANDERSON, M.D., Mayor of Aldeburg, was last week entertained at breakfast at the Midland Hotel by the Manchester Association of Registered Medical Women.

THE thirty-first ordinary general meeting of the Home Hospitals Association for Paying Patients will be held at Fitzroy House, Fitzroy Square, I.ondon, W., on Friday next, at 4 p.m., his Grace the Duke of Northumberland, K.G., in the chair.

THE National League for Physical Education and Improvement will hold a meeting at 137 Harley Street, W., by permission of Mrs. Bickerton, to-day, at 3.30 p.m. Mrs. Carl Meyer will take the chair, and an address will be delivered by Dr. F. E. Fremantle, county medical officer and school medical officer for Herts.

LORD NORTHCOTE will preside at the annual festival dinner of King's College Hospital, at the Hotel Cecil on Monday, June 21st. The Committee for the removal of the Hospital to Scuth London has received a further donation of  $f_{c1,000}$  from Messrs. W. H. Smith and Son in aid of the fund.

The Annual Court of Governors of the Seamen's Hospital Society was held on March 11th, under the presidency of Mr. Perceval A. Nairne, Chairman of the Committee. Sir Walter Hunt-Grubbe, Sir Stephen Mackenzie, Dr. T. L. Rogers, and Dr. Thomas Secombe, R.N., were elected Vice-Presidents, and Mr. E. Iydekker, Capt. E. B. Pusey, R.N., General the Hon. Sir Reginald Talbot, K.C.B., and Mr. John T. Wimble, members of the Committee of Management.

SIR ALFRED JONES, chairman of the Liverpool School of Tropical Medicine, telegraphed to Prince Auguste d'Arenberg, President of the Suez Canal Company, his congratulations on the honour paid to the Prince by King Edward, who recently decorated him with the Order of Grand Commander of the Star of India. A letter sent on behalf of the School coveyed congratulations to the Prince on the honour bestowed upon him, and also expressed appreciation of the support they so long received from him and also from the company.

In the Isle of Wight Mr. Charles Dabell, C.C., presided at a meeting of the committee appointed to promote the Island memorial to the late Dr. Groves, Medical Officer of Health for the Island, it having been suggested that according as funds permitted the memorial should take the form of a bed, a cot, or some other addition to the County Hospital, with which the late Dr. Groves was so long associated. The Chairman stated that the fund raised was well over \$300, and that after meeting the expenses incurred so far, some \$£295\$ odd was available for the memorial.

# A CLINICAL LECTURE

# TERTIARY SYPHILIS IN UPPER AIR PASSAGES.

By HORACE LAW, M.D.,

Throat Surgeon to the Adelaide Hospital, Dublin.

Our subject for to-day is some of the commoner forms of tertiary syphilis in the region of the upper air passages, &c. I do not propose to make this a complete résumé of the subject, but rather to take up some of the cases I have lately seen and discuss them. Before doing so, however, it is well that we should understand what we mean by tertiary syphilis and what are its main forms as usually seen, and which affect the region we are about to deal with.

As is well known, syphilis is divided into two main forms; the acquired, and the hereditary. The former, being divided into primary, which is at the seat of infection or relating thereto, and the secondary, in which the disease takes the general form and manifests itself all over the body, and the tertiary, where the disease has ceased to be systemic, but lights up in local inflammations from causes which are not well understood. It is generally considered that no tertiary symptom is seen until a full year has passed by from the time of inoculation; but, on the other hand, many years may elapse before these signs develop, or the patient may escape them altogether. It is often laid down that this recrudescence of the disease, if it may be so called, is due to a lowered power of resistance in the system and debility; of course, also the fact of whether treatment in the early stage has been efficient or not, is of great importance. It is sometimes stated that those cases which in their onset appear most mild may, after years of immunity, show serious lesions, most often in the nerves or brain; here also it is possible that the mildness of the original attack may have conduced to inefficient treatment, and that this may be the explanation of these cases. The forms of tertiary syphilis which come within the range of our subject are :-

- 1. Forms of ulceration of the mucous membrane, and a superficial inflammation causing silvery patches, the latter most often seen on the tongue.
- 2. Gummata; these are soft tumours composed of small-celled infiltration, which go through the stages of deposit, death due to want of blood-supply from the rapidity of their growth, and finally discharge.
  - 3. Ostitis, with caries and necrosis.

Case 1.—Man, act. about 50. He came to me complaining of very foetid discharge from his mouth in the region of the premaxilla, and pain and tenderness on trying to eat. Marked nasal trouble was absent. On examination, at first sight the line of teeth seemed complete, but on closer examination this proved to be a sequestrum of dead bone fairly loose, which had dropped down until it reached the lower edge of the teeth on either side of it. The hard palate showed a deep V-shaped ulcer, with dead bone as its floor. The sequestrum was gripped with a strong forceps and removed. When it was examined it was found to correspond accurately with the bone called premaxilla, or with that part of the upper maxilla which developes from an anterior centre. The interest in the case lies in the fact that the demarcation line of the necrosis is found to correspond with the developmental structure, and it may be looked upon as an ostitis followed by necrosis.

Case 2.—Man, æt. 30. He came to me complaining of a large red swelling over the pomum adami, which, on palpation, fluctuated. The borders of the swelling were hard and circumscribed, there was a slight pain on swallowing, but the main trouble was the external swelling. He was advised to go into hospital; after some delay he did this and the abscess was opened externally; a large quantity of pus was evacuated and a little air whistled out; this showed that the abscess had also opened internally into the larynx. Treatment consisted of boracic poultices and iodide of potash combined with mercury. Healing was rapid and no sequestrum formed, nor was there any gross change to be seen in the larynx. This was a case of perichondritis on the external surface of the thyroid cartilage, which broke down and formed an abscess, and, owing to the delay, had time to find its way internally into the air passages as well as externally, fortunately without causing necrosis of a large portion of the cartilage.

Case 3.--Girl, æt. 15. She came, complaining of nasal discharge of a horribly foetid character. After a little cleaning up, a large sequestrum, composed of the vomer, was removed, and on the next visit some more pieces were taken away. It was now possible to see that the whole septum from back to front was gone, except a small bridge of skin anteriorly. Treatment by iodide of potash and mercury in large doses was ordered, but was not carried out efficiently, with the result that three weeks afterwards the remaining bridge of skin was gone; every effort was made to persuade her to submit to treatment in vain, and a redness and sinking-in of the nose was noticed at her last visit. In this case we have the same disease manifesting a more malignant nature, not because it is essentially different in form, but owing to poor treatment, and probably lowered resisting power, possibly coupled with a severer infection.

Case 4.—Girl, zet. 12. A small, delicate-looking child, came with a large deep ulcer elongated antero-posteriorily, and showing a sequestrum in its floor. Two large pieces were removed which opened up the nasal cavity, and they proved to be pieces of the palate bone, the vomer apparently escaping in this case. The medicinal treatment was the same as above. These two last cases are of peculiar interest, as the origin of infection is open to doubt. Are they cases of hereditary disease, or of ordinary infection? If the latter, were they infected at birth, as babies, or later on? I could not extract any history worth recording, nor could I find any satisfectory evidence of true hereditary syphilis, so that I am obliged to conclude that they were infected since birth. All the above cases show the disease in a severe form.

Case 5.-Man, æt. about 50. He came to me complaining of a sore throat and pain on swallow-

The first glance into the throat showed a small ulcer on the free edge of the soft palate, whose characteristics partook rather of secondary syphilis than anything else, except for the fact that it was unilateral. No syphilitic history could be obtained, but, taking all the symptoms into consideration, it was diagnosed as a tertiary ulcer and treated by local applications of nitrate of silver, and iodide of potash internally; this rapidly produced a cure, and the patient disappeared for nearly a year; on his return he complained that his former symptoms were much worse, and examination showed a large uneven ulcer with ragged edges in the same position as the former one, but the larger part on the nasal surface of the palate and marked thickening all round it, which extended into the pillars of the fauces and over to the uvula and a little on to the posterior wall of the pharnyx. The case was taken into hospital, and microscopic examination confirmed the diagnosis of carcinoma. This case shows a not uncommon sequence, namely, the occurrence of carcinomata in old syphilitic scars. In the early stage this affection behaved much as the usual syphilitic ulcers do, and it was watched right on until no disease was seen or felt, and the subsequent appearance of cancer was not expected, though it could have been dealt with if the patient had returned when the recurrence of his symptoms began.

The milder forms, which are more commonly seen, consist of small gummata, situated in various parts, for instance, the soft palate, the posterior pillar of the fauces, the posterior wall of the pharynx, the naso-pharynx, or the septum of the nose. In all these the appearances are much the same, a punched-out ulcer with red, thickened and everted edges. The floor of the ulcer is a dirty grey colour, and unhealthy, the shape circular or serpentine if two or three separate gummata coalesce, often perforating in the palate, anterior pillar of the fauces, or nasal septum.

#### DIFFERENTIAL DIAGNOSIS

- 1. Of slight ulceration from secondary syphilis, tubercular or lupoid ulceration. The less severe forms of tertiary ulceration are in their inception, probably, occasioned by the coalescence of several small gummata, which have formed superficially, and therefore should not be regarded as different from the severer forms, where there is no doubt as to the gummatous origin. They may, however, be mistaken for secondary ulceration unless the symmetry of the latter is borne in mind, and the other secondary signs looked for; however, the secondary form is much more superficial, and does not show the loss of tissue which is a prominent feature of the tertiary. Lupoid ulceration has also to be considered, and here the same characteristics hold as in the form of the disease in the skin. It is nodular or granular, not neeply punched out; in fact the floor is often raised above the level of the surrounding mucous membrane, and the raw ham colour is often reproduced, especially on the palate.
- 2. Severe ulceration from tubercular and cancerous Gummata need to be diagnosed from tubercular ulceration and carcinoma, when we remember that the coalescence of tubercles makes a tuberculoma, which is essentially a granuloma, and also, that a gumma is a granuloma differing but little in structure, we realise the necessity of accurate observations. Strictly stated, the tuberculoma grows slowly, and does not cut off its own blood supply so quickly, and, therefore, as we would expect, we find a rapid breaking down of

the gumma into an ulcer with a dirty grey floor, thickened edges, and a punched-out appearance, owing to a loss of tissue, whereas in the tubercular form the surface is eroded away and leaves underneath a granular ulcer, whose edges are thickened and everted, but whose floor oftentimes is now below the level of the surrounding healthy tissue, and, indeed, may be above it. Finally, the chronicity of the tubercular and the rapid improvement of the syphilitic under iodide of potash will render the diagnosis clear. In the case of cancer, the difficulty of a quick decision is great, and, at the same time, admits of no delay. fashioned plan of allowing iodide of potash to decide is not advisable, if a shorter way can be found. It is not possible to lay down absolutely the characters, and often the best plan is to remove a piece for microscopic examination, though if the cancer is a recent one early operation is the right course, without waiting for anything. The many points of difference lie more in degree than in form; both are stinking ulcers, both have everted edges, but the carcinoma has generally more infiltration and hardness around it, and the glands show more enlargement. As mentioned in Case 5, the two diseases may be found together in the same patient, though not generally active at the same time, the tumour formation being superimposed on to, or arising in, the cicatrix of the former lesion.

3. Specific for simple periostitis. This is generally diagnosed by exclusion, by the history of syphilis, or by the advancement of the disease to

the next stage—that of necrosis.

- 4. Syphilitic necrosis from tubercular or simple. Is it possible to diagnose syphilitic necrosis from that due to injury or tubercle? I think so, and often from its naked-eye appearance alone. In the two latter forms above-mentioned, if necrosis takes place an abscess forms, and then, when it reaches the surface, a sinus results; while in the syphilitic form, the inflammation spreads to the soft tissues, and results in a large open sore with dead bone at the bottom.
- 5. Perforations in the nasal septum are of three kinds—simple, tubercular, or syphilitic. It is laid down—correctly, I believe—that the simple form is confined to the cartilaginous portion, while the other two extend further, and also that the syphilitic tends to attack the vomer, this being rarely or never the case in the tubercular form. Perforation of the palate is nearly always syphilitic, though lupus may eat away a portion of the posterior edge. A few cases of permanent perforation of the anterior pillar of the fauces or soft palate have been recorded, due to severe ulceration during scarlet fever.

### TREATMENT.

Local treatment, consisting of a mild mercurial wash, about a teaspoonful of black wash to two ounces of warm water for the nose or nasal pharynx, and about twice as strong for the mouth or pharynx. In the latter situations, calomel may be puffed on to the ulcer in the sublimed form, and acts very quickly. Touching the ulcer with silver nitrate is also useful, especially on the pharyngeal wall. General treatment may also be summed up in the words "iodide of potash"; but mercury is useful in the severer forms, especially if there is reason to believe that treatment in the early stages is incomplete. Treatment by injection will hardly be necessary in this stage. For the relief of pain, orthoform powder may be applied freely, or a gargle with opium in it may be prescribed, and, if cicatrisation should take place, injection with fibrolysin has been used with marked benefit.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for west week will be by Prof. A. Calcot, M.D., Physician to the Berek Institution, Paris. Subject: "Treatment of Local Tuberculous Lesions by Injections."

### ORIGINAL PAPERS.

### THE DIFFERENTIAL DIAGNOSIS AND INOCULATION TREATMENT OF TUBERCULOUS GLANDS IN THE NECK. (a)

By L. C. PEEL RITCHIE, CH.M., M.D., Research Student, Surgical Department, University of Edinburgh.

THE matter under discussion, although familiar, is yet by no means exhausted, and I propose to deal specially with an aspect of it which, as the subject of recent work, may present certain features of novelty. The diagnosis of tuberculous glands in the neck from other affections presents little difficulty in the great majority of instances. The question of suitable treatment often demands the greater consideration. A notable revival of the employment of tuberculin in the treatment of tuberculous conditions has been seen in recent years in this country. Allowing for the enthusiastic reports inevitably attending such a revival, it will probably be admitted that the results of tuberculin treatment in surgical tuberculosis are in no way amazingly successful, and are not infrequently unsatisfactory and even disappointing. Such has been my experience in a number of cases, while, on the other hand, steady, if slow, improvement to recovery, and with, perhaps, avoidance for the patient of the discomforts of operation, has been the gratifying course of events. Such conflicting results in patients similarly affected and similarly treated early attracted my attention. At first all my tuberculous cases were treated with Koch's Tuberculin R., which is prepared from bacilli of human type and origin. If, then, some of the patients were infected with bacilli of bovine or other type, it was conceivable that these were the cases which failed to respond satisfactorily to the inoculations. I therefore endeavoured to determine whether blood examinations devised to this end would serve to clear up the difficulty.

Since I first, in 1907, reported on some preliminary experiments, describing a method which served to show that the phagocytic blood reactions of tuberculous individuals might vary essentially in character, I have investigated this point much more fully along different lines. Put shortly, my conclusions amount to this that, in blood tests by means of the phagocytic index (the so-called opsonic index), using tubercle bacilli of distinctive characters, of human type and origin, and of bovine type and origin respectively, one finds that the sera of tuberculous patients show the various diagnostic reactions, some to the one type, some to the other. So far I do not happen to have met a case which gave positive reactions to both, nor any unquestionably tuberculous case which gave a negative reaction to both types. Further, inoculation of tuberculin made from the one type of bacilli affects the phagocytic index to that same type only. My deductions from this are that the blood changes in patients infected with tubercle are not all of the same character, but show certain differences, which can be readily ascertained by various applications of the phagocytic index tests such as I shall presently describe, and that these differences may be taken as indicating whether the patient is infected with the human or the bovine type of bacterium. This observation would, however, have but academic interest, for we are still far from knowing what significance phagocytosis may really have in the development of immunity to tubercle, were it not that clinical experience has shown that the laboratory tests point the way to the proper form of tuberculin treatment. By

(a) Bead before the Chelsea Clinical Society at the Annual Clinical Debate, March 9th, 1909.

that I mean that the case found to be infected with the human type of bacilli should be treated with tuberculin prepared from the human type, that infected with the bovine type with tuberculin prepared from the bovine type.

It is an interesting fact that a number of cases that I have treated myself, or which have later come under my notice, having been given inoculations of what I should now consider an inappropriate form of tuberculin, have shown a degree of improvement at first which was attributed or thought to be attributable to the tuberculin. The relapse, often severe, occurring subsequently, demonstrated that no real immunisation had been obtained. It is quite a possibility, nevertheless, that tuberculin of one type may have a partial immunising action for infections of the other type.

immunising action for infections of the other type.

Such unfortunate relapses in the absence of explanation would naturally give rise to distrust in tuberculin treatment, and I think reports on the results of this form of treatment should be reconsidered in the light of this differentiation of types. Where unexpected relapse in the course of treatment with human tuberculin has occurred in my earlier cases, it has been found that the initial diagnostic test to the human bacillary type had been negative, and regarded as possibly a technical error, whereas subsequent examination, when carried out, has shown the case to be really one of bovine infection.

As a preliminary, then, to a satisfactory course of specific inoculation treatment, three diagnostic tests are available. Two of these have already been reported on, so I shall but briefly refer to them here.

Firstly, the Inoculation test, devised by Struthers Stewart (a), which consists in giving ac injection of .002 mgrm. of tuberculin for an adult patient. On testing the blood at the time of inoculation and 24 and 48 hours after, it is found that a negative phase ensues in an infected person, but not otherwise. This reaction is apparently a specific one—that is to say, if a patient is infected with bovine tubercle, the inoculation of bovine tuberculin alone produces a negative phase, and that only in the tests with bovine bacilli, and vice versa. To make a test complete, it would be necessary toinject both types of tuberculin and test the indices to both types of bacilli. It has the disadvantage of upsetting for the time being the state of the blood should any further examination be desired, and also, for our purpose, of requiring a somewhat larger dose to be given than that with which one may care to commence a course of treatment.

Secondly, there is an Absorption test, which I have now used extensively, which gives very definite results, and is also specific in character. It consists in diluting the serum with a thick suspension of an indifferent organism. This has the effect of absorbing from all sera the non-specific substances which produce phagocytosis, while leaving the specific substances, the result of infection, to act on the corresponding bacteria when these are added to the phagocytic mixture. The normal serum used as a control, having no such specific substances, shows a reduced phagocytosis, whereas the infected serum still produces a high degree of phagocytosis of the infecting organism. As I have gone into the details of the test elsewhere (b), I shall not trouble

you further with them at present.

Thirdly, there is a test, simple in principle and application, which has been largely occupying my attention of late. I may call it the Comparative Index test. It is based on a considerable number of observations which I have made to the effect that, as against the same control, the phagocytic index of an infected person's serum is the same, within the limits of technical error, to all organisms other than the one with which he is infected. The index to that organism usually stands at a distinctly different level, whether higher or lower. It may on occasion happen to approach the same level if fluctuating, but this is, in my experience, but a rare eventuality. Instead of testing with a number of organisms, one may greatly simplify matters by testing with one indifferent

<sup>(</sup>a) Stewart and Ritchie, Edin. Mad. Jonen., May, 1907.
(b) Ritchie, Brit. Med. Jonen., Nov. 16 h, vol. ii, 1907.

crganism—that is to say, with which one may be certain the patient is not infected. This furnishes us with the patient's standard index, and it is compared with the indices to organisms suspected as the cause of infection. In tuberculous cases I would then test the patient's indices to avian, bovine, and human tubercle bacilli. The index to the avian bacillus gives the standard, and one may expect one of the other indices to correspond; the remaining variable index points to the type of infection.

This last test is, on the whole, the simplest and quickest, and, for our purpose, the most convenient, and it may be repeated at any time if desired for confirmation. It demands every attention to excluding variations from technical error, and may be less distinctive than the two other methods already mentioned.

These tests, then, furnish us, I believe; with a means of differential diagnosis with a view to inoculation treatment in cases of tuberculous glands in the neck. At the same time, of course, they provide a means of the glands and other conditions, provided there be ro other known tuberculous lesion elsewhere which might of itself give rise to the blood changes. For this general diagnosis, as has been indicated, no phagocytic index test is complete unless both types of bacilli are taken into account.

The question naturally arises here whether the cases present clinical features distinguishing them in correspondence with the results of these blood examinations. With a view to this paper I have collected my records of cases to date in the hope of gleaning some information on this point. I find that out of about 200 cases of surgical tubercle examined, there are 37 cases of glands in the neck whose records afford sufficient information to bring before your notice in this connection. In three of these cases the cervical glands were not a predominant feature in the tuberculous infection, being at the time either quiescent or having been previously removed by operation, were not causing further trouble.

Of the 37 cases, 22 were judged to be instances of human infection, 15 of bovine infection. Taking up the features in detail, first, as regards age incidence, reckoning on the ages as far as ascertainable at which the glands were first noticed. If we take 18 years as dividing those who have attained to puberty from the remainder, we find that, of the human type, 11 were 18 years and over, 11 were under that age, while of the bovine type only 4 were of 18 years and over, and 11 were under. Taking 21 years as the attainment of maturity, we find of the human type 6 cases occurring over that age, of the bovine type only 1. In such a limited number of cases numerical computations are somewhat erratic, but the general conclusion is, 1 think, justified that the bovine type is rare after maturity, and, on the whole, is more characteristically an infection of youth than is the human type.

As regards sex incidence, we find that the human type is more frequent in each sex, but disproportionately so to a slight degree in the male sex. Next as regards the occurrence of complications of a tuberculous nature elsewhere than in the cervical glands, five-sixths of the human type, and four-sixths of the bovine type present such complications. These numbers are not, then, suggestive, though the nature of the complications may be and is worth some study. I cannot enter fully into this at present, but would only point out that bone and lung affections represent the bulk of the complications in the human type, glandular, skin, and eye affections in the bovine type. As for the family history, it is a matter of regret that my information has often been incomplete. I have been surprised, however, to find how seldom a history of tubercle was obtained, and the interesting observation remains that in the only three instances in which I have got definite particulars of gland tubercle in the family the affections have been of the bovine type, and in the only two instances obtained of phthisis in the family the affections have been of the human type. Case No. 7 is interesting in this respect. The patient, æt. 22, first suffered from tuberculous glands in infancy, and the father died of phthisis when she was two years old.

Next, with regard to the duration of the disease in the glands, no very definite conclusions can be drawn from a list of cases first seen at various periods of their illness. An accurate estimate can only be made from cases after final recovery. It may be mentioned that, though their total number is fewer, more of the bovine cases gave a history of over one year's duration. This may be taken as meaning that, on the whole, there were more acutely developing cases of the human type requiring attention, and that more of the bovine type had been left to a hoped-for spontaneous recovery. I can also record that this corresponds to the general impression I have now formed that the bovine type of surgical tubercle tends to be of a slow, chronic character, often intractably persistent, while the human type is frequently associated with the more acute forms of disease. But this is by no means exclusively the case.

The occurrence of liquefaction in the glands, or the persistence of discharging sinuses after operation, affords a more definite subject for consideration. As far as these records permit it, we find that these features developed more frequently in the bovine than in the human cases in the proportion of 4 to 3. Of course, the possible occurrence of secondary infection may influence this estimate. It is, however, further suggestive of the idea that the bovine affections furnish the more persistent chronic cases.

It is apparent from this review that while the clinical features of the two types may have certain special tendencies or characteristics, these are not yet definitely enough ascertained to permit of a differential diagnosis being made with any feeling of surety on these clinical This may be a possibility in some, grounds alone. though not in all cases, in the future, when more numerous and representative data are available. It is certainly difficult to decide what constitutes a representative series of cases. For instance, a children's hospital would conceivably supply a greater proportion of bovine cases than appears on my list. Again, the great majority of private cases of surgical tubercle which I have examined are of bovine type. Then, too, my list is influenced by the considerable number of adult cases, probably subjects of early phthisis, cases appearing at the surgical out-patient department of a large general hospital (the Royal Infirmary of Edinburgh). One may surmise that, while hospital patients and those of the better classes are almost equally exposed to food infection, those of the better classes are much less frequently exposed to and also better guarded against infection from phthisical individuals. The frequency of the human type of infection among hospital cases may thus be explained, and it is interesting to note that many of these cases are noted as factory workers, miners, and plumbers. It is also a possibility to be kept in view that the types of cases may vary in different localities.

At present, then, one must regretfully admit the necessity of falling back upon the methods of blood examination to determine the appropriate tuberculin treatment. First of all, then, in this connection, the technique of administration demands a word or two. The most suitable tuberculin, in my opinion, is Koch's Tuberculin R., and this is now to be obtained commercially made from either human or bovine types of bacilli as may be desired. I recommend diluting the tuberculin as sent out with .9 per cent. sterilised saline. Glycerine should not be used This is filled into small sterile flasks fitted with rubber stoppers. A few drops of chloroform are added, and renewed as evaporation takes place. The chloroform, on being shaken up, partly passes into solution and serves to maintain the sterility of the fluid indefinitely. The most suitable dilutions depend on the dosage to be given, and for the comfort of the patient it is desirable to inject the smallest quantity of fluid that can be accurately measured in the syringe. The injections should be made with a syringe accurately marked, which can be sterilised by boiling, and is fitted with thin I in. platinum needles. As accuracy of dosage is of such

prime importance, it is desirable to work with the metric system and to use a syringe marked in divisions of I cubic certimetre, and I may mention that syringes made abroad and marked in minim measure are frequently very inaccurately calibrated. The injection should be made directly into the substance of a muscle. I find that the middle of the triceps in its lower fourth, or in children the gluteus, are the most convenient sites, but any other suitable mass of muscle may be chosen. Following this technique I have never found any trouble resulting.

As regards the dosage, there are certain general principles which need to be observed to avoid possible causes of ill-success. First, the more acute and active the development of the disease, the smaller should be the dosage. The smaller the dose the shorter is the duration of its action. There is nothing to be gained in the end by an attempt at rapid immunisation. initial doses should be given at comparatively short intervals to avoid the production of a condition of hyper-susceptibility. For the same reason no dose should be smaller than any preceding one. If a dose given is thought to be too large, it should not be diminished, but a longer interval than otherwise is allowed to elapse before the next is given On the other hand, it is probably not necessary to increase to any extent a suitable dose. As the condition becomes quiescent, and passes under control, the interval may be lengthened and the dose slightly increased. The ideal dosage is, to my mind, that which, without causing any obvious reaction, produces the most pro-longed effect. The doses must be steadily continued, not given at hap-hazard, and treatment should never be started unless its continuance has been arranged for.

Following out these principles in the treatment of a chronic case of tuberculous glands in the neck in an adult, one would give a dose of .oot milligram of the appropriate tuberculin; repeat the same dose in two weeks, then in three weeks, and then at successive intervals of four weeks. After at least six months or more had elapsed, one might then, if the case had progressed satisfactorily, extend the interval to five or six weeks, and increase the dose by a quarter or a half to .00125 or .0015 mgrm., and continue with this to the end of treatment. Under these circumstances there is no necessity of giving the patient a "rest" from the inoculations.

In a strictly chronic case such a course as this will manifest its results in a slow but steady improvement, without any effects being directly noticeable from the injections. If the condition, however, is active or progressive, such a dosage may give rise to an increase of inflammation at the seat of disease, so if a gland is already breaking down, the liquefaction may be augmented by collection of serum and the abscess point more rapidly at the surface. In many cases this is inevitable when the disintegration has occurred to any appreciable degree, but, at any rate, it is desirable to proceed more cautiously at first. Accordingly, the initial dose should be a half or a quarter of that mentioned, depending on the acuteness of the disease. The second dose is given after a week or ten days, the subsequent doses at intervals of three weeks, and, if progress is satisfactory, these doses are increased till, after, perhaps, two or three months' treatment, dosage falls into line with that described for quiescent condition.

The doses stated are those for an adult. For younger people they must be proportionately diminished, and one would accordingly do well to give three-quarters the amount to a patient under 20 years, half the amount to one under 14, and so on. An infant would get onetenth or one-twelfth.

These doses, as I should mention to avoid confusion, are based on the original and correct calculation of Koch's Tuberculin R., as sent out, containing the active properties of 10 milligrams' weight of bacteria per 1 c.cm.

We have now to consider the results of treatment on these lines in the various conditions of glandular tubercle as they present themselves to us, for the course of events is largely dependent on the actual state of the glands at the time when treatment is commenced. If tuberculous glands are treated in the earliest stages the result should be particularly satisfactory. have been reported in which glands have rapidly disappeared after actually but one or two injections of tuberculin. I have not myself seen any such case, and I have considerable doubt as to the possibility of tubercle having been the cause of the enlargement. A tuberculous infiltration is not to be so simply and rapidly resolved, while from the practical point of view we must recognise that before tuberculous glands draw any attention to their condition, the degree of infiltration and involvement is already extensive, and caseation in all likelihood has taken place in at least some of them. It is this caseation that is the stumbling-block in recovery, for though extension of the disease is readily enough controlled, the removal of the caseous material is probably not specially aided, and is only attained after a considerable lapse of time, while it may long continue to harbour bacilli still capable of development should opportunity offer. In caseous glands, then, one must look forward to a prolonged course of treatment to ensure recovery.

If periadenitis is present, one finds that it shows rapid improvement, and after two or three injections, a mass of glands, at first indefinite in outline, becomes altered so that the individual glands can be readily felt. I have several times seen it stated in print that the beneficial effect of tuberculin injections is to render the glands softer and smaller. This seems to me toindicate either an incorrect diagnosis or a misconception of the pathological processes taking place, and of the aims of treatment. A tuberculous gland, unless calcified, is already soft and succulent, and may be caseous or semi-fluid from liquefaction. In the process of natural recovery which tuberculin only further aids, the gland loses its inflammatory exudation, shrinks, becomes smaller and firmer, and, when healing is complete, abnormally hard and fibrous. If a gland, then, under treatment becomes softer, one may anticipate that liquefaction is occurring, but in this case the gland increases in size. As I have mentioned, the inoculations may seem to bring about this condition, but my impression is that they only hasten a process-which has already commenced. It is not, indeed, an altogether undesirable incident, though, to avoid distrust, it is well to warn the patient of what may happen. If the accumulation is near the surface, it may be removed by puncture with a trocar, and this may require to be repeated if the cavity is a large one, or a small drainage tube may be inserted temporarily. As the re-accumulated fluid is usually for the most part serous, the administration of calcium salts deserves trial in order to diminish the amount of exudation. The outcome is often very favourable, as a large collection of tuberculous material is removed much morerapidly than could have taken place by absorption, and only a hardly visible puncture scar remains. In any case the tuberculin treatment should not be interrupted.

If, however, the patient does not come under observation till the skin is already itself infiltrated and thinned, surgical measures must, of course, be considered with a view to avoiding ulceration and disfigurement. In the presence of sinuses or secondary infection due to the presence of pyogenic organisms, inoculation treatment against this may, with advan-

tage, be combined with the tuberculin.

If tuberculin treatment is to be relied upon, onemust be prepared to carry out the inoculations for a minimum period of six months in the most favourable cases, and, as it should be made a rule in tuberculousdisease to continue the injections for a considerabletime after the obvious signs have gone, one may count on the advisability of treatment for a year. In cases where extensive caseous deposits have already formed, still longer treatment is probably necessary. To judge of progress, one must neglect day-to-day variations, which are often considerable in caseous glands, and decide rather whether from month to month there is, on the whole, a steady improvement and diminution in the size of the glands.

Such prolonged treatment may seem burdensome and

a tax on the patience of the invalid and the medical attendant. Following such a scheme of inoculations as I have mentioned, however, it is not really so, as the injections are given at considerable intervals, and by routine, and do not necessitate constant supervision of their immediate effects. It should be quite possible, therefore, to give hospital patients attending even a busy out-patient department the benefit of tuberculin therapy on these lines. It should not be adopted, how-ever, in patients ill-cared-for or insufficiently nourished. The usual medical treatment of a tonic The usual medical treatment of a tonic nature may, with advantage, be combined in the attempt to assist the natural powers of recovery, and I would specially emphasise the enormous benefit derived from transferring town children to the country, if only even for a short change. Of local methods of treatment I would but refer to the application of heat, which, in theory, at any rate, should be beneficial.

This is most conveniently carried out by the use of small, flat sandbags, heated as hot as can be comfortably borne, and applied to the neck at night when the patient retires to bed.

While I have dealt here specially with inoculation treatment, I should not wish it to be thought that I am opposed to operative measures, or even consider the two methods of procedure antagonistic. They can, in fact, well be combined. The attractiveness of attaining by mechanical removal within a few days a result for which natural processes demand as many months is undoubtedly great. But, with regard to operations in tubercle, there are two features to which special attention should be drawn. In the first place, there is the great probability that tuberculous infection is more widely distributed throughout a patient's body than is evident on the surface, or discoverable by the means at our command. Enlarged glands in the neck may be, therefore, but the outrop, so to speak, of a stratum of hidden glandular tubercle. A radical operation in the neck, therefore, even if that term is really justifiable, may be radical only in a local sense. To perform such an operation on a patient extensively affected is to speculate freely on their powers of resistance to the disease. In the second place, there is the further pro-bability that operative interference in a tuberculous area may readily lead to a dissemination of the bacteria to other parts of the body as well as that operated on. This is, perhaps, specially likely to result from a curetting operation, but may occur under any circumstances in which tuberculous foci are laid bare. are comparatively few operations in which tuberculous lesions can be removed in toto by cutting only through healthy tissues, and this is not probably the case in gland operations. That this possibility of spread of the disease by operation is a notable one I am firmly convinced. I do not refer merely to those cases of meningitis and acute miliary tuberculosis ending in death occasionally occurring in consequence of operations, which are already recognised as they could hardly fail to be! I refer rather to cases of localised infection occurring at a distance, it may be, or close at hand, which, as with most tuberculous lesions taking some time for their development, are less likely to be attributed to the preceding operation. Such patients one hears spoken of as having tubercle in their "system," so that they are always developing some fresh trouble. They bulk very largely among the cases of multiple surgical tuberculosis which crowd the out-patient departments of our hospitals. I have so constantly found that each new appearance of disease was a sequence of a shortly preceding operation that the only conclusion feasible was that the two incidents were interdependent.

Looking upon tuberculin treatment as having little effect on caseous deposit of tubercle, and therefore of chief value as a prophylactic measure which guards against extension, I should be inclined to recommend that, unless abscess formation already existing demands immediate attention, operative procedures should be deferred, if permissible, till a course of tuberculin treatment has been initiated. As experience has shown that one or two inoculations are insufficient to protect against extension after operation, the patient should

be treated for a period of, say, at least six months. The question of operation may then be reconsidered. Possibly a radical removal may not be called for. Whether or no, the surgeon may expect to find the condition of the glands much more favourable for operation than formerly, and he is taking less risk as to the possible prejudicial results of interference. For the reasons already stated, the inoculations should be continued till recovery is finally ensured.

#### ON THE

# EARLY DIAGNOSIS AND SURGICAL TREATMENT OF CANCER OF THE STOMACH. (a)

By D'ARCY POWER, M.A., M.B.Oxon., F.R.C.S.Eng.

Surgeon to, and Lecturer on Surgery at, St. Bartholomew's Hospital; Consulting Surgeon to the Victoria Hospital for Children.

I have been looking through the notes of cases of cancer of the stomach which have been under my care, and it is clear that in hospital practice patients are not treated until late in the disease, whilst in private practice those who prove to be suffering from cancer of the stomach are not willing to be treated for anything more than indigestion, until bleeding or the discovery of an abdominal tumour gives clear evidence of the nature of the mischief.

The early symptoms of cancer of the stomach are identical with those of the chronic ulceration to which I believe it is nearly always secondary, just as epithelioma of the lip is secondary to the chronic irritation caused by a foul pipe, or cancer of the tongue to the changes produced previously by syphilis. Cancer of the stomach usually developes very slowly, and is localised for a long time to the part of the stomach where it begins. Secondary growths are not the rule, and even where the lymphatic glands are enlarged in the immediate neighbourhood of the stomach, microscopical examination in several cases has not shown the existence of any epithelial deposits, but only the hypertrophy of chronic irritation. In all my cases of cancer of the stomach the patient was over thirty years of age, and was usually between fifty and seventy. Men and women were affected nearly equally.

I do not believe that at the present time we have any means of diagnosing cancer of the stomach with even approximate accuracy by means of the symptoms, for the same symptoms are produced by any ulceration of the stomach, whether the cause is innocent or malignant. The signs are more helpful. A test meal is serviceable both on the microscopical and chemical sides. It is not sufficient merely to estimate the amount of free hydrochloric acid on a single occasion, but the estimation should be repeated more than once. Dr. George Graham has gone farther than this in some of our recent cases of cancer of the stomach at St. Bartholomew's Hospital, for he has estimated the organic hydrochloric acid present, but as yet without obtaining any very helpful facts. In other cases I have had skiagraphs taken of the stomach after the mucous membrane had been rendered impermeable to X-rays by a coating of oxycarbonate of bismuth. The result is satisfactory in the case which I show you of advanced carcinoma, but in the early stages we were unable

<sup>(</sup>a) Contribution to a discussion at the Harveian Society, March 4th, 1909. See page 301.

to detect any localised thickening. It seems, therefore, that we are driven to actual inspection if an early and certain diagnosis is to be made, and, even then, we must beware of mistaking an innocent thickening in the pyloric region such as is produced by a duodenal ulcer for a mass of carcinoma. I do not mean by this that every case of chronic indigestion with some loss of flesh should be submitted to an abdominal operation, but that every case where there is grave suspicion should be explored, permission being obtained to remove the growth if a microscopical examination by a skilled pathologist made whilst the abdomen is open proves the mass to be carcinomatous. The farther operation would consist of a partial gastrectomy with a posterior gastro-enterostomy, an operation which is well borne by patients.

The prophylaxis of cancer of the stomach rests with those who see the patients in the earlier stages and long before they come to ask advice of a surgeon. Irritation, as is well known, not only leads to cancer, but increases the rapidity of its growth. It is of the first importance therefore in cancer of the stomach to put the organ at rest, both on the physiological and on the anatomical side. Physiologically by allowing proper food to pass into the stomach in a condition which is best fitted for its gastric digestion; anatomically, when physiological means have failed to afford relief, by exploring the stomach, removing any actual disease which may be removable as early as possible, and by performing a gastro-enter-ostomy to put the stomach at rest where this operation seems advisable. It is, I think, a very great mistake to allow a chronic ulceration of the stomach to continue indefinitely, the symptoms being masked by the administration of bismuth and carminatives until cicatrisation and the formation of an hour-glass stomach is produced. It savours too much of the old plan of keeping wounds open to heal by granulation instead of allowing them to repair by first intention. By all means allow Nature to heal by her own processes, but as soon as these show themselves insufficient to bring about a cure the surgeon ought to interfere, and the occurrence of cancer of the stomach will then become rarer instead of more frequent, as is the case at present. My treatment consists in resort to a good dentist, diet, and if necessary partial gastrectomy and gastro-enterostomy. It ought to be a reproach to doctor and patient alike to have a history of dyspepsia lasting for six, eight or ten years with intervals of improvement when the patient is put to bed, followed by renewed pain when she returns to her ordinary habits. It should, how-ever, be clearly understood that the surgeon cannot cure in every case, and that he must be guided by the signs and carefully weigh each history. The term "chronic gastric ulcer" is at the present time purely clinical, and very similar symptoms are presented by several different classes of gastric disease.

Officers of the Indian Medical Service on the active: list have subscribed a fund to found a prize in memory of the late Sir Joseph Fayrer, to be awarded at each half-yearly examination to the lieutenant on probation I.M.S. who obtains the highest number of marks in the subject of pathology at the conclusion of the course at the Royal Army Medical College. The prize will consist of a medal, with, in addition, a gift of books, should the proceeds of the fund permit. THE

### EARLY DIAGNOSIS OF CANCER OF THE STOMACH. (a)

BY ARTHUR F. HERTZ, M.A., M.D.Oxon., M.R.C.P.:

Assistant Physician to Guy's Hospital.

I SHALL confine my remarks to two methods of diagnosis of cancer of the stomach, which have been comparatively recently introduced, and which promise to be of considerable value in aiding us to diagnose the condition in its earliest stages, when there is still a possibility of radical

cure by operation.

The first method is the examination of the stools for "occult blood." Hæmorrhage from a gastric growth is rarely sufficient to give rise to obvious melæna, and blood is visible in the vomit of less than 40 per cent. of cases kept under observation until the fatal termination. As in the majority of instances hæmorrhage severe enough to cause obvious hæmatemesis is a comparatively late symptom, and as its occurrence, even in the form of the so-called "coffeegrounds vomit," may with equal probability be a result of a simple gastric ulcer, the obvious presence of blood in the vomit or the stools is of very little help in the early diagnosis of cancer of the stomach. But minute hæmorrhages are constantly occurring from the surface of every malignant gastric ulcer, so that a small quantity of blood is constantly excreted in the fæces. This fact was first utilised as a means of diagnosis by Ewald, and numerous papers on the subject have since been published abroad, but, so far as I am aware, only one-by Dr. Leech, of Manchester-in England. Chemical tests for occult blood in the fæces are much more satisfactory than microscopical or spectroscopic: the best are the guaiacum and the benzidene reactions made with ethereal extracts of stools, which have first been treated with glacial acetic acid. The test is more satisfactory when applied to the stools than to the vomit, as it is necessary to make a series of examinations, and vomiting may not be of sufficiently regular occurrence for this to be possible. There is also no advantage to be gained by looking for occult blood in the gastric contents obtained by the passage of a tube, and it is undesirable to worry the patient by passing a tube more frequently than is absolutely necessary. The test for traces of blood in the fæces is so delicate that the small quantity present after meat has been eaten may give a positive reaction. It is therefore advisable to put the patient on to a farinaceous or milk diet for a few days prior to the first examination. This diet has an additional advantage, as it helps to distinguish between a malignant and a simple gastric ulcer. Slight oozing of blood frequently occurs from the surface of chronic non-malignant gastric ulcers; but with a non-irritating diet, the hæmorrhage quickly ceases, whereas in the case of a growth the hæmorrhage is quite unaffected. No less than 92 per cent. of 266 recorded cases of gastric carcinoma gave a positive reaction, although it was rare for the microscopic appearance of the stool to suggest that blood was present. The blood was found in all, or nearly all, of the specimens of fæces examined in each case. On

<sup>(</sup>a) Contribution to a discussion at the Harveian Society, March 4th, 1909. See page 301.

the other hand, in no single case of gastritis, nervous dyspepsia or pernicious anæmia, has the test for occult blood in the stools been positive. Apart from the occurrence of obvious hæmatemesis and melæna, traces of blood are frequently found with gastric and duodenal ulcer, but in a much smaller proportion of cases than with cancer; moreover, under dietetic treatment, the blood always disappears in two or three days if the ulcer is simple in nature, but never if it is malignant. Hence the constant presence of occult blood in the stools of a suspicious case is strong confirmatory evidence that cancer is present, and its constant absence is even stronger evidence against the diagnosis of a malignant ulcer. Of course many of the published cases were examined in the late stages of the disease. Perhaps Mr. Moynihan and other surgeons here this evening can tell us from their operative experience on very early cancer of the stomach, in what proportion of such cases ulceration is present, as it is only after ulceration has occurred that a positive reaction for occult blood can be expected. In the large number of cases of cancer, which are due to malignant changes occurring in a chronic ulcer, the test would certainly be positive from the first moment that the cancer begins to develop. When the growth forms independently of any previous gastric disease, some time must, of course elapse before ulceration occurs, but I think that in such cases it will be found that ulceration begins at a very early stage.

The second method of diagnosis to which I wish to refer is skiagraphy. Unfortunately the results obtained by the X-rays in the diagnosis of really early cases have, up to now, been of less value than might have been anticipated. Occasionally, however, a clue is given to the correct diagnosis at a very early stage before a tumour has become palpable, so that I am convinced that in every doubtful case an X-ray examination

should be made.

Skiagraphy has been chiefly employed with the object of finding the size of the stomach and the rate with which it gets rid of its contents, and thus obtaining evidence as to the existence of pyloric obstruction. My own experience, however, shows that, though the X-rays may give valuable help in other ways, they do not give as reliable information on these points as certain older methods of examination. In an investigation on the normal anatomy of the stomach, Dr. C. J. Morton and I found in seventeen normal young men remarkable differences in its size and shape. In the vertical position the greater curvature always reached below the umbilicus, the distance varying between 1 and 12 cms. Normal variations being so considerable it is impossible in the vertical position to recognise a slight dilitation by means of the X-rays. In the horizontal position, the bismuth tends to collect in the fundus, so that the position of the greater curvature is often difficult to ascertain. On the other hand, inflation of the stomach with carbon dioxide produced by the action of tartaric acid on sodium bicarbonate, the two substances being swallowed in water rapidly after each other, or with air introduced by a tube passed with the object of obtaining the remnants of a test-meal, gives constant results in normal individuals, the greater curvature being invariably on a level with, or slightly above, the umbilicus. Very slight dilatations are therefore readily recognised, as the

greater curvature reaches below the umbilicus. On rare occasions, moreover, the inflation may cause a tumour previously impalpable to become palpable. It very rarely causes any discomfort, and although the distension it produces is obviously not physiological, it gives definite results which can be compared with a definite normal standard. I may here mention that my X-ray investigations have shown conclusively that both direct percussion and auscultatory percussion are quite unreliable as means of determining the size of the stomach, except when it has been inflated with gas.

With regard to the rate at which the stomach empties it must be remembered that even if there is considerable obstruction to the pylorus, fluids, if given alone, can pass through it without much difficulty. Hence it is an error to assume that obstruction is absent if fluid, in which a bismuth salt is suspended, is seen to leave the stomach rapidly after its entry. For such examinations a proper bismuth meal, containing solids as well as fluids should be given. It has also been supposed that a shadow present in the region of the stomach six hours after a bismuth meal indicates that there is delay in the passage of food into the duodenum. But I am convinced that traces of bismuth may remain adherent to the gastric mucous membrane for a considerable period after all the food has left the stomach. In my opinion, therefore, no conclusion can be drawn from X-ray examinations as to delay in the evacuation of the gastric contents which can compare in reliability with the results obtained by passing a tube at 8 a.m. into the stomach of a patient whose last meal was dinner taken at 8 p.m. the previous evening. The presence of food residues in the stomach under such conditions is almost conclusive evidence of organic stricture of the pylorus, as it is exceedingly rare for an atonic stomach to be unable to empty itself completely in twelve hours.

.The value of X-ray examinations as an aid to the early diagnosis of cancer of the stomach, depends almost entirely on the opportunity they occasionally afford for direct observation of abnormalities in the shape and movements of the organ. The patient should take a pint of bread and milk containing two ounces of bismuth oxychloride instead of breakfast, and he should be watched in the vertical position with the screen whilst the first few mouthfuls are eaten, in case any delay occurs in the passage of food through the cardia, which would be suggestive of a growth in this situation, or any irregularity is noticed in the course taken by the food as it slowly passes towards the pylorus. When all the bread and milk has been taken the patient should lie for a minute on his right side, so that some of the bismuth may enter the pyloric vestibule, after which he should lie on his back during the screen examination. Occasionally an abnormality in the outline of the stomach is caused by the projection of a growth into the lumen. In other cases the pyloric vestibule cannot be seen whatever position is assumed, as a growth in this region may prevent the entry of more than a very small quantity of the gastric contents. Equally valuable evidence of the existence of a growth is obtained if an irregularity is seen in the passage of the peristaltic waves towards the pylorus. When the growth is in the pyloric vestibule the waves, which may be unusually

strong and frequent, often cease some distance from the pylorus, owing apparently to the growth interfering with the normal activity of the muscular coat of the stomach. It is advisable before concluding the examination to inject air into the colon; this pushes the stomach upwards, but at the same time it makes the outline of the greater curvature more definite, and occasionally makes it possible to recognise the presence of a tumour, which would otherwise have been missed.

# THE MEDICAL EXAMINATION OF SCHOOL CHILDREN. (a)

By GEORGE CARPENTER, M.D.,

Physician to the Queen's Hospital for Children, Vice-President of the Royal Society of Medicine, &c.

DR. CARPENTER said that the Board of Education, in its Circular numbered 582, dated January 23rd, 1908, addressed to local education authorities on the subject of medical inspection of school children, refrained from issuing a complete set of forms, thinking it expedient to leave considerable latitude in regard to the particular forms or schedules. A schedule of medical inspection, together with elaborate notes for inspecting officer, was, however, issued wherein the Board of Education indicate the particulars, attention to which they regard as constituting the minimum of efficient medical inspection. Dr. Carpenter expressed the opinion that the Board of Education, in refraining from issuing definite forms, intended to allow the local authorities to incur any odium attaching to this official work; in other words, the local medical inspector of the schools, who would perform the rôle of Jonah should a storm arise. The feelings or prejudices of parents have to be considered, according to the statement of the Board. These feelings and prejudices hamper the medical man in the performance of his duties, and mark him out for popular sacrifice, to escape which he was entitled to official sanctuary. The schedule of medical inspection set forth by the Board was impracticable and unpractical, and to make it workable a practical chinical chart had to be designed. Dr. Carpenter pointed out the far-reaching nature of the indications in the notes for inspecting officer accompanying the schedule of medical inspection, copies of which were provided at the meeting, and described how, to facilitate medical in-spection in a London suburb whose local education authorities had engaged him to examine some hundreds of their school children, he drew up a practical form comprising all the requirements contained in the Board of Education Circular (No. 582) to local education authorities. Dr. Carpenter's form was also placed in the hands of members of the section. Dr. Carpenter then described the method which he had adopted in inspecting the children. They were undressed, wrapped in a blanket, placed on a couch, and a thorough medical inspection was made in the best room that could be obtained at the particular school for the purpose. In many instances the parents were present, and in all cases one of the schoolmasters; or schoolmistresses. Dr. Carpenter then read extracts from the letters he had received objecting to the medical examination. The chief objection appeared to be that to the examination for the presence of adenoids, and one parent stated that the same rug or blanket in which the child was wrapped was usel for each and every child.

(a) Paper introducing discussion at the Rayal Society of Medicine Feb. 26th, 1999.

In response to the letter from the clerk of the local. Education authority in reference to parents' complaints, the Board of Education arranged for the representative of the local education authority toattend at the Board of Education to discuss the matter. Dr. Carpenter, however, not being notified. until the morning of the interview, was unable toattend. The Board of Education appeared to-consider that to undress children for the purpose of medical inspection was superfluous and unnecessary, and that the heart could be easily auscultated by exposing a small cutaneous area over the left nipple. The quaint instruction that a child could be pronounced healthy by looking at it was also upheld. Dr. Carpenter went on to say that it wasobvious that if the medical examiner did his duty and examined properly, if the parents objected, he need expect neither support nor encouragement from the local education authority, nor from the Board of Education. If, on the other hand, he did not perform his duties properly, his functions are parasitic rather than medical, and he becomes an extra and unnecessary burden on the rates and the taxpayer. What medical man is there who understands his profession, and who knows the business, who can pronounce by looking at a child whether it is healthy or not? If these be really the well-considered views of the Board of Education, then the sooner it is instructed by men whohave had clinical experience the better for the country. If we are to have medical inspection of elementary school children, let it not be a sham. The information demanded by the Board of Education in its Circular No. 582 could not be obtained by any such antiquated methods. Dr. Carpenter then read notes of the various deformities, defects, and diseases which he had found in his examination of 552 presumably healthy elementary school children of a London suburb, who were undressed and properly examined. Over 200 had. rickety deformities in varying degrees. In 367 the teeth were carious, with a total of 1,514 carious teeth, an average of 4 per girl and 4½ per boy-The tonsile were enlarged in 119, 129 there were adenoids, the naso-pharynx. in 34 being completely blocked by growth. In 181 the deep cervical glands were enlarged, in 172 the sub-maxillary, and in 337 the superficial cervical; 29 children had bronchitis, 1 pneumonia, and I cirrhosis of one lung with a transposed heart. This last child looked particularly well and had rosy cheeks, and under the quaint instructions of the Board of Education would have been excluded from any searching examination. Of skin complaints 2. had xerodermia, 1 psoriasis, and 7 pediculi corporis. These defects were discovered by examining their skins, and not by looking at their waistcoats and pinafores. To many examiners of school children who take a pride in their work, the class of men the Board of Education ought to enlist, it is a matter of vital interest to know how much support they will receive in their arduous duties from the people who have set them their task. If the Board of Education's "Notes for Inspecting Officer," the minimum of efficient medical inspection as laid down by the Board are not intended to be taken seriously, then let the Board modify or withdraw them, because as they stand they compel a conscientious medical inspector to make a thorough examination in every case. The legislature, when it ordered medical inspection, at the same time authorised attention to the health and physical condition of the children. Before there can be treatment there must be diagnosis, and diagnosismust be preceded by medical examination. present instructions to local education authorities. by the Board of Education on the way to conduct a medical inspection can only be viewed as an illadvised encouragement to medical inspectors of elementary school children to pocket the fees and neglect the work, and so rob the Act of most of its value.

### OPERATING THEATRES.

PADDINGTON GREEN CHILDREN'S HOSPITAL. EMPYÆMA WITH ABDOMINAL SYMPTOMS.--MR. ARTHUR EDMUNDS operated on a boy, set. 5, for a small left-sided empyzema. The boy had been sent in a week previously with a history of an acute onset of ab-dominal pain referred to the right iliac fossa. There had been vomiting on each of the days preceding his admission. The abdomen had been tender and rigid. On admission the child was found to have a temperature of 103°, and a pulse of 120. A diagnosis had been made of acute appendicitis. Although subsequent events proved that this diagnosis was inaccurate, Mr. Edmunds pointed out that there was much in the symptoms to suggest it—the acute onset, with symptoms of an acute infection, with vomiting and reference of pain to the right iliac fossa made up a picture which anyone might mistake for appendicitis.

Mr. Edmunds said that the first point noticed was that the respirations were out of all proportion to the temperature; they were 48; secondly, that the alæ nasi were acting very markedly. In all breathing, he remarked, there is the action of the ordinary respiratory muscles, but, in addition, there are associated movements of the alse nasi and larynx—that is to say, dilatation of the alse and rima glottidis, or abduction of the cords during inspiration and the reverse during expiration. These occur normally, but in some respiratory affections, especially when they involve an irritation of the parietal pleura, these are increased. The nasal movements are easily visible; the laryngeal are evidenced by a respiratory grunt, indicating the pas-sage from the stage in which the air is contained in the lungs under pressure from the contracting thorax to the stage when expiration takes place. When the child under consideration was quite quiet, respiration was without any noise, but directly the boy was moved about for examination, the expiratory grunt came on. In addition, the patient's facies did not suggest abdominal disease; there was entire absence of the anxious, haggard look, and sallow complexion these patients have, and the child was comparatively cheerful. On placing the hand on the abdomen, the whole abdomen felt rigid and board-like, but when the child was allowed to lie quietly in bed, the clothes pulled up over him, and the abdomen examined under the warm bed-clothes, gentle pressure soon revealed the fact that this rigidity was spurious. The abdomen could then be completely relaxed, and the whole of the iliac fossa explored. Careful questioning now elicited the fact that the child referred his pain to the umbilicus—in other words, his localisation was quite un-reliable. The alæ nasi and the respiratory condition generally suggested that a pulmonary affection might be at the root of the whole trouble. Careful examination of the lungs revealed an early pneumonia at the left base. The child was seen again the same evening in consultation with Dr. Leonard Guthrie, who was able to satisfy himself as to the definite nature of the pneumonia.

The relationship between abdominal symptoms and intra-thoracic disease should, Mr. Edmunds said, always be borne in mind. It may be dependent on one or two factors: In the first place, pulmonary affections may involve the diaphragm, in which case it is not difficult to see how the abdomen may seem to be largely involved; this is specially so when the pul-monary affection is confined to the portion of the lung which is actually in contact with the diaphragm; in fact, in these cases the pulmonary symptoms may be largely absent. In other cases the pulmonary affection may be only part of a general pneumococcic invasion, in which the peritoneum actually shares, but from which it rapidly recovers.

The pneumonia ran a normal course, but at the end of ten days fluid appeared at the left base, which on exploration turned out to be purulent. Accordingly, the child was anæsthetised, a rib resected, and drainage tube put in.

### TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

MEETING HELD FRIDAY, FEBRUARY 26TH, 1909.

Mr. SYDNEY STEPHENSON, F.R.C.S.Ed., in the Chair.

DR. HIGGS, on behalf of Dr. CAUTLEY, showed (1) a case of cerebral diplegic spasticity in a boy of six months, which came on with rigidity in the back and limbs, and retraction of the head, at the age of seven weeks. On admission to hospital three weeks ago, there was general rigidity, which varied from time to time, and would come on with spasms, with considerable crying. The boy improved on a mixture of bromide and chloral. Mr. Bishop Harman found the left disc unduly red, with a few pigment spots along the course of one vessel. The condition was ascribed to an attack of exceptability followed by corrected. to an attack of encephalitis, followed by cerebral! sclerosis of the motor region.

Mr. BISHOP HARMAN showed a sketch of the pigment

spots, which might be termed congenital warts.

(2) A boy, æt. 4½, suffering from abdominal tuberculosis. The abdomen was enlarged, with a band stretching across the upper part, giving the impression of a coiled-up and matted omentum, containing caseous matters. He had been treated with tuberculin. The opinion of members was asked on the advisability of attempting the removal of the caseous matter by surgical means, or on a continuance of the general

methods of treatment and larger doses of tuberculin.

Dr. Milner Burgess said that if the lungs were not

affected he would advise operation.

Dr. Higgs replied that, although there was no evidence of infection of the lungs, he thought the case should not be operated upon, as some of the masses-were probably due to inherent coils of intestine, and contained caseous glands. (3) A Mongolian imbecile, aged 7½ months. The case showed brachycephaly, a large fontanelle, palpebral apertures sloping upwards and outwards, inability to sit up, placidity and good nature.

Mr. Sydney Stephenson showed a child, æt. with a soft, doughy swelling situated over the right half of the vertical portion of the frontal bone, and extending into the right upper eyelid, and also into the temporal and parietal regions. It was adherent to the overlying skin, and a cord-like feeling can be made out in some parts of it. The child is said to have attended the Moorfields Hospital for buphthal mos, and was brought to hospital on January 21st with acute inflammatory cedema of the right upper eyelid. It was impossible to say for certain what the condition was, but he thought that it might be a plexiform neuroma, and hoped to excise a small portion of the tumour for microscopical examination.

Mr. W. M. Mollison (M.O.) showed a child, æt. 2,

Mr. W. M. Mollison (M.O.) showed a child, 2t. 2, with absent abdominal muscles. The abdomen was very pendulous, and the walls thin and lax, the abdominal walls being easily felt even when the child cried. The bowels kept regular, and there was no difficulty in micturition. No electrical response could be obtained from the abdominal wall. There did not appear to be any distension of the bladder or thickening of the ureters.

Dr. LANGMEAD said that there were about 18 cases on record. Usually there was much distension of the bladder and thickening of its walls, with palpable ureters. He believed that most of the cases had died in early infancy; the present one was an exception in that respect.

Mr. Lockhart Mummery showed (1) a child who had suffered from acute epiphysitis of the lower end of the femur at the age of 1 year and 7 months. After

operation the abscess cavity remained at the lower end of the diaphysis, which was scraped out, washed with strong formalin, and filled with sterilised paraffin wax, the wound being stitched up again. The general health of the patient was good, but a small sinus remained, from which a little clear fluid, and occasionally some of the wax, was discharged for about six months. It is now two years after the first operation, and there is no appreciable deformity of the bone or shortening of the limb, and X-ray photographs show that the cavity in the bone has almost disappeared. The incavity in the bone has almost disappeared. fection was a mixture of streptococci and staphylococci. (2) A case of talipes calcaneus treated by

splinting with a good result.

Dr. O. GRUNBAUM showed a case of Hirschsprung's disease, or chronic dilatation of the colon. A child, æt. 4, was admitted to hospital in August, 1908, for fits and constipation. The abdomen was enormously distended, the skin being tight, and the superficial veins prominent. On administering an enema an enormous result was obtained, and on repeating this at intervals the child returned to a normal condition. He has been re-admitted twice since with a similar condition. Improvement followed rapidly each time upon the administration of enemas. The risk of colectomy was so great that Dr. Grunbaum, having consulted with his surgical colleague, considered that so long as the child can be kept in a healthy condition with suitable treatment, no operation should be done.

Dr. G. A. SUTHERLAND said that all the cases he had seen had died. As the prognosis was so bad, and the patient was now in such a favourable condition,

it would be well to operate now.

Mr. LOCKHART MUMMERY said Dr. Sutherland spoke lightly of operation, but what operation should be done? The mortality of colectomy in a number of cases in this condition which he had collected was 75 per cent.; that was because one could not bring the bowel up and make a spur of the abdominal wall. All that could be done was to form a fæcal fistula at the dilated portion of the bowel, and in most cases the bowel had torn away from the abdominal wall and the patient had died of peritonitis. The only operation likely to give permanent results was the excision of the dilated portion of the colon. This was a serious proceeding, but, even if successful, the colon might become re-dilated. He quoted four cases in which this had occurred. In a case which had gone on to adult life, a man, æt. 23, he had done appendicostomy, the bowel being washed out daily. It was now six months since the operation, and the man had had no obstruction.

Dr. GEORGE CARPENTER opened a discussion on the MEDICAL EXAMINATION OF SCHOOL CHILDREN,

which will be found on page 208 of our present issue. Dr. Fremantle (M.O.H., Hertfordshire) said he approached the matter from a different standpoint to that of Dr. Carpenter. As County Medical Officer his work was to superintend the inspection of 47,000 school children in 33 sanitary districts. The work was actually done by medical practitioners who were engaged in clinical work, and were in touch with the conditions under which the children lived. The inspection was done three times during a school child's life. The Government in Britain went slowly, and the inspections might be more frequent later. reports were made on cards, 10 in. by 6 in., suitable for filing. The scheme drawn up by Dr. Carpenter for filing. The scheme drawn up by Dr. Carpenter could not be beaten for comprehensiveness, but, as a record, would not be worth having, unless the examiner were paid at least a guinea a child, to which he, as a ratepayer, would strongly object. That showed the fundamental difference between Dr. Carpenter's and his own points of view. The public were the ultimate masters, and the Government took the view that the matter must only be carried as far as the public wished. The point was to so carry out the inspection as not to arouse feelings which the inspector had no right to arouse. He thought the Circular 582 of the Board of Education was a masterly production. The remuneration was based upon an average rate of inspection of six per hour. Dr. Fremantle explained the system of marking the cards adopted in Hertford-

shire. He did not think the Section for the Study of Disease in Children ought to expect a large\_series of valuable statistics from the inspection. The main object of the inspection was the individual one. The Education Department wanted inspection, not examination. The object was not to detect the one in a thousand defective.

Mr. N. BISHOP HARMAN said that when he looked through Dr. Carpenter's schedule he felt admiration for Dr. Carpenter's energy, and thankfulness that he was no longer a school doctor. He doubted the capacity of a Medical Officer to fill up Dr. Carpenter's schedule. The object of the school inspection was to treat the diseases of children. Dr. Carpenter's mis-directed energy was due to the fact that he had spent a good deal of his life in the wards and out-patient departments of a children's hospital, where the children were necessarily diseased, and that fact of disease had become an obsession. The person of most use to the Medical Inspector was the teacher. What was chiefly wanted was a place to send children to as soon as it was discovered that they had something wrong with them. The object was not to find out what proportion of children had displaced hearts, nor what was the size of the inguinal rings. He believed the cry of degeneration was an extremist one.

Dr. G. E. SHUTTLEWORTH said his experience had been exclusively with children suffering from mental It was not easy to make up one's mind as to a child being healthy without going into some detailed examination. It was most important to decide whether the heart was sound, especially in view of the school drill and some drills in particular. He did not agree that the teacher could always give information as regards the hearing and sight. He had found children among the dullards at the back of the class who had been put there because they were considered below the standard, but who were found to be alert, though deaf, and should have been placed in front, where they could hear the teacher's voice. The same was true of defects of vision, and on those points there should be a systematic examination of every child in a school. One speaker well said that the whole question was the finding out of what children good could be done to. But what good could be done to children whose parents would not listen to the warnings of the medical inspector? There had been, apparently, some difficulty in conveying that warning without giving offence to the medical practitioner, but he hoped those matters would be adjusted in the course of time. If any medical inspector could do justice to the 24 questions on the Board of Education schedule with the marginal notes in ten minutes, he must be an extra-ordinary person. A good plan was to only examine a certain number at each visit.

Dr. W. EWART said that it stood to sense that mere inspection of a child could not give any idea of the state of its inside. By paying careful attention to the early stages and probabilities of tuberculosis, very much could be done towards preventing that disease.

Dr. Dan. McKenzie said no doubt all present would feel some sympathy with both the views which had been brought forward. For any benefit to be derived from medical examination it must be thorough. he believed it would be a long time before parents would submit their children to a proper examination, and the Board of Education document was as much as one could expect at present. He believed, how-ever, that Dr. Carpenter's speech would hasten a more perfect system. School *cliniques* in many parts of the country have much to recommend them, but in London and other large cities, containing many suitable institutions, they would be but waste of energy and time. There was only one way of examining for adenoids, namely, by putting the finger into the naso-pharynx. It was disagreeable and painful, and was sure to raise opposition. But the teacher would soon be able to report suspicious subjects of adenoids, and only a certain proportion of children would examined for them. The throat could be examined without pain.

Mr. Rose said that dental caries was very prevalent, 85 per cent. to 90 per cent. being subject to it. As dental surgeon the work of inspecting the mouth was not difficult. The requirements as to stopping or extraction should be carefully noted. Syphilitic teeth were not important in that connection because they

could not be treated.
Dr. CARPENTER briefly replied. He said Mr. Harman seemed to think that one could find out what was the matter with a child by looking at its waistcoat. He hoped Mr. Harman did not carry out this idea when examining eyes. His own schedule did exactly what the Board of Education required. The Examiner had only to "yes" or "no" under the various heads. After 20 years' experience, he declared he could not say whether a child was ill by looking at it as required by the order. What had brought about the present storm in a teacure was the brought about the present storm in a teacup was the digital examination of the naso-pharynx; it was not the undressing. Yet it must be fully realised what an avenue the tonsils were for various systemic diseases, and that it was not uncommon to have the cervical glands tuberculous from adenoids or enlarged tonsils. He was not putting himself in opposition to the Board of Education, but was supporting the examining medical men. His statistics bore out the impression that there was much rickets and general disease in the suburbs, and a good deal of it could be prevented through the Public Health Department.

### ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

MEETING HELD FRIDAY, MARCH 5TH, 1909.

The President, Dr. E. H. TWEEDY, in the Chair.

#### FIBRO-CYSTIC MYOMATOUS UTERUS.

DR. ALFRED SMITH exhibited a large fibro-cystic myomatous uterus taken from a patient, æt. 38, who informed him that she never felt any inconvenience up to some months before her admission to hospital, when she noticed she was getting rather stout. She was sent to him with a provisional diagnosis of ovarian cyst, and the clinical features were identical with the phenomena obtained in that condition. On opening the abdomen he thought he had to deal with an ovarian cyst, but to his astonishment he found a fibro-myoma which had undergone the degeneration seen in the specimen, giving a uniform pearly whiteness.

The PRESIDENT said the specimen illustrated the difficulty of gynæcological diagnosis. A big fibrocystic tumour was indistinguishable from ovarian cyst in a great number of cases. In examining per the rectum they could occasionally feel an ovarian pedicle, and if it was absolutely distinguished the diagnosis of ovarian cyst was made, but the absence was no proof

that they were not dealing with an ovarian cyst.

Dr. Smith, in reply, said he did not make any rectal examination, as the case seemed perfectly simple and straightforward.

UTERUS WITH LARGE CYST OF GAERTNER'S DUCT ATTACHED.

Dr. ALFRED SMITH exhibited also a uterus with large cyst of Gaertner's duct attached. Twelve years previously he removed what was called an ovarian cystoma from the other side of the patient. She afterwards complained of another enlargement. He opened to remove the cyst, and found that when he was dissecting it from the broad ligament it seemed to extend right down into the vagina. When he separated it as far as he could he found that the uterus had no support, and he removed it along with the cyst.

The PRESIDENT said he had operated on similar tumours, and had the greatest difficulty in enucleating them, as they not only went deeply into the pelvis and vagina, but climbed up under the peritoneum.

OBSTETRICAL AND GYNÆCOLOGICAL REPORTS OF THE ROTUNDA HOSPITAL.

The PRESIDENT read the obstetrical and gynæcological reports of the Rotunda Hospital.

On the proposal of Dr. ALFRED SMITH, seconded by Dr. NEILL, the discussion of the report was postponed till next meeting of the Section.

### HARVEIAN SOCIETY OF LONDON.

MEETING HELD (IN THE STAFFORD ROOMS) MARCH 4TH, 1969.

The President, Dr. CHARLES BUTTON, in the Chair.

A DISCUSSION ON THE EARLY DIAGNOSIS AND TREATMENT OF CANCER OF THE STOMACH.

Dr. HALE WHITE, who opened the discussion, said that one-half of all cases of cancer, as observed in the post-mortem room, commence in the stomach, and that one-fifth of all deaths in hospital die of cancer of the stomach. The cure must be surgical. To render this possible, an early diagnosis is imperative. The patient's history is of the greatest importance. Threefourths of all cases occur between 40 and 70. If symptoms of gastric indigestion first appear after 40, and if those symptoms are unaffected by ordinary medical treatment after 3 to 4 weeks, organic disease should be strongly suspected, and the abdomen should be opened. Nine per cent. of cancers, as observed post-mortem, grow from previous simple ulcers; but this figure is probably fallacious, because the carcinomatous growth may completely efface a previous ulcer. Dr. W. J. Mayo has observed about half of the cases of cancer, treated by operation, arising from simple ulceration. The history of previous ulcer may be fallacious, for the symptoms may be due to a non-ulcerous condition. An early diagnosis may be impossible, for the patient may first seek advice from enlargements due to secondary growths; this is not uncommon in secondary carcinoma of the liver. The commonest symptoms are as follows: Pain, present in 90 per cent. of all cases, is usually constant, and not related to food. Weakness is quickly experienced, and is more profound than in simple dyspepsia. Loss of appetite is a striking feature in carcinoma, but not in dyspepsia. Nausea occurs early. Free hydro-chloric acid is diminished in many cases of carcinoma of the stomach. In 10 per cent. of cases it is increased. This is said to occur especially in cases where the carcinoma has developed on the site of a previous-ulcer. The objection that the free hydrochloric acid is diminished by a carcinoma occurring anywhere in the body is unimportant, because malignant disease elsewhere is easily recognised by ordinary physical signs. Cases of atrophy of the gastric nucous membrane, and chronic gastritis, may diminish the free hydrochloric acid, but the diminution in these cases is less marked than in carcinoma. The presence of cancer cells or blood cells should be sought for in centrifugised washings of the stomach. In 35 to 40 per cent. of cases of carcinoma, the vomit at some time or another contains blood visible to the naked eye. In 60 per cent. of cases the growth occurs at the pylorus, and causes obstruction of the pylorus and dilatation of the stomach. Percussion without artificial distension and percussion are fallacious as signs, but examination with the X-rays with a screen, after a bismuth meal, is very useful. Delay in the passage of the bismuth through the pylorus can be seen; but the position of the bismuth shadow is not important, because the position of the stomach is very variable. Visible peristaltic contractions are valuable evidence of pyloric obstruction. No medical treatment can cure gastric carcinoma, hence the necessity for an early diagnosis, by which the surgeon can remove the growth. Before surgical treatment, the liver and left supra-clavicular glands should be examined for secondary growths. Even if the growth cannot be removed, much

relief can be given the patient by a gastro-enterostomy.

Mr. MOYNIHAN said that cases of cancer of the stomach, when examined in regard to their previous history, may be divided into three groups:—(a) Cases, generally acute, in which the symptoms appear sud-denly and progress rapidly; the whole history may be confined within a space of 4 to 9 months. (b) Cases in which there is a history of one ancient attack, or of repeated attacks, due undoubtedly to the presence of a chronic gastric ulcer. (c) Cases in which there is no previous history of gastric ulcer; in some of these a condition of "ulcus carcinomatosum" may be found. The acute cases are not seldom ushered in by an attack

of severe hæmatemesis, with or without melæna. It is possible that such copious bleeding is dependent upon multiple hæmorrhagic erosions. The importance upon multiple hæmorrhagic erosions. The importance of a history of repeated attacks of indigestion, alike in their origin, course, and termination, cannot be exaggerated. Such attacks are due to a chronic gastric ulcer, which at last becomes malignant. Cancer of the stomach, in so far as it depends upon a chronic ulcer for its origin, is a preventable disorder. It is probable that two-thirds of the whole number of cases may be so classed. The final attack is distinguished from former attacks by its lingering character, its rebellion against the treatment, dietetic and medicinal, which has proved helpful before, but chiefly by the presence of a profound distaste for food, anæmia, and a progressive loss of weight. The chemical examination of stomach contents is of little or no value in so far as early diagnosis of carcinoma of the stomach is concerned. In the later cases, when a pos-sible diagnosis of malignancy is made on the clinical evidence, the results of repeated chemical analyses of the stomach contents afford additional evidence of considerable value. Surgical treatment should be advised in all cases of stomach disorder where there is obstruction, stasis, or tumour, and in all cases of chronic ulcer; in this way early cases of carcinoma will be discovered, and radical treatment will surely be possible. There are no symptoms, and there are no signs, which individually or collectively permit of an assured diagnosis of cancer of the stomach in an early stage. In cases where there is grave suspicion an exploratory operation should be advised. Such operations should be practised to enable a diagnosis to be made in an early stage, not to confirm an almost certain diagnosis in a hopeless stage.

Dr. ROLLESTON said that it was obvious that under malignant disease of the stomach very different pathological and clinical conditions were included. the rare cases of the diffuse lympho-sarcoma of the stomach described by Salaman and others, in which the growth extended like a sheath along the alimentary canal, was a special form of new growth, possibly of infective origin, and from its method of spreading obviously unsuited for the radical treatment by excision, which, after all, was the important question for discussion. The more ordinary forms of malignant disease of the stomach fell into two main groups, which differed entirely, both in their clinical symptoms and as regards the possibility of cure by operation. These two groups were:—(1) Carcinoma of the cardiac end, and carcinoma of the pylorus; as a sub-division of this group the cases of carcinoma spreading from the pylorus and lesser curvature to the body of the stomach, and producing the leather-bottle stomach, might be included. In malignant disease of the cardiac end the symptoms were constitutional—namely, fever, anæmia, and debility, and might suggest tuberculosis, or infective endocarditis; whereas in carcinoma of the pylorus the symptoms localised the lesion to the stomach and commonly gave rise to mechanical effects. In carcinoma of the cardiac end the growth was rapid, was prone to necrose, to invade the adjacent left lobe of the liver, and set up diffuse suppuration in the adherent liver, and so to produce a condition most unsuitable for operative measures. He quoted cases of carcinoma of the cardiac end of the stomach resembling pulmonary tuberculosis; one patient with fever and intestinal hæmorrhage brought up material containing acid-fast bacilli, but the necropsy revealed a gan-grenous carcinoma containing acid-fast bacilli and no tuberculosis. The growth was so situated as to prevent any vomiting. In another case a gangrenous carcinoma produced a subphrenic abscess which in turn led to a left pleural effusion, which was the most obvious feature during life. In a woman admitted for anæmia and a tumour thought to be an enlarged spleen, skiagraphy, in the hands of Dr. Allpress Simmons, showed that the tumour was the stomach, with very thick walls, and a cavity 3 in. long by 1 in. broad. In cases of carcinoma of the pyloric end, it was important to make a diagnosis before a tumour was palpable, as in many instances metastasis had already occurred by the time that a tumour was manifest. In cases of prolonged gastric ulcer the tentative diagnosis was more easily made, even before the stage of tumour, by the absence of hydrochloric acid from the gastric juice, than in cases without any history of ulcer. In a patient with symptoms strongly suggesting gastric carcinoma, in whom a test meal showed an absence of hydrochloric acid in the gastric juice, exploratory laparotomy was justified to settle the question in the absence of tumour. When such an exploratory operation was undertaken, it was important that the surgeon should, in the event of carcinoma being found without obvious metastasis, proceed to partial excision of the stomach, and not lest content with gastro-enterostomy, which was a purely palliative course.

Mr. V. WAREEN LOW remarked that he came to the

meeting, not with the intention of making any contribution to the discussion, but in the hope of learning, and had not been disappointed. He had learned many things, but he certainly had not learnt how to make an early diagnosis of cancer of the stomach. As far as he could gather from the remarks of the openers of the discussion, Dr. Hale White appeared to rely chiefly on a careful analysis of the symptoms, such as pain, increasing ill-health, etc. No doubt, in the hands of such an experienced and careful observer as Dr. Hale White, this method, utilised in a large number of cases, would probably lead to a fair percentage of success, but he (the speaker) was afraid it would leave a considerable degree of uncertainty in the individual case, and particularly in that class of case so well described by Mr. Moynihan, in which the patient had suffered from stomach symptoms all his life. On the other hand, Mr. Moynihan apparently made the diag-nosis in the laboratory some days after the removal of a large portion of the patient's stomach. From the surgeon's point of view, or that of the mere seeker after truth, there could be no question that this was the best method. Whether it was so also from the patient's point of view was open to question. Partial gastrectomy, even in Mr. Moynihan's experienced hands, gave a mortality of 5 per cent. Gastro-enterostomy for simple ulcer had practically no mortality even in the hands of surgeons, who were practically tyros in stomach surgery. It was in everyone's knowledge that constantly cases occurred where even the most experienced surgeons had been deceived at an operation by the similarity of an old ulcer to a malignant growth. Dr. Rolleston had already mentioned such a case, and he (the speaker) recollected an instance where, in 1898, an anterior gastro-enterostomy was performed at St. Mary's for what appeared to everyone to have been a hopeless case of stomach cancer. This patient was alive and well two or three years ago. What would have been his chances had the operation been a partial The speaker was disappointed to find gastrectomy? that so little reliance was placed by gentlemen of such experience in gastric diagnosis on the chemical analysis of the contents of the stomach. As far as the speaker's own experience had gone, he had learnt to rely very largely on the expert examination of the stomach con-tents. His own cases had been examined for him by Dr. Willcox, and in the later cases, extending over a period of more than a year, this method in Dr. Willcox's hands had rarely failed him. He did not wish to say more, because he should like to hear what Dr. Willcox himself had to say on the subject. He concluded by thanking the openers of the discussion for their very interesting papers on this most

important subject.

Mr. T. Crisp English said that the important early signs of cancer of the stomach should be given a more prominent place in text-books on medicine and surgery. Too much space was usually devoted to the "classical" signs, and patients suffering from the classical signs were usually in a hopeless condition. He referred to the difficulty which sometimes occurs during an operation in diagnosing a chronic ulcer from cancer, even after careful inspection through an opening in the stomach. If the possibility of a radical operation arises, the diagnosis must first be certain. His own practice in such cases had been to excise a portion of the diseased area for microscopical examination, and then to do a gastro-jejunostomy; if the excised portion proved malignant, a partial gastrectomy was performed later. He fully agreed with Dr.

Rolleston's remarks as to radical operations, and he urged the more frequent performance of partial gastrectomy in preference to the palliative operation of gastrojejunostomy.

THE OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

MEETING HELD IN THE ROOMS OF THE MEDICAL SOCIETY OF LONDON ON THURSDAY, MARCH 11TH, 1909.

The Vice-President, Mr. W. H. H. JESSOP, F.R.C.S., in the Chair.

DR. G. CARPENTER showed a post-mortem specimen illustrating oxycephaly, and Mr. Sydney Stephenson mentioned a similar case which he had had, commenting on the shallow orbit and the consequent ease of dislocation of the eyeball.

Mr. J. Rowan showed some fine stereoscopic colour photographs, by the Lumière process, of eye con-

Dr. EDRIDGE-GREEN exhibited a new form of lantern

for the detection of detects of colour vision.

Mr. Parsons showed a case of unilateral optic neuritis with white spots in the retina; and it provoked a long discussion, in which the Chairman, Mr. Nettleship, Dr. F. E. Batten, and Mr. Bishop Harman

Mr. JESSOP showed a case of keratitis punctata, with

a history of erythema nodosum.

Mr. MAYOU and Dr. L. GUTHRIE showed a case of optic atrophy (retro-bulbar) with cerebellar symptoms in a child.

Mr. E. TREACHER COLLINS read a paper on

CONGENITAL ANTERIOR STAPHYLOMA.

The author described the case of a child born with an opaque, vascular, staphylomatous cornea, who never had any discharge from the eye. When 15 months old he performed a Mules' evisceration upon it, and subsequently made a pathological examination of the elliptical piece removed from the front of the eye. It was found that Descemet's membrane and the ligamentum pectinatum were absent, there was no stroma to the iris, and the lens was also malformed. Most cases of congenital anterior staphyloma have been attributed to intra-uterine ulceration. Mr. Collins thought that a case in which there was complete absence of Descemet's membrane and the ligamentum pectinatum could not be accounted for by ulceration, and must be attributed to some developmental defect. He suggested that there had been a failure in the differentiation of the mesoblast which intrudes between the lens vesicle and the surface epiblast, into its several layers. Normally there developed from it the substantia propria of the cornea, Descemet's membrane, its lining endothelium, and the antero-fibrovascular sheath of the lens. From this latter the feetal lens largely received its nutrient supply and the stroma of the iris was to a great extent formed.

A failure in the differentiation of the several structures, or atypical development of the intruding mesoblast, might, as in the case under consideration, lead to a vascularised, thickened, fibrous mass, in place of the substantia propria, an absence of Descemet's membrane, of the stroma of the iris, and a malformed lens. He concluded by referring to several other congenitally malformed eyes, in which he had found defects in development of Descemet's membrane or the ligamentum pectinatum of a less extensive character.

The paper was discussed by Mr. Parsons and Mr. G. Coats, who failed to agree with all that Mr. Collins

had advanced.

Mr. E. NETTLESHIP contributed seven new pedigrees of hereditary cataract: (1) Twenty-four cases of lamellar cataract in four generations; (2) and (3) coraliform cataract, one of them containing 20 cases, in four generations; (4) (5) (6) and (7) pedigrees of senile and presentle (or juvenile) cataract in from two to four generations, some of them illustrating "anticipation," i.e., the occurrence of disease at an earlier age in the younger generation. Two of the pedigrees showed the introduction of a second heritable disease from an outside non-cataractous stock, goftre in one instance, insanity in the other.

Dr. F. W. EDRIDGE-GREEN and Mr. C. DEVEREUX MARSHALL submitted a paper on SO-CALLED ARTIFICIALLY PRODUCED TEMPORARY COLOUR-BLINDNESS.

They stated that Professor Burch, of Oxford, had read a paper before the Royal Society, which was published in the "Philosophical Transactions" in 1898, giving the results of his experiments, in which he split up direct solar light with a spectroscope, and then collected the rays of the individual colours with a convex lens, and saturated his own eye with any deconvex lens, and saturated his own eye with any desired colour. He then examined a spectroscope illuminated with diffuse daylight, and stated his results. He found that he could produce temporary colour-blindness to any colour in this way. His most important point was that by saturation with light at the "D" line, red and green blindness supervened, and these colours could not be perceived, and this he held to support the complex nature of yellow light, the Young-Helmholtz theory of colour-perception. Messrs. Edridge-Green and Marshall criticised his experiments. They thought that if direct sunlight were focussed in the retina, not only temporary, but probably perma-nent blindness might be produced, and, anyhow, the eye would be incapable, after much treatment, of making accurate observations on a feebly-illuminated They produced fatigue in their own eyes with a sodium light, and then found that yellow and orange became obliterated, and that red and green met in the spectrum, and that there was no diminution of those two colours. Other experiments were repeated with different colours, and in most of them they disagreed with Professor Burch's results, which, they held, were due to faulty methods of conducting the experiments. These facts are, they contend, only explicable on the psycophysical theory of colour vision (Edridge-Green's theory).

### CORRESPONDENCE.

#### From our special correspondents ABROAD.

GERMANY. Berlin, March 21st, 1909

At the Verein für Innere Medizin Hr. F. M. Groedel (Bad-Nauheim), spoke on Röntgen cinematography (with demonstrations) and its importance in internal medicine. He said that the involuntary movements of internal organs could not be shown by ordinary X-ray illumination, as the eye could not follow the rapid movements. An attempt had been made to remedy this by giving the combined movements. But this method could be looked upon only as a pis aller, as only a voluntary combination could be given. We first succeeded in giving good Röntgen given. We first succeeded in giving sood according illustrations when we were in a position to reduce the time of taking to the fraction of a second. The speaker had succeeded in getting an apparatus constructed which could be brought to the body within a few seconds, whilst at every change the Röntgen light could be shut off. By this means he was able to take all internal movements correctly, those of the heart, the stomach during digestion, and the diaphragm. It was also possible to demonstrate pathological internal movements in the same manner. (The movements of the heart and diaphragm were now shown on the screen.)

Hr. Levy Dorn said he believed he was the first to make cinematographic illustrations of the human sub-The cinematogrammes introduced by Macintyre in 1806 were only of small objects (the frog's thigh). After Macintyre, other similar Röntgenogrammes were shown, for instance, the movements of the frog's stomach.

The first attempts to demonstrate human organs cinematographically consisted in trying to take the fluorescent images with the ordinary cinematograph. This led, however, to no useful result. It was therefore something new when he Röntgenographed human organs in their individual movements. The representation of movement was only one object of cinematography. Such a thing was very instructive for the

thorax and other parts of the body.

Hr. Kraus said that Groedel had done good service by his labours, but that the cardiac movements were rather indistinct.

At the Medical Society Hr. Wolff made a short communication on the importance of Non-tuberculous Dulness of the Apex of the Lung as shown in the case of a young man. The patient had atelectasis of the apex, with occasional bronchial breathing; that this was only transient was shown by the further course of the case, as well as by the negative result of subcutaneous injection of tuberculin, and of ophthalmic reaction. It was not an individual case, 7 per cent. of those who were in health resorts in whom an affection of the apex was present on their admission proved to be non-tuberculous. By the combination of clinical and biological methods of examination he hoped that our diagnosis would be still further improved.

Hr. Abel said that he had examined all cases of CARCINOMA

microscopically, and had found certain structures in carcinoma of various organs to which he believed he must now give publicity. They were stratified capsules with cellular contents arranged in heaps, which, after bursting of the capsule, could pass into the surrounding tissues. He considered these structures to be of a foreign nature, but he would not express any opinion as to their character or ætiological signifi-

cance.

Hr. Waldeyer said that he had "controlled" the preparations; he also believed them to be of a foreign nature, but could not give any explanation as to what they were. That they were exciters of carcinoma was more than questionable, they might just as well be saprophytes.

Hr. v. Hansemann had known the structures for a long time. They were products of the change that took place in the cells attacked. In carcinoma there were pluripolar cell divisions, so-called "Verklumpte" mitosa, which passed out of the cells. These apparent capsules, which the speaker had called "division spaces," were an apparent granulated fringe of protoplasm, whilst the internal protoplasm was homo-

Hr. C. Benda did not look on the structures as foreign, and had found exactly similar ones in normal genital glands of amphibia. He agreed in the opinion of the last speaker.

Hr. Waldeyer acknowledged the value of the objections that had been raised, and

Hr. Abel stuck to his own views.

AUSTRIA. Vienna, March 21't, 1909.

SIXTEENTH INTERNATIONAL CONGRESS.
THE committee have now fixed the date of meeting this year in Budapest, commencing on the 29th of August and ending on the 4th of September. The members fee is 25 kronen, and the Secretary's address is Budapest, VIII. Esterhazygasse 7, with whom all papers have to be lodged on or before the 30th of

COXA VARA. At the Gesellschaft Lorenz presented a patient he had treated by the bloodless method for coxa vara in a very bad form. This patient was now free from defect, either functionally or anatomically. Hitherto, he said, this disease was treated surgically by opening the part which exposed the patient to danger with frequently very unsatisfactory results. The methods followed might be roughly divided into two forms:—First, resection of the dislocated head, neck, and all down to the great trochanter or the simpler operation of removing the acetabulum; second, the orthopædic method which consisted in correcting the direction of the femur, either by intra-articular or pararticular interference, or the wedge form osteotomy. As a rule all intra-articular operations were unsatisfactory as life was endangered, 7 per cent. dying, or later contractions invariably resulting. The extra articular was not so dangerous, but could only be recognised as a palliative or compensatory correction for the deformity. The blood-

less treatment owes its origin to the fact that recent fractures heal quicker and better than old fractures. It is therefore necessary to produce the same condition by "re-infraction" reposition, and subsequent by "re-infraction" reposition, and subsequent retention of the fragments in the proper place. With the assistance of radiography this replacement is now easy, and the danger reduced to a minimum while the useful function of the limb is obtained.

Frisch thought this interesting method of treating coxa vara could only be very limited in its applica-tion as it would depend largely on the site of the deformity. Very few of these occur about the proximal end of the neck of the femur where this method would be the most serviceable; if occurring in the upper third of the femur, or if the curve had a wider extent he could not see where any advantage could be obtained by this method.

Ewald was of opinion that this bloodless method

could only be applied in the case of children, as adults would be too resisting, while the adductors and extensors would be apt to undo all that had been done. He thought Lorenz might have given them a more complete explanation of the technique of his method

when they could have better judged of its uses.

Lorenz said his method of treatment was the same in principle he fully described 18 years ago for angular fractures in the upper third of the femur, where the distal fragment must be brought into apposition to the proximal.

TUMOURS IN THE HYPOPHYSIS.

Eiselsberg, who is making a special study of this part of the body, showed two of his latest cases where he had operated with perfect success. The first of the two was a young girl, et. 16, who suffered from the "infantile habitus," fatty degeneration, hemiopia, and great reduction of vision. The subjective symptoms were principally represented by intolerable pains in the head. The Rontgen rays revealed a distinct enlargement of the hypophysis.

The operation revealed a large cyst of a chocolate brown colour, containing the same coloured fluid. The wound was closed and healed by first intention, but after eight days ominous symptoms appeared, necessitating a re-opening, when, behind the frontal sinus, the dura was found to be inflamed with dangerous symptoms of meningitis, which dispelled all hope of symptoms of meningitis, which disperses an arrection recovery. Two days later lumbar puncture was perwas examined at the institute, and large pus cells with bacteria were found to be present, which led to the belief in a streptococci infection. Subcutaneous in-jections of Paltauf's streptococcus serum, with intravenous injections of electrargol, were administered. During this treatment cultures of the spinal fluid had been made, with the result that no streptococci were present. The bacillus found belonged to the type of microbes known as bacillus fæcalis alcaligenes. This explained why the spinal liquor cleared up in a few days after, when another puncture was made. Gradually the patient recovered from the meningitis, and now, two months after the operation, is perfectly well. The headache has quite disappeared, the vision is improved, and since leaving hospital her mother tells me the girl has menstruated once.

The second case was that of a male, æt. 36, who was void of libido sexualis, suffered from bi-temporal hemianopsia, atrophy of both optic nerves, and severe pain in the head. The patient had been sent from Fuchs' Clinic for observation and operation. The operation revealed a large neoplasm, and, when examined, was found to be a malignant epithelioma, The post-operative temperature was favourable, and the wound healed by first intenton. The somnolent condition of the patient necessitated a longer time than usual in bed, as fears were entertained that an abscess was forming in the brain. Happily these fears are now dispelled, as the patient feels fresher and stronger than ever he was, and has also a normal appearance. The pain in the head has quite disappeared, and the

vision is greatly improved. The most important point to observe in the operation of the hypophysis is to keep strictly to the nasal line to avoid both optic nerves, as any deviation from the middle line may do irreparable damage.

### FROM OUR SPECIAL CORRESPONDENTS AT HOME.

#### EDINBURGH.

JUBILEE OF THE ROYAL HOSPITAL FOR SICK CHIDREN, EDINBURGH.

THE annual meeting of contributors to the hospital, held on March 17th, was of more than usual interest, because it marked the completion of the first half-century of the hospital's existence. Mr. James Clark, Chairman of the Directors, after alluding to the past year's work, said that the history of the institution during these 50 years had been one of unchecked progress. In 1859 a gentleman, Dr. John Smith, who was with them at the meeting to-day, started the movement by writing a letter to the *Scotsman*, over the signature of "Sigma," and that letter was the seed corn from which the institution arose. The suggestion was well received, and was clinched by another letter, signed "Merchant," which had a strong effect in bringing together and encouraging those who had resolved to found a children's hospital. The writer of that letter found a children's hospital. The writer of that letter, Mr. George Barclay, was also present that day. In the beginning £2,000 was gathered, and a house was purchased in Lauriston Lane, whence the hospital was transferred to Meadowside House, and subsequently to the present building, which cost £52,000, and was opened in 1895. Meanwhile, they had also accumulated funds amounting to nearly £50,000. This being their Jubilee, the directors thought it was a fitting occasion to make a step in advance by nominating two ladies as members of the Board of Management-Mrs. Wauchope and Mrs. Maconochie. In moving the customary resolution commending the hospital to the liberality of the public. Lord Salvesen pointed to two practical considerations: the first was that the Institution necessarily prevented a great waste of life; the second, that it set free for labour a great part of the community which, but for its existence, would have to devote themselves to the care of sick children. Lord Salvesen also spoke of the educational value of the hospital, and argued that the whole community benefited, indirectly at least, from the special skill which the physicians to the hospital acquired. Dr. Allan Jamieson, President of the Royal College of Physicians, seconded the resolution, and dwelt on the origin of hospitals in the Holy City of Jerusalem through the action of the Order of St. John. A phase of hospitalism not sufficiently insisted on, but which had great claims on the Christian public, was the educative moral effect exercised on the patients.

The speeches of Dr. John Smith and Mr. George Barclay, the venerable founders of the hospital, were listened to by the audience with close attention. Smith said that even in its embryonic stage the hospital got more substantial assistance than names to back it, for immediately after the letter signed "Sigma," Mr. George Barclay came forward with a gift of £100. It seemed at the time unaccountable that while so many hospitals for children existed throughout Europe, Edinburgh, so well known as a medical centre for any wears should have no institumedical centre for 300 years, should have no institu-tion of the kind. No doubt the matter had been discussed in professional circles, but public interest was never enlisted. Institutions of this kind were not merely benevolent; they were educational. Even in his student days he had perceived the importance of student days he had perceived the importance of studying in a hospital specially adapted for children, and this idea was confirmed by the insight gained when, in the stormy days of 1846—49, he, with his friend, Sir Henry Littlejohn, attended the Hôpital des Enfants Malades in Paris. He had only to add that in starting the scheme he had the assistance of his led fallow that of the leading members of the proin starting the scheme he had the assistance of his old fellow student, of the leading members of the profession, of the powerful Scotsman newspaper and its proprietor, Mr. J. R. Findlay, and of their late devoted Secretary, Mr. John Henry.

Mr. George Barclay concluded a short speech by saying that at the close of an exceptionally long life

it was a pleasure to look back on one good work at least in which he had helped. The older men might well be satisfied to hand on the burden of management to the younger and more active of to-day, who would carry on the good work in which they were all so

deeply interested, and which he was sure also was a blessing to the community.

### BELFAST

QUEEN'S UNIVERSITY, BELFAST.—ANNUAL STUDENTS' DINNER.—The annual dinner organised by the students at Queen's College was held on St. Patrick's Day, and was an occasion of special interest, as it was the first dinner of the new University. The Chancellor, the Right Hon. the Earl of Shaftesbury, presided, and over 100 were present, including many ladies. The speakers included the Chancellor, the Vice-Chancellor (President Hamilton), Sir Wm. Whitla, Professor Lindsay, Professor Symmers, Captain Cunningham, F.R.C.S.I., and others. The various speakers dwelt specially upon the happy ausnices for the future success of the Histories which are observed on all cess of the University, which are observed on all hands, and on the splendid opening for good work which lies before those connected with it. The undenominational and free character of the University was emphasised by more than one speaker.

THE MEDICAL CURRICULUM OF THE NEW UNIVERSITY. Great interest attaches to the rumours which are current in Belfast medical circles regarding the probable character of the medical curriculum in the Oueen's University of Belfast. It is said that the course will be a five years' one, without any pre-liminary Arts year. Examinations will be held in March and July, at the end of each session, and an examination will be held at the close of each medical year. The first will embrace the usual preliminary scientific subjects. The second year will be chiefly anatomy and physiology, which will then be finished with. The third examination will be on pathology, sanitary science, medical jurisprudence, and such subjects. The fourth will be on medicine, surgery, obstetrics, and ophthalmology, and with that examination attendance on lectures will finish; and the fifth year will be devoted to clinical work, ending with a clinical examination. Degrees will be granted on the combined results of the fourth and fifth examinations, which may be taken togther as a single final examina-tion if the student so prefers. In the clinical examination the various clinical teachers would take part, probably in some sort of rotation. If this sketch of the proposed curriculum is correct, the working of these sweeping changes will be watched with deep interest, for they promise to do away with some of the present difficulties.

### GLASGOW.

ANNUAL DINNER OF THE GLASGOW EASTERN MEDICAL SOCIETY.—This annual event was held on March 17th, Dr. Mathie, the President, in the chair. The guest of the evening was Sir Hector C. Cameron. Dr. Mathie paid a fitting tribute to Sir Hector as a distinguished clinical teacher and surgeon, and one who had gained the love and affection of his students. Sir Hector, in reply, said he could desire no better reputation than to feel he had secured the esteem of the numerous students that had passed through his hands. He re-called surgical work in the Glasgow Royal Infirmary forty years ago, and the horrible mortality that fol-lowed surgical operations from septicæmia and pyæmia, and how Lister's work had robbed surgery of its great evils and danger. Before Lister, it appeared, surgery was in a state of darkness. Sir Hector remarked that, without any change in the fabric of the Royal Infirmary, by the adoption of the teaching and practice of Lister, surgical results were obtained as good as any in even recently built hos-

St. Mungo's College.-Mr. J. T. Tullis, President of St. Mungo's College, addressed the students at the closing meeting of the winter session. He referred to the loss the College was sustaining by the appointment of Dr. Galt as Pathologist to the Sussex County Hospital. He stated that St. Mungo's College would not disappear, and that the negotiations with the University for the establishing of four clinical professors in connection with the new Royal Infirmary

were going on satisfactorily.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION.—A meeting of the Scottish Division of the Medico-Psychological Association was held in the Physiological Laboratory of Glasgow University on March 19th, 1909. Dr. Oswald, the Medical Superintendent of Gartnavel Asylum, was in the chair. Among those present were Dr. Thomas Clouston (of Edinburgh), Dr. Yellowlees (of Glasgow), and Dr. Ireland, all "grand old men" in mental diseases. Dr. Mackenzie, of the Pathological Department of the University. delivered a very interesting lecture on "General Paralysis and Syphilis." He traced a close analogy between syphilis syphins." He traced a close analogy between syphins and trypano-somiasis as far as their general life history was concerned, and the effects on the brain both diseases produced. Dr. Mackenzie demonstrated the hæmolytic test as applied to germ disease, and its use in general paralysis as a diagnostic test. He stated that when iodide of potassium was administered to a patient, it could not be found in the cerebro-spinal fluid, and suggested that possibly the injections of suitable drugs or serum into the spinal canal might alleviate or possibly cure cases of general paralysis. He also emphasised the fact that microbes get used to small doses of drugs, and may not be killed by substantial doses given later on, and thus on the need of the dose of a particular remedy being given early in effective quantities. Dr. Henry Watt gave a short account of recent progress in the analysis of reactions, and demonstrated the apparatus used in this branch of knowledge, which promises to be of inestimable value in detecting early signs of brain disease.

### LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

NATIONAL SERVICE AND THE MEDICAL PROFESSION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.
SIR,—During the past twelve months several meetings of branches of the National Service League have been recorded in the daily papers, and it is to be noticed that medical men have been prominent in organising and addressing such meetings. Of course, medical men do not lay themselves open to criticism for taking part, as any citizen may do, in any legitimate political movement. It is different, however, when they pose as representing the views of the profession, as would seem to be inferred from the appearance of gentlemen occupying official positions in the profession at certain meetings lately. With such happenings, the public is likely to accept the view that the profession is all of one mind as regards compulsory service, a view far removed from the truth.

With the political aspect of the movement we have no concern, but it is more than open to question whether universal military service is of benefit to the physique of a nation. It is possible that regular drill and military discipline may improve the physical con-dition to some extent, but far outweighing any such benefits is the increase of venereal disease which we must expect if the youth of our country are condemned to barrack life for two or three years of their lives. In Germany it is well recognised that military service increases the amount of the venereal diseases, which indeed, as far as their history goes, have always been peculiarly the diseases of armies. The garrison towns of Germany are known to be the hotbeds of the most virulent forms of venereal disease, and the revelations of the life in such places made in a popular novel a year or two ago are still fresh in the public mind. This side of the question is not likely to be discussed at the tea-parties where the National Service propaganda is principally carried on, but it would be well for medical men at least to give it due consideration before preachers on behalf of the movement. appearing as f the movement.
I am, Sir, yours, etc.,
CRITICUS.

MIDWIVES V. MEDICAL MEN To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—I am very pleased to note that you "do not hold yourself responsible for the opinions expressed by

your correspondents." It was with astonishment that I read in your last week's issue that Dr. Griffith maintains that a well-trained midwife should be able to administer chloroform. This is aiding and abetting the formation of an inferior order of medical practitioner with a vengeance! I hope fervently that it

will not come to pass in my lifetime.

I read in this week's *Medical Journal* of a rural nurse being driven from village to village in a smart dogcart and attending a medical man's patients with-out his knowledge and directions, etc. Now, we are in a great measure to blame for this state of affairs. We think that if we oppose the wishes of ladies serving on committees that they will by their glib tongues do us damage. Let them! Magna est veritas, et prævalebit. Let us consider the welfare of our profession and not look at medical questions from a selfish and individualistic point of view. Let us, furthermore, hold the whiphand of these lay committees, and if we see anything done which lowers the dignity of our profession and falsely exalts the position of the unqualified person, let us not hesitate to speak out, and ever keep before the eyes of the public that there is all the difference between a nurse and a duly qualified man.

I am, Sir, yours truly, S. J. Ross.

Monkhams, Bedford. March 21st, 1909.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR.—You say in your article on "Medical SIR,—You say in your article on "Medical Charity," "that salvation must come from within." From that standpoint would it help our badly remunerated profession were they to agitate for all the improvements in the education of midwives which Dr. Griffith advocates in his letter to you last week? Would it not tend to the further commercial ruin of Would it not tend to the further commercial ruin of the medical profession if what at present is an inferior order of competing medical practitioners were by the aid of doctors educated and elevated to an equality with them, and "become capable of administering chloroform, dosing with hypodermic medicaments and using specula," etc.? At present young practitioners find midwives sufficiently competitive, but if educated so that "they will not always have to be sending for the doctor," they will be much more formidable opponents. Is the speculum to be used to note the dilatation of the os, or is she to repair laceration of opponents. Is the spectrum to be used to note the dilatation of the os, or is she to repair laceration of it after completion of labour? The more ignorant the midwife remains the better for doctors. Why should we try to curtail a source of income by handing another branch of medicine over to a separate body of practitioners? Enough has been done in that direction already.

I am, Sir, yours truly, JAMES HAMILTON.

Chelsea, March 20th, 1909.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—Dr. G. de G. Griffith is quite right in his atement, The land is flooded with Midwives." statement, May I inquire what sort of berths can be found for all? Why not spell berths with an I? The profession is already poached upon from all sides, and now in order to prevent the doctor being called in, the midwife is to take a step higher than she has had and "administer hypodermics," "give chloroform," vaccinate and probably circumcise. "A little learning is a dangerous thing," and the midwife should have her exact work taught her, and be punishable should she exceed her rules, unless in cases of dire necessity. Soon nothing will be left to the medical man to practice except patience.

i am, Sir, yours truly,

ALEXANDER DUKE.

Lendon, W.

### SMALL-POX AT BRISTOL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—I am sorry to say your account of small-pox in Bristol is in many respects inaccurate and simisleading.

In the first place the disease has not become uncomfortably disseminated in the city; there have been two well circumscribed groups of cases, as detailed in the printed letter

In the second place I have not lost control of the disease in the city, and I do not fear an outbreak of some severity. The disease appears to be absolutely

under control in the city.

In the third place the Local Government Board did not send down their Medical Inspector (Dr. Sweeting) because of the prevalence of disease in the city, but because a co-existent infection of certain adjacent districts in the county rendered it necessary to secure co-operation between the neighbouring authorities and Bristol in the matter of vaccination, contact supervision, etc.

It is not internal spread that we fear, but possible

cross-infection from one district to another.

With these slight alterations, your description may

I am, Sir, yours truly, D. S. DAVIES, M.D., M.O.H.

March 18th, 1909.

[COPY.]

CITY OF BRISTOL. PORT OF BRISTOL. DEAR SIR,—The position as to Small-pox in Bristol is this:

An introduction took place in December, which led to 15 cases of small-pox, the last case being notified on March 1st.

From the country district outside Bristol another introduction took place into a Public Institution on February 16th, this case infected 7 persons in the city-all removed to hospital and doing well.

During the present week only one notification of small-pox has been received. So far as the City and Port of Bristol are concerned there is at present no epidemic in the City or Port, but the special precautions as to vaccination and re-vaccination advised by the Local Government Board, and being actively adopted, are in order to anticipate any extension in the country districts and re-introductions into the city, and to prevent extension from the cases already introduced into Bristol.

It is fully believed that these precautions, which are being taken in advance of any actual epidemic, will prevent the establishment of small-pox in the city, and the fact that reasonable precautions against invasion of disease are being taken in time instead or waiting for a wide extension of the disease is a reason for confidence in the Health Authority of the

city.

Yours faithfully, D. S. DAVIES, M.D., Medical Officer of Health.

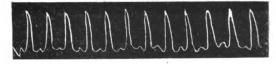

OXYGEN IN SPORT.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—If not putting to too great a trial the patience of your readers, I will ask you to allow me to make a last reply to Dr. Leonard Hill, who continues to entirely misunderstand the gist as well as the text of my first letter.

Dr. Leonard Hill says: - "The inhalation of oxygen after forced exercise has no effect on the breathing volume or the breathing frequency. . The sphygmograph is not an instrument by which blood pressure can be measured; it is difficult to apply it twice without modifying the form of the tracings obtained. I, by this means, have hitherto been unable to obtain trustworthy evidence as to the effect of oxygen.

I have not written a word that could warrant the conclusion that I supposed that oxygen increased the adequacy of the lung when given after forced exercise. What I did state was that it did so when administered during exercise—that an effort can be made, thanks to oxygen so inhaled, which helps the blood through the lungs and so enables a sprint to be continued when an athlete would otherwise have been pumped out by lung failure. If this is not increasing the adequacy of the lung, I don't know what is.

Dr. Leonard Hill says, moreover, that he has not been able to show this ("obtain trustworthy evidence") by the sphygmograph; but that I have done so is shown by the tracings I published, which are to be found

in the accompanying pamphlet, and the blocks of which I send, in case you may think fit to use them.

This is the whole point: I have never claimed to have discovered the obvious. I remarked in my first letter that there was nothing new under the sun, and that oxygen had no doubt been administered by others in sport before me.

I have only claimed to have shown by "trustworthy evidence" the mechanism of the physiological experievidence" the mechanism of the physiological experiment Dr. Leonard Hill has failed to realise.

A comparison of the two tracings, the first taken from a sprinter during forced exercise and entirely pumped out—i.e., with a systemic accumulation of CO<sub>2</sub> beyond the adequacy of the lung—the second during the inhalation of oxygen, shows the restoration of tension I allude to, which can only have been

obtained by enabling the subject to go on breathing and so to deal more efficaciously with the excess of carbonic acid. This, I think, may be called increasing the adequacy of the lung.

With regard to the accuracy of sphygmographic tracings, this depends, no doubt, upon the experimenter. For my own part, I have taken thousands of them during the last thirty years, and in the same conditions I can always obtain sensibly the same tracings.

I am, Sir, yours truly, OSCAR JENNINGS, M.D.

Paris, March 22nd, 1909.

THE MEDICAL DEFENCE UNION AND INSURANCE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.
SIR,—In consequence of the demand which has lately sprung up for insurance of medical practitioners against the risk of pecuniary loss when adverse verdicts, involving payment of plaintiff's costs and "damages," are returned against them in civil actions in their professional work, the Council of the Medical Defence Union has concluded arrangements with a company of the very highest repute, "the Yorkshire Insurance Company," for such indemnity. All members of the Medical Defence Union can now, by payment of a yearly premium of the smal lsum of 7s. 6d., effect insurance up to the limit of £2,000—and for a payment of 9s, up to the limit of £2,000—in any case defended by the Union in this respect. For fuller particulars and general conditions members are reterred to the Secretary of the Yorkshire Insurance Company (founded 1824), Bank Buildings, Princes Street, London, E.C., to whom all applications by members of the Union for policies should be made.

I am, Sir, yours truly,

A. G. BATEMAN, General Secretary.

Medical Defence Union.

INCORPORATED DENTAL HOSPITAL OF

IRELAND.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,-I am desired by the staff of the Incorporated Dental Hospital of Ireland to send you the subjoined resolutions adopted unanimously at a meeting of that body held in Dublin on the 8th inst.

I may inform you that the hospital staff comprises 25 dentists (8 of whom hold additional medical qualification), and 11 medical men, anæsthetists.

I am, Sir, yours truly, GEO. M. P. MURRAY, Hon. Sec.

March 15th, 1909. [The resolutions will be found on p. 308 of our present issue.—ED. M. P. AND C.]

### OBITUARY.

CAPTAIN FREDERICK HALLAM HARDY, R.A.M.C., M.R.C.S., L.R.C.P. CAPTAIN FREDERICK HALLAM HARDY, R.A.M.C.,

who died at Aden on March 8th of sleeping sickness, on the voyage home from Nyasaland, was the son of Major-General F. Hardy, C.B., of Shawford, Winchester. Captain Hardy went out to British Central Africa as a civil surgeon under the Foreign Office in 1898. He served in the Southern Angoniland expedition 1898, and received the medal with clasp. In British Central Africa, in 1899, he took part in the expedition against Nkamba, and received the medal with clasp. He was gazetted to the Royal Army Medical Corps in June, 1900. He received his commission in the King's African Rifles in 1901. In that year he took part in the expedition up the Gambia, and was mentioned in despatches and received the clasp. He was in East Africa in 1902-4 during the operations in Somaliland, and saw action at Jidballi, for which he received two clasps. In the autumn of 1906 Captain Hardy was seconded for service in British Central Africa under the Colonial Office, and was carrying out scientific research into the causes of

tropical diseases.

While treating the only case of sleeping sickness known in the country he contracted the disease, and the news of his serious illness was telegraphed home to his relatives early in January. He was placed in charge of Dr. Kinghorne, of the Liverpool School of Tropical Diseases, who was accompanying him to England.

### SPECIAL ARTICLES.

### INCORPORATED DENTAL HOSPITAL OF IRELAND. AT a meeting held on March 12th, 1909; the fol-

lowing resolutions were adopted:

I.—That the members of the staff of the Ircorporated Dental Hospital of Ireland, having had under consideration the General Anæsthetics Bill, 1908, as submitted by the Privy Council to the General Medical Council, do approve the general principles of the Bill, but are of opinion that the clauses relating to registered dentists should be modified.

tered dentists should be modified.

They would respectfully point out that dental students, before they present themselves for their final examination, are required to produce evidence of having received instruction in general medicine, surgery and physiology, as well as in the administration of anæsthetics; they are, consequently, of opinion that if the course of instruction in the latter subject were made identical for medical and dental students, the same privileges could with perfect propriety be extended to dentists as are given to medical men by Clause 1 of the Bill.

In order to give effect to these proposals they would suggest the following amendments to the Bill. That Clause I should read as follows:

That clause I should read as 1010ws:—
That any person other than a legally qualified medical practitioner registered under the Medical Acts, or legally qualified dental practitioner registered under the Dentists Act, 1878, who shall wilfully administer, or cause to be administered, to any other than the inhelation or otherwise any drug or subperson by inhalation or otherwise, any drug or substance whether solid, liquid, vaporous, or gaseous, and whether pure or mixed with any other drug or substance, with the object of producing a state of unconsciousness during any medical, or surgical, or

dental operation act or procedure, or during child-birth, shall be liable on conviction before a court of summary jurisdiction for such offence to a penalty not exceeding ten pounds, and in the case of a second or subsequent conviction to a penalty not exceeding twenty pounds, provided always that a person shall not be liable to a penalty under this section if in conducting such administration he was acting under the immediate direction and supervision of a legally qualified medical or dental practitioner, or if the cir-cumstances attending the administration were such that he had reasonable grounds for believing, and did believe, that the delay which would have arisen in obtaining a legally qualified medical or dental practitioner would have endangered life.
(2) That Clause 2 be amended as follows:—

All licensing bodies in the United Kingdom recognised by the General Council of Medical Education and Registration of the United Kingdom shall require that all candidates, both medical and dental, before presenting themselves for their final examinations, shall have received thorough theoretical and practical instruction in anæsthetics, and shall have personally administered anæsthetics, under the supervision and to the complete satisfaction of their respective teachers.

(3) That Clause 3 be deleted. Second resolution :-

II.—That no legislation which does not deal with local anæsthetics will adequately meet the mischief against which the General Anæsthetics Bill is aimed.

### REVIEWS OF BOOKS.

A SYSTEM OF MEDICINE. (a)

WE have received for review the two volumes which. in the present edition of Professor Allbutt's wellwork, take the place of the fourth volume in the original edition. Part I. of Volume IV. deals with diseases of the liver, pancreas, ductless glands, and kidney. It has undergone very considerable changes, whilst the original sections on diseases of the nose, pharynx, and larynx have been removed. An entirely new series of articles, including one on diseases of the

ear, form Part II. of Volume IV.

Part I. consists of four sections. The first of these deals with the diseases of the liver, and occupies some 200 pages. The principal contributors are Drs. A. Keith, William Hunter, John Thomson, Herringham, and Hale White. The section ends with two lucidly written articles by Mr. Mayo Robson on diseases of the gall-bladder and bile-ducts, and on gall-stones. The second section deals with diseases of the pancreas, and has been contributed by Drs. Bosanquet and Pitt. The third section deals with diseases of the ductless glands and some other conditions, such as infantilism, obesity, adiposis dolorosa, and ædema. The principal contributors are Drs. Hector Mackenzie, H. D. Rolleston, George Murray, John Thomson, and Sir Dyce Duckworth. The fourth section deals with diseases of the kidney and has been written by Professional eases of the kidney, and has been written by Professor Rose Bradford, Professor Macalister, and Mr. Henry

The volume is a most valuable and interesting one. Every article bears the stamp of authority, and is obviously written by one who is an authority on his subject. It is, we think, a pity, however, that either the Editor, or the contributors, did not make an effort to have the work as a whole properly illustrated. In the present volume there are 760 pages and nine illus-trations. Of these, four are simple diagrams, and the remainder are reproduced photographs. It is, of course, a fact that several of the subjects discussed do not require illustration, but in other subjects the reverse is the case, and the value of the articles dealing with them would have been materially increased by the addition of suitable illustrations.

The second part of Volume IV. deals with subjects

<sup>(</sup>a) "A System of Medicine by many Writers." Edited by Sir Clifford Allbutt, K.C.B., M.D., LL.D., F.R.C.P., Regius Professor of Physic in the University of Cambridge, and Humphry Davy Rolleston., M.D., F.R.C.P., Senior Physician to St. George's Hospital, &c., &c. Vol. IV. Part I, pp. xii and 784, and Part II, pp. xxvi and 586 London: Macmillan and Co. 1908.

which are not as a rule discussed in treatises on medicine. The editors recognise this, and explain in the preface the reason for the inclusion in the series of "so special and even surgical" a subject as diseases of the ear. The editors do not apply this explanation to the remainder of the volume, but as it deals with diseases of the nose, pharynx, and larynx, and as these regions have become almost entirely the domain of a surgical specialist, the explanation might equally well apply to it. However, that does not affect the merit of the volume, which, as a modern monograph on diseases of the nose, throat, and ear, seems to be

wholly admirable. This part is divided into four sections. The first deals with diseases of the nose, and has been written by, amongst others, Dr. Greville MacDonald, Mr. Herbert Tilley, Sir Felix Semon, and Dr. F. de H. Hall. The second section deals with diseases of the pharynx, and has been written by Sir Felix Semon and Dr. P. W. Williams. The third section deals with diseases of the larynx, and has been written by the same authors. It is followed by four separate articles on direct laryngoscopy, foreign bodies in the air passages, diseases of the trachea, and the throat and naso-pharynx in acute specific fevers. The fourth section deals with diseases of the ear, and is written by, amongst others, Drs. Barr, Porter, Tod, Grant, Milligan, Ballance, McBride, and Love. There are some fourteen plates, almost all of which are good and well reproduced. There are, in addition, some sixty illustrations in the text. We should be glad to say that these also are good, but with a very few excepthat these also are good, but with a very lew excep-tions they are extremely poor. We notice some that seem to have been specially drawn for the work by Mr. Sewell, and so far as the artist's part is concerned they are good. They have, however, been spoiled by careless reproduction. When will English publishers learn that half-tone blocks for use in works such as this cannot be prepared in a similar manner to that adopted in the case of an evening paper? A good drawing is worthy of a good block, and will well repay the trifling extra expense involved. Apart from the illustrations, we have nothing but praise for the fourth volume of this very valuable system of medicine.

#### THE MUSCLES OF THE EYE. (a)

This monumental monograph on the ocular muscles is, with this second volume, completed. It is a work of which the author may well be proud, even on the grounds of the evidence of industry alone. Moreover, it is a revelation, surprising in its extent, of the mag nitude of the literature which already exists upon this special subject. We drew attention to the large number of pages devoted to the Bibliography in the first volume; but in the volume before us these pages reach almost three-score-and-ten in number, which shows very plainly, not only the labour which the compilation of the work must have involved, but also that the plea advanced by the author, in justification of his task, namely, "to collect actual facts relating to the ocular muscles, arrange them in order, and state them in terms as clear and simple as possible," was scund in its inception. Ophthalmic surgeons, generally, can only feel indebted to the author for this great undertaking-an undertaking so practically conceived and successfully carried out. As showing the scope of this volume, it may be pointed out that the subject is dealt with in five parts. (1) Ocular muscle imbalance; (2) Deviations due to lesions in the extra-ocular lance; (2) Deviations due to lesions in the extra-ocular muscles or in the globe (Strabismus); (3) Deviations due to lesions in the brain or in the nerves (the paralyses); (4) Atypical movements—inflammations and injuries of the muscles; (5) Operations on the muscles. Each of these various parts is discussed exhaustively. It is interesting, among other things, to note that the author does not identify himself with that class of ophthalmic surgeons in America which is disposed to attribute so many of the ills to which flesh is heir to imperfection of the eyes. Referring to "exaggerated opinions of eye-strain," he says, "One American writer has a series of so-called 'biographic clinics,' in which he has shown that most of the persons selected for consideration had rather misanthropic views, indigestion, or ill-tempers, and, therefore, concluded that these conditions were due to imperfections of ocular muscles. . . From similar data we would be forced to conclude that Ezekiel, with his lamentations, or Job, and other less interesting gentlemen who were inclined to introspection, also were afflicted with eyestrain and suffered simply for lack of a competent refractionist. Such literary diversions are clever and popular, of course, but let us not call them even semi-scientific, or attempt to treat them seriously."

The chapter upon the operative treatment of muscle deviations deals with many interesting and important points. "Some operations," he says, "on the ocular muscles demand as much care and exactness for their proper execution as operations upon the iris and lens." Again: "Among the multitude of operations which have been proposed for advancement, it is difficult to single out any one which is pre-eminently the best." He defines the choice between an advancement operation and tenotomy as follows:—"Advancement is always indicated for a typical passive deviation, usually for a composite deviation, and it is possible to produce improvement with it in an actual deviation. Tenotomy, however, is much the simpler operation. It is especially indicated for all actual deviations, and the good results constantly obtained with it in this class of cases, and sometimes in cases of the composite type, cause tenotomy to hold its place in spite of theoretical objections." Possibly to this chapter ophthalmic surgeons will turn for reference more than to any other.

### A PHILOSOPHY OF NATURE. (a)

NOTHING has been more striking in the history of the philosophy of science as it concerns our generation than the return that has been made by scientific minds to concepts long regarded as illegitimate. A few years ago the physiologist thought he was only at liberty to make use of chemical and physical laws in the explanation of the phenomena in his department of science, and the biologist in his wider sphere guided himself by the same canons of thought. The concept himself by the same canons of thought. The concept of life, of the "life-force" of the older physiologists, was banished as something superstitious and quite alien to the scientific categories. But those days are past, and at the last meeting of the British Association the President of the Physiological Section forecast the bankruptcy of the old ideas and the necessity of again taking life and the phenomena of life into consideration. In this fresh conspectus, chemistry and physics are to be regarded as insufficient, and every concept in our armoury of ideas is to be given its chance.

It is in some such spirit as this that Mr. T. W. Rolleston has been thinking, and he has given us the result of this thought in a neat volume. Mr. Rolleston has long been known as a polished and scholarly writer on literary subjects, but we think that this is his first original essay in the direction of science or philosophy. He has shown that he has followed very closely the writings of modern biologists, and he has got a good grasp of their views. In philosophy he is, as we hope to show, an original thinker, while as regards his literary expression we are pleased to find that his change of subject-matter has not made Mr. Rolleston's hand forget its cunning.

In the earlier part of his essay Mr. Rolleston argues,

and, we think, argues convincingly, against the purely mechanical theory of the universe. The living being is essentially different from a machine. The term "living machine" is a contradiction, since what is peculiar about a living thing—its power of construct-

<sup>(</sup>a) "The Muscles of the Eye." By Lucien Horne, M.A., M.D. In two volumes. Vol. II, Pathology and Treatment. Illustrated, New York and London: G. P. Putnams Sons. 1908.

<sup>(</sup>a) "Parallel Paths: A Study in Biology, Ethics, and Art." By T. W. Rolleston. 8vo. Pp. xvi. and 300. London: Duckworth and Co.

ing itself, of adapting itself to its surroundings, is precisely what a machine cannot do.

Again, Mr. Rolleston attempts to assign to the Darwinian hypothesis its place in the scheme of the universe. He is by no means an anti-Darwinian, and he gives to the doctrine of natural selection all that can be claimed for it in the explanation of development. But the doctrine of natural selection only explains the how of evolution; it leaves the why still to seek. It is as if someone were to explain a railway system by pointing to the metals, and the sleepers, and the permanent way, but were to say nothing of the force of steam which makes the engine to travel. Natural selection is the path along which the X-force has made us to travel. What is this X?

This is the problem Mr. Rolleston sets before him, and he pursues it through the domains of biology, ethics, and art. We do not think he defines it anywhere in set terms, but he tells us (p. 155) that it "is a controlling and directing force, making, through countless varieties of being, for one clear and definable end—the realisation of life." We know no force but by its effects, and therefore this description is not as empty as one might think. "The realisation of life" is the end, the controlling force, which has guided us along the paths of evolution. Mr. Rolleston follows this out in ethics and art. "We have before us," he says (p. 234) "a clear conception of the criterion and the sanction of ethical action. The criterion is applied when we ask of anything done by man, 'Does it further life in the whole?' The sanction is found

whole." His judgment of art is by the same criterion. What Mr. Rolleston has made clear is the necessity for some other principle than purely mechanical ones in the explanation of the universe. The principle he chooses—Life—it may be objected, is somewhat void and vague. This is true, but it is necessarily so, and we can only hope to make it less void and vague by a careful study of the phenomena by which it manifests itself

in the fact that each of us is an organic part of that

The book should be read by everyone with a philosophical turn of mind who wishes to learn something of the fundamental principles which underlie modern science.

### CLINICAL DIAGNOSIS. (a)

In the preface to the first edition of this work is a paragraph which is worth quoting at length. Dr. Emerson writes: "The function of the clinical laboratory worker is to aid the ward worker. The findings of the former are seldom conclusive, and must be interpreted in the light of the ward findings. . The clinical chemist must be first a good clinician and second a chemist; he should remember that even from the laboratory point of view his stethoscope is of more importance than his microscope, his percussion finger than his whole outfit of chemical apparatus." It is not surprising that, with this conception of what a laboratory worker should be, the author has written a book on clinical diagnosis of which a second edition is required after only two years. Much of the book has been rewritten, and it has been considerably amplified, so that the subject is very fully dealt with. There are many excellent illustrations, which greatly enhance the value of the text, indeed, several coloured plates are the best we have seen of the subjects which they depict. work is divided into six chapters, the first deals with the examination of the sputum, and though comparatively short, gives an exhaustive description of the various kinds of sputa and the numerous objects to be found in them. This chapter is followed by the longest in the book on the examination of urine. In it the value of cystoscopy as a means of determining the kidney efficiency is keenly criticised, but no mention is made of Sir Almroth Wright's method by hæmolysis, which is not open to the same objections. It is not surprising, then, that under functional albuminuria, although the condition is described especially carefully, it is not stated that the kidney efficiency is normal, a truth which was arrived at by the hæmolytic method. Chapter 3 deals with the examination of the gastric contents. We think that undue importance has been given to the presence or absence of free hydrochloric acid, as opposed to the amount of active hydrochloric acid; and would welome the addition of Willcox's method of estimating the latter. If this were employed it would perhaps lead to a modification of the author's rather pessimistic attitude towards the likelihood of early diagnosis in cases of gastric carcinoma. Chapter 4 concerns diagnosis by examination of the fæces. Hæmatology follows in Chapter 5, which is replete with especially beautiful illustra-tions of blood films and of the malarial parasites. To English readers it appears strange that Leishman's stain is not mentioned specifically. A careful account of the opsonic method is given, but we think that the pipette illustrated, for the collection of blood from the finger, is unduly cumbersome, and possesses no advantages over that introduced by the originator of the method. Chapter 6 contains an account of the characters of the various other body fluids, normal and abnormal. It is short relatively to the rest of the book.

### DISEASES OF THE EYE. (a)

THE author's object in writing this book was to present to students and to practitioners a short, practical manual of diseases of the eye; and for this reason he avoids any theorising or discussion, but keeps himself to hard facts, and devotes more attention to the practical side of his work by dealing more fully with the diseases most frequently met with in general practice than with those of the deeper tunics of the eye.

The first 64 pages are given to methods of examination and elementary optics and refraction, and, as might be expected, the subjects have to be treated in a rather sketchy way when such a limited space is set apart for them. We must say, however, that the author has made the best of it. There is a bad "slip" on page 35, where it is stated that retinal images, to be appreciated as separate objects, must subtend an angle of 5°. The error is repeated on page 56. As the work is one meant for beginners, the reviewer may be permitted, in the interests of the subject, to further take exception to the letters on page 57 being called "Sneller's test types." Having got past these pages, the book comes out in its true light. The various diseases of the conjunctiva, cornea, sclerotic, etc., are dealt with in a very concise, practical way, the treatment being to the point, and alternatives omitted in The chapters on the conjunctiva, retina, and ocular muscles struck us as particularly good. On page 210 we are told that "opaque nerve fibres" are flail-like in shape. We fancy "flame" or "tail"-like would be happier similes, besides being more readily recognised. The illustrations are mostly original and very good, many being micro-photographs of pathological conditions such as diseases of the retina and optic nerve, and of glaucoma. We wish Mr. Mayou's book the success which it deserves, for it must appeal to a large number of students who are seeking an elementary multum in parvo at a modest price.

### MEDICAL NEWS IN BRIEF.

Semon Testimonial.

A GENERAL meeting of laryngologists was held at the Royal Society of Medicine on March 5th to organise a testimonial to Sir Felix Semon on the occasion of his retirement. This takes place at the end of the coming June.

Mr. Butlin was unanimously elected Chairman of

Mr. Butlin was unanimously elected Chairman of the General Committee, and Dr. Dundas Grant, President of the Laryngological Section, was elected Chairman of the Executive Committee, which consists

of the following:—Mr. Butlin (Chairman General Committee); Dr. Dundas Grant (Chairman of the Executive Committee); Mr. Charters Symonds; Mr. Cresswell Baber; Dr. J. B. Ball; Dr. Law; Dr. McBride; Mr. Herbert Tilley; Mr. E. Waggett; Dr. Sandford; Dr. de Havilland Hall; Dr. Scanes Spicer; Dr. St. Clair Thomson (Hon. Treasurer, 28 Queen Anne Street); Dr. Watson Williams (Hon. Secretary, 4 Clifton Park Bristol): Dr. H. J. Davis (Hon. Sec. 4 Clifton Park, Bristol); Dr. H. J. Davis (Hon. Secretary, 8 Portman Street, London, W.). Subscriptions may be forwarded to the Honorary Treasurer.

### Irish Medical Schools' and Graduates' Association.

ABOUT two hundred ladies and gentlemen sat down to the festival dinner of this Association, held at the Hotel Cecil on Thursday, March 18th. In the unavoidable absence of the Right Honourable Lord Ashavoidable absence of the Right Honourable Lord Ashbourne, the chair was occupied by Dr. François A. de Thierry Mouillot, who was supported by a large number of distinguished men, amongst whom may be mentioned Sir Robert Ball, Prof. Arthur Barker, of University College Hospital, Sir Alfred Keogh, K.C.B., Surgeon-General W. L. Gubbins, C.B., M.V.O., Surgeon-Colonel John J. de L. Marshall, Dr. L. S. McManus, Mr. Canny Ryall, Dr. P. S. Abraham, Mr. Chas. Ryall, Mr. W. Ernest Lane, Dr. Dawson Williams, Mr. John Murray, Dr. Voelcker, Mr. Willmott Evans, Mr. Stonham, C.M.G., Dr. Wm. Hill, Dr. Herschel, etc., etc.; also, Lieut. G. Abraham, R.L.M.I., and Lieut. John Smith McCombe, R.A.M.C. After the usual loyal toasts had been duly honoured, Dr. Jameson Macan, Chairman of the Council, intro-R.L.M.I., and Lieut. John Smith McCombe, R.A.M.C. After the usual loyal toasts had been duly honoured, Dr. Jameson Macan, Chairman of the Council, introduced Lieut. John Smith McCombe, R.A.M.C., to whom the Chairman presented the Arnott Memorial Medal as a recognition of Mr. McCombe's bravery in attempting to save the life of a youth who fell into the river off Millbank. Although Mr. McCombe's efforts to save the boy were unsuccessful, owing to the muddy condition of the water preventing his repeated dives from carrying out his intention, he continued his search until he himself was so exhausted that he had to be assisted ashore. The toast of "Our Defenders" was ably proposed by Dr. James Macdonald and responded to by Lieut. G. J. Abraham, R.M.L.I., Sir Alfred Keogh, and Colonel J. de L. Marshall, the latter showing that officers of the Territorials could at least hold more than their own in after-dinner oratory. Dr. L. S. McManus then, in a witty speech gave "Our Guests," the toast being responded to by Surgeon-General Gubbins. The best discourse of the evening was then pronounced by Sir Robert Ball, F.R.S., in proposing "The Association." ite gave some very amusing reminiscences of Sir P. Crampton and of Dr. Haughton. "The President" was proposed by Dr. Edgcome, and with Dr. Mouillot's answer a very enjoyable evening was brought to a close, although we do not think the musical and variety entertainment was up to the usual mark of the dinners of the Association; in fact, with musical and variety entertainment was up to the usual mark of the dinners of the Association; in fact, with regard to the variety portions (thought reading, etc.), it seemed to us that the only people who could appreciate the performance were those in the immediate vicinity of the performer.

#### ion Ophthalmic Hospital Guild.

THE annual meeting of this guild, which is composed of ladies engaged in working for the support of the Royal London Ophthalmic Hospital, was held on March 16th at the hospital, Mrs. Adler presiding. The report, which was read by Mrs. Marcus Gunn, stated that the amount collected in 1908 showed an increase of £53 over that in 1907. The collection towards the cot fund was also satisfactory. The sum of £100 had again been contributed by the guild for the upkeep of a cot and bed, and £157 had been expended by the works committee. There were now 270 members of the guild, Mrs. Adler, in moving the adoption of the report, emphasised the urgent need of additional financial support. Only a few days ago she saw lying in the children's ward a baby who was born blind, but, owing to the skill of the physicians and surgeons, there was every probability of its receiving sight, while hundreds of others with imperfect vision were saved from becoming totally blind. Patients came to

the hospital from all parts of the country. Miss A. S. Lawrence, in seconding the motion, said that 6,000 children attending the London elementary schools had defective eyesight and required to attend the eye hospitals as out-patients, yet the total accommodation of all the I ondon eye hospitals was equal to dealing with only 10,000 a year. The report was adopted.

#### Disinfection of Anthrax.

Dr. J. S. Holden, medical officer of health for Melford, has frequently reported on the occurrence of anthrax among employees in a local workshop where foreign and raw horsebair is largely handled. Just before the new Anthrax Order was issued by Home Office last year, three cases of anthrax suddenly occurred in this workshop. He suggested that each bale of horsehair, just as received, should first be thoroughly soaked in a hot antiseptic dilution, and then opened and sorted while still damp, so that no dust could possibly fly about. The owners of the workshop and the Inspector of Factories approved this suggestion and advised that it might be substituted for the new Anthrax Order. Application was made to the Home Office and the certificate granted. The process adopted is, that each bale of horsehair is immersed in a tank containing I per cent. or more of Cyllin in hot solution. In this position the bale is ripped open, so that the hair gets well soaked; after 1½ hours' immersion the hair is drained and then sorted. Dr. Holden reports that since this process was commenced early in April, no case of anthrax has occurred, and all dust is effectually prevented.

#### Spotted Fever near Klimallock .

THE family of a labourer, residing at Bantard, Co. Cork, has been attacked by cerebro-spinal fever, from the effects of which two members of it have died, and a third is seriously ill. A few days since a child, æt. 4 years, got unwell, and died on Wednesday or Thursday; a boy, æt. 6 years, also got indisposed, and died yesterday (Friday), while the sister, æt. 7, has been removed to Kilmallock Union Hospital, where she lies in a precarious condition. The disease is pronounced to be cerebrc-spinal fever.

#### Vital Statistics.

THE deaths registered last week in the eighty great towns of the United Kingdom corresponded to an annual rate of 22.1 per 1,000 of their aggregate population. In the preceding three weeks the rates had been 18.1, 19.1, and 21.3.

Measured by last week's mortality, the highest

Measured by last week's mortality, the highest annual death-rates per 1,000 living were:—From all causes, 27.0 in Stockport, 26.2 in Liverpol, in Bootle and Salford, 35.1 in St. Helens, and 27.5 in Dublin, 27.0 in Birmingham, 29.0 in Bury, and 34.6 in Brighton. The death-rate from measles was 4.7 in Sheffield, 4.0 in Birmingham, 5.9 in West Hartlepool, 7.2 in Warrington, 4.9 in Aston Manor, and 12.6 in St. Helens. No death from small-pox was registered in any part of the United Kingdom. any part of the United Kingdom.

### Society of Apothecaries of London.

The following candidates, having passed the necessary examinations, have received the L.S.A. Diploma of the Society, entitling them to practice Medicine, Surgery, and Midwifery:—W. C. D'Eath, J. M. Fishe, W. N. Pickles, N. S. Shenstone, and S. H.

A RUSSIAN emigrant from the Hague, who intended to sail for New York on March 13th, was attacked by small-pox, and isolated immediately. Prcbably other inmates of the Holland-America Line's emigrants' shelter will undergo quarantine before being allowed to embark.

THERE have been two cases of small-pox in London since a patient was admitted to the Joyce Green Hospital from Camberwell last month. These have occurred in Westminster and Hackney. The latest return shows that two cases now remain in hospital.

### NOTICES TO CORRESPONDENTS. &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a Distinctive Signature or Initial, and to avoid the practice of signing themselves "Reader," "Eubscriber," Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agente. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessary for publication but as evidence of identity.

6d. per line beyond.

Stornowat.—Some of the witnesses before the Departmental Committee upon the Inebriates Acts did not heaitate to assert that it is a penal offence to get drunk, so as to lose control of one's actions. It is a moot point, however, in point of law whether any legal offence is thereby committed, although drunkenness does not excuse a man for wrong-doing when in that state. An important point bearing upon the liberty of the subject is involved, and our correspondent would do well for refer to some legal authority on the subject, say, the Law Journal. The tendency of recent legislation has been in the direction of rendering drunkenness an offence

MR. CLEMENT SERS .- Your letter is unavoidably crowded out of our present issue.

PHARMACIST (Jersey).—Your letter to hand last week regarding the poisonous dose of quinine. In fevers and malaria patients are able to withstand amounts far in excess of the average dose. Curiously, a case was investigated by Dr. Danford Thomas on the 21st inst. at the Marylebone Coroner's Court. The deceased was 56 years of age, a strong and healthy woman, who had taken 25 grains. Death resulted from cardiac paralysis paralysis.

THE WOES OF A HOSPITAL PATIENT.

Hospital patient (bricklayer) recounting his experience to patient in next bed.

Oh, yes, I've been to all the hospitals, St. George's, Bart.'s, and Guy's,
And when I'm out again at work my mates stare with

surprise.

I've had bronchitis, pleurisy, no wonder I am vexed With chilblains and the whooping-cough, I wonder what comes next?

comes next? The jaundice and the dysentery has left me just a wreck, Dyspepsia and the stomach-ache have knocked me off my

peck.
But well I know they'll patch me up, and do their best for me,
Till I get the bloomin' leprosy, and then I'm "up a tree."
A. D.

AN OBSCURE PRACTITIONER.—Your communication unavoidably

A. F. Marsh (Worthing).—The Poor-law Commission take the pessimistic view that "once a casual always a casual, unless there is within the individual some special grit and force of character to emancipate him from his vicious and retentive environment." It seems evident that society is out of patience with the casual tramp, and that some drastic plan for dealing with this unhappy product of our social system must be found. found.

ZOSTER.—You should call on this superseding practitioner, and have the matter out with him in a friendly way. It is a pity to he "touchy." The British public can select its own medical attendants, as long as it does not confuse or mix up two medical

# **EVIDENCE**

N EXPERT comparative analysis of the principal Cocoa preparations reveals the fact that VAN HOUTEN'S is much more readily digested than any other kind.

The remarkably fine state of sub-division of the powder renders it perfectly miscible and no sediment remains in the cup.

VAN HOUTEN'S COCOA is therefore pre-eminently suitable for invalids, and does not tax the weakest digestive organs. It never varies in quality and can be confidently recommended as a nourishing, sustaining, and strengthening beverage of the highest standard of purity.

80 years reputation as "the BEST."

### Notes and Comments.

**Ambulance** Service for London.

THE Committee appointed by the Home Secretary to inquire into the ambulance needs of London issued their Report last week, and we hope that now there will be no delay in

fulfilling what has long been a crying need in the metropolis. That the mighty congerie of cities which we call London, with its thousands of street accidents, should have nothing in which to remove the victims and no means of rendering effective first aid, is a reproach to its civilisation-almost as great as if it possessed no fire brigade. The Committee are unanimous on the establishment of an ambulance service, and on the traction being by motor. They recommend that eight stations should be set up in the administrative county, each with an establishment charge of  $\mathcal{L}_{1,500}$  a year. As to which authority shall undertake the work there is a division of opinion. Sir Kenelm Digby and Lord Stamford favour the Metropolitan Asylums Board, and Sir William Collins, who knows the needs and conditions of London municipal life as few others do, favours the County Council, or, failing them, the police. It is really difficult to accept the majority proposal seriously, as everybody connected with administrative matters knows that the Metropolitan Asylums Board is only marking time till it is absorbed into the County Council.

MOREOVER, if there were no other M.A.B. reason, the fact that the Metropolitan Asylums Board is already the L.C.C. ambulance authority for infectious

cases should preclude it from being endowed with this totally fresh set of duties. To begin with, there would be endless confusion as to which type of ambulance was needed in emergencies, and unless the infectious ambulance stations were entirely distinct from the accident ones, there would always be the risk of infection passing to the latter. There is a great deal to be said for the police being the authority, as it is chiefly through them that accident ambulances would be required, and any complaints could be dealt with directly, and not by circumlocutory letters passing from one authority to another, each, perhaps, a little jealous of the other's powers. On the other hand, the government of London is drifting, and very properly drifting, into the hands of the County Council, which is becoming the Parliament of London. As such it will attract men of high status and greater enthusiasm than many of those who have served on local bodies in the past, men governed by a sense of public duty, and not possessed of axes in need of grinding. There can be no doubt in every mind that every fresh duty pertaining to the whole of London should be assigned to the Council.

The Germ of Trachema.

THE news from Berlin that Professor Greef has discovered the pathogenic organism of trachoma must excite keen interest amongst ophthalmolo-

gists throughout the world. It comes with the weight of authority, inasmuch as the learned Professor is Director of the Berlin University Eye Hospital, and his observations will doubtless be rigorously tested forthwith in many lands. Among the micro-organisms that we may assume underlie many well-marked infective maladies, that of trachoma appeared to be one of the most elusive. The disease runs so definite a course, and is so lingering and so contagious, that it was difficult to account for its natural history on any theory other than that of a specific microbial origin. Some of the best work done in the treatment of school trachoma was achieved years ago in the Central London Schools at Hanwell, where Mr. Sydney Stephenson showed that it was possible to isolate trachomatous children without interruption to their education. At the same time, it was shown that trachoma could be weeded out of Poor-law institutions, and that, however lingering its nature, it was nevertheless curable in the course of time, even if the period were extended over several years. The Hanwell Isolation Schools for Ophthalmia marked a great scientific advance in the treatment of a disastrous disease.

Means.

That the discovery of a specific germ What in trachoma—assuming the feat to the Discovery have been accomplished—must one day bear fruit can hardly be doubted.

If we may judge from the length of time that has elapsed before the demonstration of the organisms of tuberculosis and malaria has led to great preventive results, we may have to wait a long time before any such discovery will lead to the extermination of trachoma. One important state-ment, however, accompanies the news from Berlin, namely, that Professor Greef has ascertained that the infectivity of trachoma is confined to its early stages. If that be true it must materially modify our future attitude with regard to isolation. Meanwhile, we have to await fuller information than that afforded by a brief telegram. In dealing with many specific infectious diseases it is a comfort to reflect that a satisfactory system of prevention and of cure has been arrived at, even in the absence of the full facts of ætiology. In this case we doubt if any more sound and practical plan of facing the problem of school trachoma could be devised than that applied by Mr. Stephenson many years ago at Hanwell.

LAST week, in the Court of Appeal, yet another human calamity was Sunstroke classed by the judges as an accident. 28 The case in question was an appeal Accident. from a decision of a County Court judge, at Southampton, who ruled that the dependants of a sailor who had died of sunstroke off the coast of Mexico were entitled to an award under the Workmen's Compensation Act, the said sunstroke being an accident within the meaning of the The fact of the matter is that the law has got itself so inextricably mixed up on this question of accident that it is impossible to see where these decisions will carry us to eventually. The other day it was held that an agricultural labourer who was struck and killed by lightning whilst engaged in ploughing had not met with an accident, on the ground that the occurrence was an act of God. Few of the most sceptical would dispute this selfevident proposition, but even the most subtle brain would be puzzled to show that a sunstroke is not an act of God, when a stroke of lightning is. It would be a rather amusing exercise to ask a court of highly-placed judges to formulate a definition of an accident based on the particular decisions of all the Courts which have pronounced on the question in the last ten years. We cannot flatter ourselves, however, that they are likely to oblige our curiosity.

Mistura
Ferri
Gallici.
THE medicinal egg, last heard of about two years ago in America, has now reached this conservative country. The discovery has been made by the Daily Sketch of Man-

chester, one of whose young lions had been interviewing the proverbial London doctor. This enterprising youth has been informed by his elusive victim that the eggs of hens fed on iron are especially useful for delicate persons requiring iron in minute quantities. "Several farmers in Surrey (why Surrey?) who have recognised the commercial value of 'iron' feeding, command high prices for their produce from hospitals, sanatoria, and nursing homes." It is perhaps significant of the backwardness of the medical profession in London that they have to learn of these ferruginous eggs from a lay Manchester journal. The method of producing this tonic nutriment, we learn, consists in scattering iron rubbish in the hen-runs and placing rusty nails in the drinking-troughs. We now begin to understand the Admiralty policy of scrapping old battle-ships: it is evidently done with the idea of promoting the national physique by supplying His Majesty's subjects with iron in the surreptitious and nutritious form of the humble and homely egg, but, seriously, we could only wish that this type of journalistic rubbish had no more substantial existence than the iron rubbish it prates of.

### LEADING ARTICLES.

TUBERCULOSIS AND DAIRY FARMS.

ALTHOUGH the essential genius of British preventive medicine lies in its practical nature, there are, nevertheless, times when the chariot-wheels appear to drag somewhat heavily. A delay of that kind is now vexing the soul of the sanitarian in the long-deferred measures for the stamping out of tuberculous cattle in dairy farms. The Royal Commission has spoken out decisively as to the infectivity of bovine tuberculosis, so far as the human species is concerned. Nor is their voice less uncertain as to the spread of tuberculosis, both to

children and adults, through the agency of infected milk. Then comes the practical man who, seeing that a vast amount of tuberculosis is preventable if attacked at its source of origin, namely, the dairy cow, demands that a rigorous control shall be exercised over the public milk supply at every stage of its collection and distribution. The only logical solution, indeed, appears to be the compulsory slaughter of tuberculous cattle. So extensive a destruction of property could hardly be exacted without a scheme for adequate compensation. It is there that the crux of the reform is reached. The nation will be asked to spend a vast sum in exterminating tuberculous cattle, and unfortunately it appears to be almost hopeless at the present moment to expect any great public expenditure upon a purely social matter. Yet the price of a single warship of the Dreadnought type would pay for the destruction of many herds of diseased cattle. Some day or other, when the international race for military and naval supremacy has had its day, the nations of the world will have time to turn their attention to the infinitely more worthy problem of the preservation of life by the elimination of infective agencies inimical to the safety of mankind. Meanwhile, the metropolis, with its enormous milk-consuming population, is at length taking steps to reduce the incidence of milk-borne tuberculosis. The Public Health Committee of the London County Council, in whose hands the matter is entrusted, have recently issued a memorandum as to their operations from October to January last in dealing, under the Council's General Powers Act, 1907, with the milk coming into London, in order to discover any which might The magnitude of their field of be tuberculous. operations may be gathered from the fact that milk is sent from at least twenty-one counties, from all of which numerous samples have been collected at the stations of delivery. The examination of 283. samples during the period under review showed that 22, or 7.7 per cent., were tuberculous. In addition, the bacteriologist reported 52 others which had proved pathogenic to guinea-pigs, but which required a further period of time for identification. The Council's inspector visited 62 farms outside the county of London, and inspected 2,029 cows, of which 74 (or 3.6 per cent.) were suffering from tuberculosis of the udder. In one case in which the examination of a sample of milk taken from a churn at a London railway station had given a positive result, the inspector found that the farmer concerned had obtained his milk from 18 other farms in the district Upon inspection of all the cows (254) at those farms, he discovered 11 (4.3 per cent.) suffering from tuberculosis of the udder. In every case in which a tuberculous udder had been diagnosed, the dairy farmer or his representative had undertaken to sell no more milk from the affected animal. That amount of protection, it need hardly be pointed out, established a great advance in this particular branch of prevention, but it would be infinitely safer were all such cows destroyed. It is reassuring to learn that the rural are falling into line with the urban sanitary authorities. The Committee have been in communication with the local authorities in whose districts infected cattle were found, and they were

informed; that two or three of those authorities had recently appointed veterinary inspectors to deal with the work. That report is encouraging, but it is of course obvious that the greatest care should be taken to select veterinary surgeons competent in this class of investigation, otherwise the object of the whole organisation is likely to be defeated. The London County Council may be congratulated upon the thoroughness with which this particular task has been discharged, and milk consumers upon the additional security they are deriving from the gradual extension of efficient control over the area of production.

## SOME OF THE EFFECTS OF THE WORK-MEN'S COMPENSATION ACT.

An interesting paper has recently been published by Sir John Gray Hill, an ex-President of the Incorporated Law Society, in which he discusses the law of employer's liability. The paper deals with much which is outside the purview of a medical journal, but it also contains many references and much information of interest to the medical practitioner. Of special interest is the author's opinion on a point which has been often raised in these columns, namely, that in view of the conflicting medical evidence so often adduced as to the amount and probable duration of the incapacity to work resulting from an accident, there should be medical assessors appointed to assist county court judges. He further considers that such assessors should be men of eminence, whose reward should be proportionate to the importance of the task which they undertake. Sir John Hill quotes the remarks made by Professor Pye-Smith on the injurious effect which the Act has on the morale and self-respect of the working-man, who, instead of trying to get quickly over his accident and return to his work, seeks to persuade himself and his medical examiners that he is incapacitated for work long after he has actually recovered. Another most important point on which Sir John Hill comments is on the injustice which arises when an injured workman refuses to submit to a surgical operation which would lessen his incapacity for work and which would entail no great risk or suffering, and he points out the necessity of so amending the law that under these circumstances the compensation allowance would cease. At the present time it is possible for an injured workman, first to decline operation, then to commute his weekly compensation allowance for a lump sum as compensation for "permanent incapacity," and then to enter a hospital and have his "permanent incapacity" removed at the expense of the charitable! It must be obvious to anyone except a sentimental humbug that, if it is one man's privilege to obtain compensation from another on the ground of an alleged injury, it must also be the other man's right to ascertain positively, first that the injury really exists, and secondly that it is incurable. It is, however, equally obvious that the Workmen's Compensation Act, as it stands at present, although in many ways a very necessary piece of legislature, in other ways lends itself to a peculiar form of fraud which, if perpetrated under other circumstances, would lead to a criminal

prosecution. Finally, Sir John Hill calls attention to what, if true, is a very unpleasant matter. He says that there is a practice on the part of the speculative solicitor of agreeing with a medical man willing to accept such terms, that the latter shall receive remuneration in respect of his evidence, only if the award is in favour of the plaintiff. It is unnecessary, we hope, to point out that such an arrangement is contrary to all the ethics of the medical profession, that it is a temptation to men to give improper and incorrect evidence, and that any medical man who knowingly enters into it justly forfeits the respect of self-respecting persons.

### CURRENT TOPICS.

#### Destruction of Rats.

THE Society for the Destruction of Vermin has just held its first annual meeting, and the Chairman, Sir James Crichton-Browne, told of the work accomplished during the year. This work seems to have been chiefly of a missionary or educative kind, but he had to bemoan the fact that the interest taken in the subject was still of a theoretical rather than a practical character. There is no reason why this should be the case, if the information garnered by the Society is at all accurate, for, apart from the spreading of disease, it seems that each rat costs the country a matter of a farthing a day, and as there is a rat population of the density of one per acre, the total depredations of these lively rodents amounts to a sum of about £15,000,000 a year. Now, if this at all approximates the fact, it is easy to see that a commercial country like Great Britain would be greatly the gainer if dispossessed of their unwelcome intrusions. In these days of financial tightness at the Exchequer, a Chancellor who could devise some means of securing the total abolition of the pest should soon be able to surmount deficits of the most disconcerting nature without troubling anybody for an increased share of their wealth, whilst the most ardent advocates of a big Navy would have sufficient to provide themselves with a gigantic fleet without troubling the taxpayer at all. Unfortunately, we gather that the experience of the Society agrees with that of the Antipodes in finding that the bacteriological methods of decimation are not to be relied on in their present stage of evolution, though it may be thought that salvation lies in that direction. We are all against the rat in theory, but is it quite certain that if he were exterminated some worse thing might befall us?

### The Post Office and Re-vaccination.

MR. Buxton has allowed candidates for the Post Office service to be excused re-vaccination on joining, on making a statutory declaration that they conscientiously believe vaccination would be prejudicial to their health. No doubt he has been hardly pressed by faddists of the type of Mr. Lupton, but we cannot but consider that he has shown himself lamentably wanting in backbone in relaxing the regulation. The question is quite different from that of infantile primary vaccination. No one is compelled to join the postal service, and such

as do are persons of mature years and good health. We are sure that no candidate vaccinated secundum artem with glycerinised lymph has suffered more than the pangs which everybody suffers from this trivial operation, and the objection is a purely sentimental one excited and fanned by the crassly-stupid and crassly-ignorant. Moreover, the Post Office is a national distributing agency, and small-pox is undoubtedly capable of being disseminated by formites, so that in time of epidemicity of the disease, if the employees avail themselves at all largely of the relaxation, a considerable number would render themselves liable to contract it, and not only to contract it themselves, but to pass the infection broadcast through the community. It is regrettable that a man of Mr. Buxton's ability and character should so weakly yield to the obstreperous few because they make themselves a nuisance, when there is no real demand for the abolition of a salutary regulation designed to preserve the public health.

### Taxation of Births, Deaths, and Marriages.

Now that methods of "raising the wind" are exercising the minds of the community, and each class is shivering lest his be the henroost to be visited, the Daily Chronicle aptly reminds us that for eleven years, namely, from 1695 to 1706, births, deaths, and marriages were subject to taxation. The population was ranged into various grades of prosperity, and the tariff fixed accordingly. The duke figured at the top of the tree and the proletariat at the bottom, the doctor being regarded as the mean between the two. The birth of a duke's son rendered the parent liable to a fine of £30, a cook's son cost but 2s., while a similar offence on the part of a doctor produced £,1 2s. to the Exchequer. Marriage cost the respective parties £50, half-a-crown, and £5, while a duke had to pay £50 for the privilege of leaving the world, and the poorest subject had to find 2s. for following his example. Our contemporary adds: "One pities the poor doctor, who seems to have been held responsible for other people's births and deaths, as well as his own marriage." We agree, but it only shows that erroneous ideas about doctors' incomes is not a tree of modern growth only. We suggest that those who lament the fall in the birthrate should reverse the above process, and urge the State to pay a bounty to the doctor for each citizen he brings into the world.

### Insanitary Condition of Irish Schools.

We referred recently to the shocking condition in which many of the primary schools in Ireland are kept. The same subject has engaged the attention of the Council of the Dublin Sanitary Association, who have passed a resolution that no adequate and permanent improvement can be expected until the system of medical inspection of school children recently adopted in England be extended to Ireland. We know of no reason why the Act was limited to England, and we trust that in the near future a similar measure can be made to apply to Ireland. But in the meantime we believe that much could be done to improve matters. Even without the medical inspection of children, the condition of the school buildings could be remedied. We believe that it is

within the power of the Board of National Education to refuse to recognise schools which are not housed in proper buildings. If this were done, many of the dens at present in use would be closed. We repeat, without hesitation, that it would be better that children should remain without education than that they should be forced to congregate in hovels which breed disease, and where they learn to be accustomed to, and to tolerate, fifthy conditions.

Remuneration of Surgeons and of Veterinary Surgeons.

A curious contrast, indicating, we may believe, the relative value put on their services by the public, was brought out by Mr. Gladstone the other day, in stating the remuneration paid under analogous circumstances to medical men and to veterinary surgeons respectively. In answer to a question as to the fees paid by the Home Office through the police for attending casualties in the streets, it was stated by the Home Secretary that the fee paid to a medical man was three shillings and sixpence, whereas the fee paid to a veterinary surgeon was ten shillings and sixpence. It would seem, therefore, that one veterinary surgeon is valued as equal to three medical men, or is it that one horse is worth three men? Moreover, Mr. Gladstone was of opinion that the medical men in question received "adequate remuneration." We do not blame Mr. Gladstone or the Home Office authorities. They naturally pay the smallest fee for which they can obtain the services required. If it pays medical men to take such work there is no more to be said. It is, however, an instructive example of the results of the overcrowding of the profession. We would strongly advise intending medical students to turn their attention to veterinary medicine. They will receive better remuneration, and doubtless also be esteemed more highly in the community.

Consent to Operation.

THE Supreme Court at Leipzig has laid down that a surgeon who operates on a patient without the patient's consent or the consent of the patient's legal guardian commits the crime of inflicting bodily harm. The case in which this ruling was given was one in which a surgeon at a Berlin hospital operated on a child without asking the permission of the parents, or notifying them that an operation was going to be performed. This judgment establishes a precedent which settles the question as far as Germany is concerned. Moreover, it has been held that an operation performed without the consent of the patient or the patient's legal guardians is wilful bodily injury, an offence which is punishable by imprisonment. The Supreme Court has ruled that in a case where a surgeon operates without permission, being under the impression that consent has been given, he is also guilty of bodily injury, but that extenuating circumstances may be granted to him on the ground of good faith. Of course it is proper that parents or guardians should be consulted as to operations. but in case of emergency, when a surgeon has to act on his own judgment without such consent, the position is very serious in the light of this We, in England, happily, have not ruling. reached this pitch of legal inelasticity.

Bakers and Bad Eggs.

From time to time accounts are published of the prosecution of a baker having on his premises eggs unfit for human consumption. It is a curious fact that, however had the eggs, the pastry in which they have been incorporated shows little or no trace of their undesirable presence. Presumably the volatile products of putrefaction have been driven off by the heat of the oven; what remains of the albuminous substance is at the same time coagulated, and it is to be presumed that the majority of the bacteria present are incontinently destroyed, otherwise the effects of introducing such pestilential stuff into the human stomach might be disastrous. It may be remembered, however, in this connection that among the Chinese the rotten egg is esteemed a luxury, and forms a bonne bouche of which the Western visitor is expected to partake when invited to dine at the house of a mandarin. But whatever the ultimate scientific finding of the laboratory may be with regard to the precise hygienic position of rotten eggs as an article of food, the average citizen of the Western sphere will heartily endorse the action of the London magistrate who, in a case of the kind recently brought before him, remarked it was a mercy the sanitary inspector went into the bakehouse, and fined the culprit £15 and costs. Unhappily for the future welfare of the cakeconsuming public, the worse the eggs the better the glaze that can be made therefrom.

### PERSONAL.

THE PRINCE AND PRINCESS OF WALES paid a surprise visit to the Middlesex Hospital on March 22nd, and spent two hours in the institution. Their Royal Highnesses, who were accompanied by Prince Francis of Teck, one of the vice-presidents of the hospital, were conducted over the institution by the secretary-superintendent, the lady-superintendent, and the resident medical officer. A visit was made to the Cancer Research Laboratories, where the Prince and Princess showed great interest in the researches—especially those in connection with radio-activity in cancer, the lines of which were explained to them by the director, Dr. Lazarus-Barlow.

PRINCESS VICTORIA OF SCHLESWIG-HOLSTEIN opened the annual exhibition of the Royal Amateur Art Society, at 16 Grosvenor Place, on March 25th. The proceeds of the exhibition will be devoted to the East London Nursing Society and other charities.

THE DUKE OF WELLINGTON presided at the annual meeting of the Brompton Consumption Hospital on March 19th. Lord Cheylesmore moved the adoption of the report for 1908, which shows an increase in the grants to the hospital from the King's Fund and the Hospital Sunday Fund of £3,500 and £3,420 respectively. The committee regard this as in a large measure due to the remarkable success which continues to result from the special form of treatment by graduated exercises carried out at the Frimley Sanatorium

GENERAL SIR J. RAMSAY SLADE, R.A., has been elected chairman of the Committee of Management of the Italian Hospital, Queen Square, W.C.

Surgeon-General George D. Bourke, C.B., has been appointed an honorary physician to the King, vice Surgeon-General T. Tarrant, C.B., deceased.

MAJOR RONALD Ross, C.B., F.R.S., returned last week from an important mission to India, on which he was sent by the Liverpool School of Tropical Medicine.

THE new out-patient department of the Royal Boscombe and West Hants Hospital will be opened by H.R.H. the Duchess of Albany on Saturday, April 3rd.

DR.: SAMUEL GREFITH, M.D., of Bodlondeb, Portmadoc, a prominent Freemason, who died on 1st December, aged 77, left estate of the gross value of £10,161, with net personalty £4,903.

DR. G. F. BUCHAN, M.B., D.P.H., Deputy Medical Officer for the city of Birmingham, has been appointed medical officer of health for the district of Heston and Isleworth, Middlesex, in succession to Dr. E. Steegman.

AMID cheers from both sides, the Ottawa House of Commons last week unanimously accepted a gift of £50,000 from Lord Strathcona for the furtherance of the scheme for the physical training of the school children of Canada. The annual sum to be devoted to this purpose is £2,000.

Dr. Bonnje. Senior Medical Officer of the Russian Squadron which was entertained last week in London by the Admiralty, and seven other Russian medical officers lunched with Inspector-General T. D. Gimlette and the officers of Haslar Hospital on March 17th. The Russian officers were afterwards shown over the hospital.

THE Mayor of Marylebone (Colonel Alderman A. J. Hopkins) presided, on March 22nd, over the annual meeting of the Marylebone Health Society, held in the Town Hall. Dr. Meredith Young, Medical Officer of Health of the borough, and Dr. A. Newsholme, Medical Officer of the Local Government Board, were among the speakers.

THE annual council of governors of the Great Northern Central Hospital was held on March 18th, under the presidency of Sir John Dickson-Poynder, M.P. (chairman of the committee of management). The Chairman stated that there was a deficiency on the past year of £4,643, and at the present time an indebtedness to the bankers of £10,304.

THE eighth International Congress of Hydrology and Climatology, including geology and physical therapeutics, will be held this year at Algiers, from April 4th to 10th, under the patronage of the Governor-General of Algeria. The local secretaries for Great Britain are Dr. G. Pernet and Dr. Purves Stewart, 94 Harley Street, London, W.

THE 136th Anniversary Dinner of the Medical Society of London was held on March 10th at the Hôtel Métropole, under the chairmanship of Mr. C. B. Lockwood, F.R.C.S., the President of the Society for the current year. Among the speakers were Sir William Church, President of the Royal Society of Medicine, Sir Alfred Keogh, and Dr. J. Kingston Fowler.

THE Northumberland and Durham Medical Society held their annual dinner on March 18th, at the Royal Turk's Head Hotel, Newcastle, when Dr. R. S. Peart (President) was in the chair, and the principal guest was Sir Lauder Brunton, Bart., F.R.S. Among others present were the Lord Mayor of Newcastle (Ald. J. J. Forster), Prof. Sir George Hare Philipson, Prof. Sir Thomas Oliver, and Dr. G. H. Hume.

THE West African Section of the London Chamber of Commerce gave a complimentary dinner at the Criterion Restaurant on March 18th to Professor W. J. H. Simpson, M.D., F.R.C.P., on his return from West Africa after his investigations, on behalf of the Colonial Office, into the existence of plague and the sanitary measures in force there. Sir Ralph Moor, Chairman of the Section, presided, and the company included Mr. Charles Charleton, Sir William Church, Sir Patrick Manson, F.R.S., Sir Shirley Murphy, and Sir Roper Parkington.

### A CLINICAL LECTURE

ON THE

# TREATMENT OF LOCAL TUBERCULOUS LESIONS BY INJECTIONS.

By Prof. A. CALOT, M.D.,

Physician to the Berek Institution, Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

EXTERNAL localisations of tuberculosis are, by common accord, amenable to three kinds of treatment: operative, expectant, and by injections, and there are many reasons for asserting that the lastnamed is far and away the best. Operation is to be discarded, for it rarely effects a cure and it is always very disfiguring. The conservative treatment without injections is, on the whole, preferable to operation, but it is too uncertain; it yields unsatisfactory results in half the cases, and it is too protracted, since it takes from three to five years.

The treatment by injections, on the contrary, always, or almost always, effects a cure (in 99 per cent, of the cases), and this in a comparatively short space of time—a few months at the outside—and it leaves no disfigurement. Moreover—and this is no small advantage—it is benign, easy of execution, and can be carried out by anyone.

In order to yield these highly satisfactory results, however, the treatment must be applied sec. art. It must be done in a particular way and in no other; we must employ a particular medicated solution and no other, in prescribed doses, the injections to be made at stated intervals, and so on.

If it be done anyhow, the result will probably be disappointing so I will now describe the technique.

disappointing, so I will now describe the technique.

Instruments.—Three instruments only are necessary: (1) Needles, a series of four, corresponding to Colin's Nos. 1, 2, 3 and 4. Nos. 1 and 2 are used for injections without previous puncture, that is to say, in dry tuberculosis. Nos. 3 and 4 are used in cases in which injection is preceded by puncture—i.e., in suppurating tuberculosis. (2) An aspirating syringe. (3) A sterilisable syringe of any kind. We may add a tube of chloride of ethyl for local anæsthesia.

The Fluid for Injection.—There are numerous formulæ for this, but the two following will suffice for all cases.

The first is a mixture of iodoformic ether and creosoted oil in the following proportions:—

Liquid vaseline, 75 grammes; Ether, 25 grammes;

Creosote, 5 grammes; Iodoform, 10 grammes.

The second is a mixture of camphorated naphthol and glycerine:—

Glycerine, 15 grammes;

Camphorated naphthol, 3 grammes.

The latter requires to be beaten up in a mortar or well shaken for a minute or two, so as to make a homogeneous fluid, miscible with water. We must make sure of this before each injection by allowing a drop to fall into water. If the drop does not disappear in the water, some more glycerine must be added and the mixture again shaken up. Chemists dispense camphorated naphthol more or less clear, so that the quantity of glycerine required varies somewhat.

The indications for one or other of these formulæ may be deduced from the fact that the first is sclerosing, while the second is resolvent. Conse-

quently, when the lesion is suppurating and the abscess is quite ripe, we make use of the first, while, if the abscess is not ripe, or if the liquefaction of the granulations is only partial, we make use of the second, which will precipitate the liquefaction, though even in this case we wind up by one or two injections of the creosote-iodoform mixture.

The Dose.—The dose of either mixture is from 2 to 12 grammes, according to the patient's age, and, to some extent, to the size of the tuberculous focus. About ten injections are usually necessary, given at intervals of four or five days, as a rule. The injections should be made into the tuberculous focus, and not in the neighbourhood.

We will take a case of suppurating tuberculosis, a cold abscess, a softened cutaneous gumma, a suppurating adenitis, a synovitis, cr a white tumour with effusion, a congestive abscess, no matter. We must evacuate some of the fluid before making the injection. For this purpose we make use of a No. 4 needle, which is connected up with the aspirator. When we have completely emptied the abscess the aspirator is disconnected, and the needle, which has been left in situ, is adapted to the syringe containing the fluid for injection.

Two observations may here be made—viz., that it is not always advisable to make an injection directly after evacuation of the abscess contents. For instance, if the skin over the abscess is much stretched, it is undesirable to inject at once, since we should run the risk of further damaging the skin. In such cases it is preferable to repeat the punctures at short intervals, say, every two days, or even daily, should that appear necessary, to prevent the skin giving way under the eccentric pressure of the contained fluid. The puncture is made in a different spot each time in order to damage the skin as little as possible. As soon as the skin has recovered tone, we proceed with the injections to the number of ten.

The second observation is, that at the end of the course, after the tenth injection, we must make two punctures at stated intervals, not followed by any injection. At this stage the abscess wall is only secreting a non-virulent serum, but this secretion might go on indefinitely if we continued injecting the modifying fluid, which is always more or less registing.

less rrritating.

In order to dry up the secretion, it is well at the end of the treatment to apply methodical pressure by pads of cotton wool and crêpe bandages, hoping by this means to bring the abscess walls into apposition. When the tuberculous lesion is dry or fungous, as in a cutaneous tuberculome, a hard gland, an epididymitis, a fungous arthritis, &c., our object is either to effect a sclerous transformation of the granulating tissue or its liquefaction.

To determine sclerosic, we inject the mixture of creosoted iodoformic oil in doses of from 2 to 8 grammes, according as the patient is a child or an adult. The injection is made into the centre of the fungating mass, and is repeated every three or four

days until ten have been given. Then the region is compressed with pads of cotton maintained by a crêpe bandage.

It is to be borne in mind that the desired sclerosis does not take place either during or immediately after the injections. On the contrary, the glands injected remain swollen, and it is not until three or four weeks after the last injection that they begin to diminish in size, and they do not quite disappear for from three to five months.

When we wish to bring about liquefaction of the contents we inject the mixture of camphorated naphthol and glycerine in doses of from 1 to 5 grammes, according to the age of the subject. In this particular case we must repeat the injection daily until the gland has broken down. By the fourth and sixth day some elasticity or even fluctuation may be perceived at the centre of the tumour, a sign that liquefaction is taking place. As soon as that is the case we puncture, and then inject; but thenceforth we need only make two injections a week until ten injections have been made (from the time of the liquefaction).

Which are we to aim at, sclerosis or liquefaction? Well, speaking generally, liquefaction is preferable, for the cure is more certain and more radical. On the other hand, the reaction to the resolvent injections of camphorated naphthol is sometimes rather intense and distressing, so that for patients who are not in a hurry, and in private practice, I advise recourse to injections of creosoted iodoformic oil, which suffice in 75 per cent. of the cases. Should it prove otherwise, we can always fly to the cam-

phorated naphthol as a last resource. There is always—and there ought to be—a certain reaction whichever fluid we employ, but this reaction is much more pronounced with camphorated naphthol, especially when we have to repeat the injection daily. This reaction does not immediately follow the injection, and is manifested by general and local symptoms of ordinary subacute inflammation, a sort of "tepid abscess," so to speak. The temperature may go up to 990, 1010, or even 1020 F., with the doses recommended above. It is possible, however, to control this reaction without sacrificing the effects we wish to obtain-viz., the liquefaction.

If, after the first or second injection, the temperature goes up it is a good sign, in that it indicates a speedy action, but the pain and other symptoms must not be allowed to go beyond a certain measure, nor the temperature allowed to remain for more than a few days at 1030 F. With this object in view, we only have to suspend the injections for a day or two, or else inject somewhat smaller quantities. Still, it must be borne in mind that a certain reaction is indispensable, and we must aim at obtaining what is required, and no more.

The Technique for Special Organs.—The instructions enumerated above are applicable in general to external tuberculous lesions, wherever situated. We will now discuss their application in sundry special cases: enlarged cervical glands, tuberculosis of the testicle, and of the epididymis. We shall then add a few remarks on the anatomical facts that must guide us in injecting joints and congestive abscesses in Pott's disease.

Cervical Adenitis.-These should never be extirpated, for here, more than elsewhere, surgical intervention leaves disfiguring scars without affording any security against recurrence. If the gland has broken down, it is dealt with by puncture, as described above, and a cure can be obtained in six or eight weeks without any scarring. If the gland be hard it is preferable to cause it to break down. with which object in view we inject daily into the centre of the gland 20 drops of the naphthol solution. By the fifth day there will be fluctuation, whereupon we proceed with the punctures and injections at intervals, just as in the case of spontaneous suppuration.

Tuberculosis of the Testicle and Epididymis.— Here again operative intervention gives disastrous results; it rarely cures and always mutilates, and what mutilation! Early in my professional career I used to operate, but for the last fourteen years I have altogether abandoned castration, and have had recourse exclusively to injections. Out of 116 cases in children and adults I have not to record a single instance of failure. These statistics comprise not only cases of testicular and closed epididymal tuberculosis, but also many fistulous cases to the extent of a fifth of the total number. The cure took from two to four months for unopened lesions, and from three to ten months for the others.

Just as in the case of tuberculous glands, we have to choose between sclerosis and breaking down, but on account of the peculiar susceptibility of the integument, and especially when we are dealing with lesions close to the skin, I advise the sclerosing treatment (creosoted iodoformic oil) in preference to the naphthol solution, which causes liquefaction. If suppuration has taken place we have recourse to

punctures and injections, as for glands.

There is a third group of cases in which hydrocele is symptomatic of tuberculous lesions of the testicle or epididymis, and in these we must make the injections and punctures right into the tunica vaginalis itself, as if we were dealing with an ordinary cold abscess. In five cases out of seven we have effected a cure by this treatment of tuberculosis of the neighbouring epididymis without attacking it directly. In the two other cases we had to inject the epididymis directly, and this proved successful.

Intra-articular Injections.—Not only articular tuberculosis, but all forms of arthritis or osteoarthritis, whether rheumatic, gouty, blennorrhagic, dry arthritis, &c., are amenable to intra-articular injections, the solution varying according to the nature of the lesion. It is therefore indispensable to be quite familiar with the puncture points for

each joint.

Upper Limb.—The shoulder is attacked from the front, taking the coracoid process as our guide. The bony prominence is easily identified, even in stout subjects, below the outer fourth of the clavicle. It forms the antero-external angle of the bony arch of the shoulder (acromio-coracoid arch). The needle is thrust in at a spot a third of an inch outside this process, from before backwards and slightly from above downwards, pushing the needle until it meets with bone. This is the head of the humerus covered with its cartilage, and we know that we are inside the joint cavity. We have only to withdraw the needle a trifle before making the injection.

The Elbow.—This joint may be entered from outside or from behind—i.e., through the humeroradial interline, to be felt at the external border of the elbow, while the forearm is being rotated, or well above the tip of the olecranon over the subtricipital cul-de-sac of the synovial membrane of the joint. The latter plan is to be preferred, since it gives us more room.

The tricipital cul-de-sac is readily accessible, especially when the forearm is flexed. We have only to thrust the needle in a third of an inch above the tip of the olecranon in the middle line, pushing it in until we meet with bone, when we know that

we have entered the cavity.

The Wrist.—It is not quite so easy in the wrist, but it can be effected with certainty if due care be taken to conform to the directions. The joint must be attacked from behind. The middle of the interline is a quarter of an inch above the middle of a line drawn between the two styloid processes of the ulna and radius, which are always easy to recognise. The needle is then pushed in a quarter of an inch above this line, using a fine needle, the patient's hand being strongly flexed so as to open the intervening space. In arthritis of the wrist, synovial pouches are often visible on the back of the wrist, and all we have to do is to insert the needle into one of these prolongations.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by James Sherren, F.R.C.S., Assistant Surgeon to the London Hospital, Surgeon to the Poplar Hospital for Accidents. Subject: "Duodenal Ulcer, its Diagnosis and Surgical Treatment."

### ORIGINAL PAPERS.

### DEATH CERTIFICATION AND CORONERS' INQUESTS.

By FREDERICK W. LOWNDES,

Surgeon to the Liverpool Police.

Two Acts of Parliament, the Births and Deaths Registration Act of 1874, and the Coroners' Act, 1887, have been very prominently before the medical profession and the public for some years past, and especially during this present year. The first of these Acts made the certification of deaths compulsory on all medical practitioners attending patients in their last illness. The 20th clause of this Act is as follows:-

"In case of the death of any person who has been attended during his last illness by a registered medical practitioner, that practitioner shall sign and give to some person required by this Act to give information concerning the death, a certificate stating, to the best of his knowledge and belief, the cause of death, and such person shall, upon giving information concerning the death, or giving notice of the death, deliver the certificate to the registrar, and the cause of death as stated in the certificate shall be entered in the register, together with the name of the certifying medical practitioner.

Before this Act was passed and became law on the 1st January, 1875, certificates were given, a refusal to give one generally leading to police inquiries, and the reporting of the case to the coroner of the district. This giving of certificates has always been an unpaid and most thankless duty. The clause of the Act of 1874 which I have given is most important for many reasons, and should be well known to every practitioner whom it concerns, from house surgeons or physicians to the oldest and most experienced practitioner. It will be seen that it protects every medical practitioner from giving a certificate of the cause of death unless he has attended the deceased (presumably for a reasonable interval before the death), and also that the death is one from natural causes, and one which the registrar can register without hesitation. Every practitioner who gives a certificate of the cause of death should remember the old saying, "Litera scripta manet," and that his name will be indelibly recorded in the register. It was not so before this Act was passed, and it is a remarkable coincidence that in the last edition of the late Dr. Taylor's

manual on "Poisons" I find the following sentence: "Gastric fever." It could scarcely be supposed that a case of antimonial or of arsenical poisoning should be mistaken for this disease. The case of Mary Ann Cotton (Reg. v. Cotton, Durham Lent Assizes, 1873) shows, however, that such a mistake may be made, not only in one, but in a series of suspicious cases. One out of three husbands and four of her children died rather rapidly one after another, with symptoms of irritant poisoning, proved by the exhumation and examination of their bodies to be owing to arsenic. Gastric fever was certified by the medical man to be the cause of death. Under such a perfunctory mode of registering causes of death, it is not surprising that this woman succeeded in destroying by poison twenty persons before her crime was discovered. Though thirty-four years have passed since the conviction and execution of this wretched murderess, I remember well the sensation it caused. Her victims comprised three husbands, fifteen children, her mother, and a lodger. She had married a fourth husband, who found out that she had insured his life behind his back, and decided to leave her. It is a terrible and, I hope, a unique instance of a woman marrying husbands and bearing children, only to poison them for the most sordid of motives.

Thirteen years later the Coroners' Act was passed, receiving the Royal assent 16th September, 1887, and at once becoming law. It repealed many very ancient statutes, including one of 1 Edward III., stat. 1, c. 8. This required the coroner to go to the place where any be slain, or suddenly dead or wounded, to summon a jury, and to inquire as to the cause of death. Acting upon this, coroners claimed the right to hold an inquest in any and every case of sudden death, though its cause was perfectly well known to the relatives and medical attendant. The 3rd section of the Act now in force defines, with some approach to perfect accuracy, the deaths which should form the subject of an inquest. It, as well as the 20th clause of the Registration Act of 1874, should be well known and carefully studied by every medical practitioner, to learn when he can give a certificate of the cause of death, and when he ought to refer the cause to the coroner.

"When a coroner is informed that the dead body of a person is lying within his 'jurisdiction,' and there is reasonable cause to suspect that such person has died a violent or an unnatural death, or has died a sudden death of which the cause is unknown, or that such person has died in prison, or in such place or under such circumstances as to require an inquest in pursuance of any Act, the coroner, whether the cause of death arise within his jurisdiction or not, shall, as soon as practicable, issue his warrant for summoning not less than twelve or more than twenty-three good and lawful men to appear before him at a specified time and place, there to inquire, as jurors, touching the death of

such person as aforesaid."

Now, a coroner's court has been called one of "first instance," and it is very important he should be informed promptly of every death comprised within the section just quoted. Sudden deaths are followed by rapid decomposition, especially in hot weather; so are violent or unnatural deaths occurring under similar circumstances. Hence the importance of his being informed of each of these by him who alone is competent to give a correct opinion-the medical attendant in the last illness, or who has first seen the body after death. For a violent death includes one in which death may not have occurred till a long time after the violence. A legal tradition gives one year and one day as a limit. But this is a matter for the coroner to

decide, it being for him to judge what is "reasonable cause to suspect," etc.

In sudden deaths of which the cause is well known to the medical attendant of the deceased as being due to natural causes, such as heart disease, apoplexy, epilepsy, Bright's disease, diabetes, etc., he can inform the coroner and so avoid the necessity for an inquest. For although this important section does not make it compulsory on the medical attendant to inform the coroner of the death and of its cause, it is very desirable that he should do so, and that all medical practitioners should work with the coroner and not against him. Reference to a coroner does not mean that an inquest must follow, since he has power to make an informal inquiry, and may send to the registrar what he believes to be the cause of death. For although the vagaries of some coroners have of late been such as to revive the old taunt of "crowner's quest law," yet it must in justice be admitted that coroners have reason to complain of the carelessness of some medical men in giving certificates contrary to the law as defined by the two Acts before us. A very gross instance of this occurred towards the close of 1891. A woman named Matilda Clover, belonging to the unfortunate class, died in a brothel in London. A man named Neill or Cream had accompanied her home and passed some hours with her. He was heard to bid her good-bye and to leave the house. Some hours after she was heard screaming, and was found to be in violent convulsions and in great agony, in which she died. No registered practitioner saw her till after her death, when a surgeon who had attended her some time previously for intemperance came at the request of the brothel-keeper and saw the dead body. He filled up the usual form of certificate, stating that he last saw her when he saw not her but the dead body. He gave the cause of death as chronic alcoholism, the symptoms being totally different. One mistake often leads to another, and so it was here. The brothel-keeper registered the death, informing the registrar that she was present at the death, which was false. The registrar registered the death, instead of reporting it to the coroner as it was an unnatural death. Only a week previously another prostitute had been poisoned by strychnine by the same man, and the police were in search of him. Six months later two more prostitutes were poisoned by the same man with the same poison. The body of Matilda Clover was exhumed and examined, strychnine being found. Had the surgeon who certified to her death as due to chronic alcoholism refused to certify at all, and informed the police, he would have been instrumental in arresting the career of this murderer and, humanely speaking, he might have saved the lives of two other women. It is satisfactory to record that in three out of the four cases the cause of death was promptly and correctly diagnosed, and after a long trial the murderer was executed. This case attracted much excitement, and our registration system was condemned, but unjustly so. not the system, but the conduct of all the three persons who acted in violation of what was the plain duty of each.

A Select Committee of the House of Commons was appointed in 1893, under the chairmanship of Sir B. Walter Foster, then Secretary to the Local Government Board, to inquire into the sufficiency of existing law as to the disposal of the dead, for securing an accurate record of the causes of death in all cases, and especially for detecting them where death may have been due to poison, violence, or criminal neglect. Sir Walter Foster was aided by very able colleagues; witnesses of the highest stand-

ing in the medical profession attended to give evidence. The inquiry was a most exhaustive one, and the Bluebook containing their report, with the minutes of evidence, can be obtained for a very small sum, and will well repay perusal. Their principal recommendations were:—

That no death should be registered without a medical certificate or by a coroner after inquest.

That medical practitioners should verify the death of each person whose death they certify.

That the same form shall be used by every medical practitioner.

That the practice of burial in pits or common graves should be discontinued.

That still-births which have reached the development of seven months should be registered.

Fifteen long years have passed since these recommendations were made and others which I have been obliged to omit, but nothing has been done except two alterations in the form of medical certicate furnished by the Registrar-General. has now a letter and number, and so can be traced. Each has the word "alive" printed after "I last saw h——." It must be humiliating to the overwhelming majority of the medical profession that it should be necessary for any member to be taught that a dead body and a living person are not identical. A Bill has been drafted, and may become law during the present session of Parliament, to abolish the compulsory viewing of dead bodies by coroners' juries. If one may judge from reports of inquests in the daily press, the abolition of coroners' juries altogether would be a welcome change. Any member of the House of Commons who would bring in such a Bill and carry it successfully through, would earn the lasting gratitude of the thousands of men who now have to leave their occupation and spend hours and days at inquests to perform a most disagreeable and wholly unnecessary duty. There is no coroner's jury in Scotland; the procurator-fiscal makes his inquiry with the aid of the medical attendant or some other surgeon, gives his order for the burial, and the utter farce of twelve good and loyal men to decide what can be done by one is dispensed with. That it is not per-fect may be admitted. The Ardlamont and Carlisle poisoning cases show this. But our adoption of it in England and Wales, with such modifications as might suggest themselves, might well be considered. The Births and Deaths Registration Act ought to be amended to make it harmonise with the Coroners' Act. This also requires amendment to suit the requirements of the medical profession, who justly demand remuneration from the coroner for information given which makes an inquest unnecessary, also for attendance at adjourned in-quests, and more liberal fees for attendance and necropsies.

# PROGNOSIS IN VALVULAR DISEASE OF THE HEART. (a)

BY SIR JOHN F. H. BROADBENT, BART., M.D., F.R.C.P.,

Physician to Out-Patients, St. Mary's Hospital; Physician to the Hampstead General Hospital, &c.

THE subject of prognosis in heart disease is one of the first importance to both physician and patient. The latter will wish to know not merely whether he is in danger of sudden death, but what are his prospects as to the future, and how best he may regulate his mode of life, exercise, diet, etc., so as to give himself the best possible chance. The physician is required, therefore, not merely to make an accurate

(a) Bend before the Section of Medicine in the Reyal Academy of Medicine in Ireland, Friday, February 28th; 1909.

diagnosis of the nature of the affection, but to forecast what effect it is likely to have in shortening the patient's life, and in limiting the sphere of his To do this he must have a clear idea as to the relative danger attending the various valvular lesions, and also some method of estimating the extent of the lesion.

In 1884 my late father delivered before the Harveian Society the Harveian Lectures on "Prognosis in Val-vular Disease of the Heart," in which he laid down certain rules for guidance in prognosis, based on the structural changes in the heart and vascular system, which take place as a result of the lesion, pointing out how an approximate estimation of the extent of the lesion could be arrived at from the degree of structural change to which it had given rise.

There are, of course, many other points which must be taken into consideration, such as the age and family history of the patient, the ætiology of the lesion, whether due to acute endocarditis or chronic degenerative change, the character of the murmur, and the degree to which it replaces the sound it accompanies, etc. These will be dealt with seriatim in the discussion on the different valvular lesions.

Reserve Power of the Heart.—In the healthy heart

there is an enormous reserve power which enables it to respond to the increased demands entailed by exertion and exercise without any ill effect. This reserve power is diminished if one of the valves be damaged, even though compensation has taken place, in proportion to the extent of the valvular lesion. If the heart be taxed beyond the limit of its reserve, warning symptoms, such as dyspnœa, etc., will set in, and if the exertion be persisted in in spite of these, breakdown of compensation and serious damage to the heart may result.

AORTIC INCOMPETENCE.

In discussing the question of prognosis in aortic incompetence, we must draw a sharp line between that which results from acute endocarditis in the young, and that which is due to degenerative changes which affect the root of the aorta or its valves in later life. In the former, a lesion once established does not increase in severity, but the cicatricial con-traction which occurs in the process of repair will tend rather to limit than increase the incompetence. In the latter the incompetence is commonly due to dilatation of the root of the aorta, to which the valves are attached, from weakening of its wall by athero-matous degeneration, and this is likely to be pro-

We will now consider for a moment the consequences of aortic incompetence. Immediately after the closure of the semi-lunar valves the elastic recoil of the aorta drives back into the ventricle an amount of blood which will vary in proportion to the degree of incompetence of the valves. The ventricle is in diastole, and blood is being poured into it from the left auricle; in addition to this, blood is forced back into it under pressure from the aorta. In its relaxed condition it is unable to resist the over-distension, which is a consequence, and it gives way under the strain and dilates. As it has to propel a greater volume of blood, and resist, as far as possible, excessive distension by the regurgitant stream, it is essential that its walls should be strengthened, and we find that under favourable circumstances hypertrophy of the left ventricle, in process of time, takes place.

The degree of hypertrophy is, as a rule, proportionate to the degree of incompetence, and in prognosis is of great importance as one of the means of esti-mating the extent of the lesion. Certain qualifications

are, however, necessary.

(1) In the first place, in this, as in all cases of endocarditis due to rheumatism, we must bear in mind that it is not the valves alone which suffer, but that the heart muscle seldom escapes damage. In proportion to the degree of myocarditis, there is loss of tonicity of the heart muscle, and a corresponding ten-dency to dilatation, which may be extreme even in the absence of a valvular lesion, as we see in some cases of pericarditis. If, therefore, we have in addition to an aortic lesion a severe degree of myocarditis, the initial dilatation may be out of all proportion to

the degree of incompetence, as will also be the hyper-

trophy that ensues if a patient recovers.
(2) If the patient gets up too soon and goes about before sufficient time has elapsed for the structural changes necessary for compensation to take place, the degree of dilatation and hypertrophy which ensue may be out of proportion to the lesion.

(3) If the patient has passed the age of adolescence when the lesion occurs, it is improbable that the requisite degree of hypertrophy will ensue, as regeneration of muscular tissue does not occur to any extent in later life.

The Pulse.-The most remarkable feature in the pulse is the collapsing character, to which attention was first drawn by Corrigan, due to the loss of sup-port to the column of blood in the aorta on its elastic recoil, and consequent sudden fall of pressure en-tailed by the leakage through the incompetent valves. This is more marked when the arm is held in the vertical position. It is proportionate to degree of incompetence of the valves, and hence constitutes an important criterion in prognosis as one of the indica-tions of the extent of the lesion. The large size of the arteries and relaxed condition of the arterioles are also remarkable, and it would appear that this is a protective measure against overstrain by the increased volume and greater force with which the blood is projected by the hypertrophied and enlarged heart into the arterial system. The size of the artery,

therefore, is of important prognostic significance.

The Symptoms.—The symptoms are mainly those of deficient blood supply in the systemic circulation consequent on the ill-sustained blood pressure. Pallor of countenance, a tendency to faintness on suddenly assuming the erect from the recumbent position, dyspnæa, præcordial pain and oppression on exertion, and, it may be, anginoid pains are among those most frequently met with. The readiness with which they set in on slight exertion, and the degree of severity, must be taken into account in prognosis. When compensation is perfect, as may be the case in moderate lesions, they will not be much in evidence, but they are often the first danger signals in cases of old standing, premonitory of failing compensation.

Other points to be taken into consideration are:—
(1) The age of the patient at the time the lesion is established. This is of the utmost importance. If it occurs in youth, there is every chance of satisfactory compensation being established, but if it occurs in middle or later life, even as a result of acute endocarditis, there is little chance of the left ventricle responding to the call for the hypertrophy which is essential. The usual sequela in these cases and those of great severity in the young is extreme dilatation of the left ventricle, with secondary mitral incompetence, followed by complete failure of compensation and back working through the lungs. The right ventricle, being unequal to the demand upon it, breaks down,

and enlargement of the liver and dropsy, etc., ensues.
(2) The Murmur.—This may be loud or soft, long. or short. Sometimes it is inaudible at the aortic cartilage, but heard distinctly over the sternum to the left at the level of the third or fourth left costal cartilages. Speaking generally, a long, loud murmur indicates that the heart is acting vigorously, and that the leakage is not great, and is therefore of favourable prognostic significance. A weak, short murmur, replacing to a great extent the second sound, indicating the oppositestate of things, is necessarily of unfavourable augury.

(3) The Second Sound .- In moderate degrees of incompetence this is not replaced to any extent by the murmur. It is not always possible to be certain in listening over the aortic area that the second sound we hear there is not the pulmonic conducted across, but there can be no such doubt when we listen over the carotid in the neck. If the second sound is audible here, we can be sure that it is not replaced toany extent by the murmur, and it is therefore a

any extent by the murmur, and it is therefore a favourable element in prognosis.

The Aortic Incompetence of Later Life.—This is usually the result of chronic degenerative change, affecting not only the valves, but the aorta. Frequently dilatation of the root of the aorta, to which the valves are attached, is the primary lesion and the

main cause of the incompetence. The character of the aortic second sound in these cases is pathognomonic. It is, as a rule, low-pitched, loud and booming. This is quite distinct from simple accentuation, and is indi-cative of dilatation of the aorta. The diastolic murmur does not replace the sound to any extent, and may be inaudible at the aortic cartilage, but heard distinctly along the left border of the sternum at the level of the third or fourth aortal cartilage. The degree of incompetence is seldom very great, but is liable to be progressive from the nature of the changes in the aorta which have given rise to it. If at all severe, the left ventricle is, as a rule, unable to respond to the extra strain, and soon breaks down, with resulting secondary mitral incompetence, back working through the lungs, etc. The incompetence of the valves, however, may be the least serious of the danger with the strain. dangers which threaten the patient. In three instances I have seen aneurysm of the ascending aorta develop in cases which, when they first came under observation, presented only the physical signs of aortic incompetence and slight dilatation of the aorta. Degenerative changes in the heart wall, atheroma of the coronary arteries with resulting symptoms of angina, sclerosis of the renal vessels giving rise to uramic symptoms, are also possible sources of danger which we must bear in mind when we attempt to forecast the future in these cases.

AORTIC STENOSIS.

The effect of aortic stenosis is to diminish the size of the blood stream flowing from the heart into the aorta, and to throw extra work on the left ventricle, which has to use greater force to overcome the obstruction. Consequently the degree of hypertrophy of the left ventricle will be one of the most trustworthy indications of the degree of obstruction. As the calibre of the arteries is reduced in proportion to the size of the blood stream the size of the radial artery will be a further important clue to the degree of stenosis. These, being the two main guides as to the degree of severity of the lesion, are the two most important considerations in prognosis. They are also important in aviging of the degree of severity of the lesion, are the two most important in aviging of the degree of the second severity of the second s important in arriving at a diagnosis, as there are many varieties of systolic murmur heard at the aortic cartilage which do not indicate stenosis of the aortic orifice, and in later life a rough systolic murmur is frequently met with, due to some rigidity or degenerative changes in the aortic valves which do not cause actual stenosis. Time will not, however, permit of my discussing the differential diagnosis of these aortic systolic murmurs. Pure acrtic stenosis is not very common, and it is difficult to imagine how it can exist without some incompetence, but is more frequently met with in combination with aortic regurgitation, when the modification in the character of the pulse which it entails is of great diagnostic value. In my experience it is one of the least serious of the valvular lesions unless associated with degenerative changes in the aorta in later life. It is not progressive in the same degree as mitral stenosis, presumably because the unyielding wall of the aorta to which the valves are attached maintains its contour, and is not drawn in by the cicatricial contraction which affects the damaged valves. If, however, all three cusps of the

stenosis result. Aortic Stenosis and Incompetence Combined.—I think that there can be no question that when a moderate degree of stenosis supervenes on severe aortic incompetence the result is beneficial in so far as it diminishes the amount of reflux, and in more than one case of severe aortic incompetence I have seen this exemplified. The combined lesion, however, though limiting the amount of reflux, puts increased work on the left ventricle, and in some cases the stenosis progresses to such an unfavourable degree, as the result of cicatricial contraction of adherent cusps, that it becomes more serious than the original incompetence.

valve have been attacked by endocarditis, their edges may become adherent and an extreme degree of

MITRAL STENOSIS. The prognosis in this affection is always serious as regards duration of life, though the patient may survive a considerable number of years, as the tendency is for the constriction of the mitral orifice to be progressive. This is due in part to cicatricial contraction, but we must also recollect that in many cases the lesion is established early in life, before the growth of the heart is completed, and thus the relative disproportion between the mitral orifice and the cavities of the heart will increase as the heart attains its full development.

Another unfavourable element in prognosis is the high pressure in the pulmonary circulation. The main work of compensation falls on the right ventricle which hypertrophies in response to the demand. We have thus a powerful pump at one extremity with a narrow nozzle, the mitral orifice, at the distal end of a series of the consisting of the subgroup recode in which of tubes consisting of the pulmonary vessels, in which the pressure must necessarily be very greatly raised. As a consequence the unsupported capillaries become distended and tortuous, project into the alveoli, and frequently rupture. Proliferative changes take place in the alveolar walls, which become thickened, and tend to shrink and contract, and eventually we have the tough, firm condition of lung known as brown induration. The surface available for aeration of the blood is thus seriously impaired and diminished, which accounts for the dyspnoss and cyanosis which are such prominent features in advanced cases.

In attempting to arrive at a trustworthy prognosis in mitral stenosis we cannot rely to the same extent as in aortic disease on the structural changes in the heart as indicative of the severity of the lesion. The degree of hypertrophy of the right ventricle will afford useful information as to the extra work it is called on to do in the way of compensation, but the condition of the left ventricle is very variable. The tendency in simple mitral stenosis would be for the left ventricle to gradually diminish in size as the orifice narrows and the supply of blood becomes more limited, and in many cases post-mortem we find a very small left ventricle with a large hypertrophied right ventricle. often, however, the left ventricle is somewhat dilated and hypertrophied in spite of a marked degree of narrowing of the mitral orifice. The explanation of this would seem to be that considerable dilatation, due to myocarditis, together with mitral incompetence, was the primary lesion following on the attack of rheumatism; that some hypertrophy subsequently took place, and stenosis set in at a later period.

The size of the radial artery and pulse at the wrist affords important evidence as to the degree of stenosis, as it narrows down in proportion to the diminution in the supply of blood from the imperfectly filled left ventricle. Auscultatory evidence affords useful information as to the progress of the affection, as was first pointed out by my late father, who differentiated three stages thereby.

(1) The first stage, in which a presystolic murmur is heard leading up to a loud, short, first sound, followed by a second sound, which is frequently redupli-

(2) A second stage, in which the second sound is no longer heard at the apex, but only a presystolic murmur and first sound.

(3) A third stage, in which the presystolic murmur is lost, and only the first sound is audible.

In the first stage the symptoms are rarely of a serious nature. There may be some cyanosis, and dyspnæa may be readily induced if the stenosis is of old standing, in consequence of secondary changes in the lungs already referred to, but as a rule the symptoms are not severe enough to compel the patient to lie up unless bronchitis or some other complication supervenes. It will be noted on careful observation that the duration of systole is considerably shortened, the loud, snapping, first sound being rapidly followed by the reduplicated second, and that diastole is prolonged. This is only what we should expect, as it take a longer time than normal for the blood to flow from the auricle through the narrowed orifice to the ventricle, and it is probable that when systole com-mences the ventricle is imperfectly filled, and the systolic period will be shorter and less forcible in proportion to the diminished amount of work the ventricle has to perform.

In the second stage, I think we are justified in inferring that the second sound is no longer audible at the apex, because the diminished volume of blood pro-

pelled into the aorta at each systole is too small to pened into the aorta at each systole is too small to distend the aorta sufficiently to produce the powerful recoil which is necessary for the generation of an audible second sound. Consequently, if we accept this explanation, we may infer that the degree of stenosis is considerable, inasmuch as the ventricle is second to the proposition of the consequence of the consequen so imperfectly filled, and that the prognosis is proportionately more unfavourable.

In the third stage the disappearance of the pre-systolic murmur indicates the breakdown of compen-sation. The rhythm is extremely irregular, and frequently we hear a confusing medley of sounds on listening at the apex—sometimes a first sound, sometimes a systolic murmur, sometimes both. The explanation appears to be that the right ventricle having given out, there is insufficient pressure in the left auricle to generate a presystolic murmur; this accounts for its disappearance. When the pressure in the auricle is sufficient to prevent reflux from the ventricle we have a first sound only; when the pressure in the auricle is so low that it does not prevent reflux we have a systolic mumur. The pressure in the left auricle varying greatly according to the force and frequency of the beats of the right ventricle, and being also influenced by respiration, we thus have this confusing medley of sounds. We are apt to forget that in mitral stenosis there are frequently no valves, but simply a slit, or circular hole, in a diaphragm of fibrous tissue between the auricle and ventricle, and that in all cases we should have mitral reflux were it not prevented by the high pressure in the auricle maintained by the hypertrophied right ventricle. The occurrence, therefore, of mitral reflux when the right ventricle breaks down, in cases where it has not been present for many years, is readily understandable. Of course, apart from this, mitral incompetence is very frequently met with combined stenosis, and I am inclined to think that this combination is more favourable than stenosis alone as indicating that the orifice is not greatly contracted. the auricle and ventricle, and that in all cases we indicating that the orifice is not greatly contracted, and that it may in some instances represent an earlier stage of what eventually develops into pure mitral stenosis when the orifice becomes too small to allow of regurgitation.

The symptoms are, perhaps, some of the most important factors in prognosis. Cyanosis and dyspnosa on slight exertion are especially liable to be present, and the degree of ease with which they are induced effords useful evidence as to the baneful effect the high pressure in the pulmonary circulation is having

Infarction of the lungs is frequently met with in the terminal stages of mitral stenosis, and is of grave prognostic significance, as it indicates extreme stasis of the pulmonary circulation. In my opinion it is due to thrombosis from stagnation of the circulation rather than to embolism, and I have never known a case recover efficient compensation after its occurrence. Dropsy of the lower limbs is a very late symptom, and may be absent throughout, though symptom, and may be absent throughout, though ascites is not infrequently met with, whereas in mitral incompetence dropsy is common, and may occur comparatively early in the course of the disease, and efficient compensation may be restored even after the course of the disease, and efficient compensation may be restored even after the course of the co several attacks. In pure mitral stenosis, if present at all, it is usually a terminal feature occurring only in the third stage.

MITRAL INCOMPETENCE.

The range of possibilities as regards prognosis is greater in mitral incompetence than in any other valvular affection. It may be due to a variety of causes, such as dilatation of the left ventricle without any lesion of the valves, as may occur after various acute febrile infections, more especially when the patient returns to work too soon after illness. I have frequently met with it in out-patients recovering from influenza or suffering from acute pulmonary tuber-culosis. It is often present in anæmia, and is met with in Bright's disease, more especially the sub-acute varieties attended with cedema. I do not propose to varieties attended with cedema. I do not propose to discuss the prognosis of these varieties, as it does not fall within the scope of my paper, but I only instance them so that we shall not forget that mitral incompetence may be present without any lesion of the valves, and to support my contention that the latter is not per se necessarily at all a serious affection.

When, as a sequela to an attack of rheumatism in a child, we find the left ventricle greatly enlarged, with a considerable degree of dilatation and slight hypertrophy, and note that there are marked symptoms, such as rapid respiration, dyspnæa on slight exertion, and that a loud blowing systolic murmur is present at the apex, we are, perhaps, too inclined to attribute these to a lesion of the mitral valves. In many cases of this nature, in which enlargement of the liver, dropsy, etc., have set in, and which have eventually proved fatal, I have found at the autopsy no actual lesion of the mitral valves, but only extreme dilatation of the ventricle. This condition is more commonly met with in cases of pericarditis, but may be present also in the absence of this complication. There can be no question here that the fatal issue is the result, not of the valvular lesion, but of the damage to the myocardium inflicted by the toxins of the rheumatic micro-organisms and consequent loss of tone of the muscle, which gives rise to extreme dilatation of the ventricle. Microscopically we see evidence of this damage in the loss of striation, and the granular and fatty degeneration of the muscle fibres, and the areas of cell infiltration scattered throughout. When, therefore, we have mitral incompetence associated with great dilatation of the left ventricle, which does not subside after the attack of rheumatism, the prognosis is necessarily grave. The mere existence of mitral incompetence counct well give rise to dilatation of the left ventricle, but in cases in which compensatory changes in the right ventricle have taken place, we may find the aper beat displaced outwards and slightly downwards by the hypertrophy of the right ventricle.

If a mitral systolic murmur be established during an attack of rheumatism, and there is no marked dilatation of the left ventricle, we may infer that the incompetence is the result of a lesion to the valves by endocarditis, and not attributable to the myocarditis, and we must endeavour to estimate its severity in order to arrive at a trustworthy prognosis. degree to which the murmur replaces the first sound, the character of the pulse, and the readiness with which symptoms are induced, will be our best guide as to the extent of the lesion, and consequently as to prognosis. If a good first sound is audible as well as the murmur, the lesion is rarely so severe as to produce symptoms in the nature of back working, and it is probable that efficient compensation will be readily established under favourable circumstances. It is remarkable in out-patient work what a number of cases of mitral incompetence one comes across in patients who are not aware that they have any cardiac lesion, as compensation is so efficient, and in whom the lesion appears to date from an attack of rheumatism many years ago, if, indeed, they are aware that they have had rheumatism; for in childhood the articular manifestations are often so slight that the patient is not compelled to lay up, and the presence of a cardiac lesion is not even suspected. If the systolic murmur replaces entirely, or greatly modifies the first sound, we may infer that the lesion is severe, inasmuch as the intraventricular pressure is so reduced by the regurgitation through the mitral orifice that it is insufficient to make the muscular wall of the ventricle, as it suddenly contracts down, taut enough to generate a first sound. Consequently, we shall not expect efficient compensation, and slight exertion will be liable to produce symptoms.

One of the dangers to be apprehended in the future in cases of mitral incompetence, which should make our prognosis guarded even in apparently favourable cases, is the possibility of the onset of mitral stenosis, and my impression is that in many cases the patient who has had mitral incompetence for some years, it may be, only comes up for medical advice when mitral stenosis has set in, and symptoms attributable

to that affection compel his attention.

COUNCIL schools at Needham Market have been closed because of an outbreak of diphtheria, and the British schools at Bishops Stortford because of an epidemic of measles. Nearly 200 cases of measles have occurred in the Ilford elementary schools.

# **OUT-PATIENT'S ROOM.**

GUY'S HOSPITAL.

Demonstration upon a Swelling in the Loin, By R. P. ROWLANDS, M.S., F.R.C.S.

This man, who is only 25 years of age, seems to be healthy except for the prominent swelling which you see on the right side of the loin posteriorly. This has been growing for about three or four months, and has rapidly increased in size during the last week. It has caused a little aching pain on the right side of the back, but the patient has been able to do his daily work up to the present time.

There is no history of pneumonia, pleurisy, or any

Inere is no history of pneumonia, pleurisy, or any symptoms suggestive of disease of the right kidney. There is no evidence of phthisis. You will notice that the swelling is strictly limited to the right side of the back in the lumbar region. It is as large as half a cocoanut, and the greater part of it is situated over the space between the last rib, the outer border of the erector spinæ and the crest of ilium. Its surface is smooth and its outline nearly hamispherical thus smooth, and its outline nearly hemispherical, thus suggesting a collection of fluid or a lipoma. The skin is a little inflamed and adherent partly as a result of counter-irritation; it does not crinkle over the swelling. Fluctuation can be easily made out from above down as well as from side to side. Thus lipoma is excluded. Remember that false fluctuation can be excluded. obtained in a lipoma, and also from side to side of the erector spinæ.

The swelling is dull on percussion, and therefore does not contain gas. Although prominent and superficial, it is not translucent, therefore it does not contain clear liquid. There is no history of an injury, and the onset has been gradual, therefore it is not a

hæmatoma.

The gradual onset and the absence of pyrexia and the local signs of acute inflammation exclude acute abscess. The swelling is, therefore, a chronic abscess.

The swelling is, therefore, a chronic assess. It remains to prove its probable origin.

This is not likely to be spinal caries, for the following reasons:—The mobility of the lumbo-dorsal spine is not impaired; pressure upon the spinous processes and upon the head and shoulders fails to elicit any sign of tenderness. Moreover, fluctuation cannot be obtained through the loin from below the costal margin in front or from the region of the psoas or iliacus muscles. The absence of fluctuation upon binancel examination also serves to exclude all varieties. manual examination also serves to exclude all varieties of perinephritic abscess. Moreover, the absence of pyuria, renal pain, and frequency of micturition help to exclude renal disease. I have known a subacute subphrenic abscess of pneumococcal origin give rise to some difficulty in diagnosis. The patient before you is by no means ill enough to suggest a subphrenic abscess. Moreover, there is usually fluctuation upon bimanual examination through the loin when the

abscess is large enough to project below the ribs.

If you look carefully you will notice a small, deep, upward prolongation of the flaccid swelling, and that you can distend this recess by pressing upon the main abscess. You will also notice that there is an impulse on coughing, and that the fluid from the recess can be reduced into the chest through the eleventh intercostal space. It is, therefore, more than probable that the abscess started within the chest, above the diaphragm and below the pleural reflexion. You notice that there is a little dulness at the extreme lower end of the right side of the chest posteriorly; but the air entry good, and there are no indications of empyema in the history or in the physical signs. The old abscess is, therefore, almost certainly due to caries on the inner aspect of the 11th or 12th rib. No thickening of either of these can be made out, but they are tender on pressure. You may remember that tuberculous caries very frequently starts upon the deep surface of the ribs, and that it may affect this surface only. In the "Guy's Hospital Reports for 1907" I drew special attention to this fact, and published drawings of ribs which I had removed, and which illustrated this important fact. The patient from whom one of these specimens

had been removed had had an intermittent discharge over the liver for 20 years, in spite of many scraping operations, and had been supposed at last to be suffering from subdiaphragmatic abscess. For successful treatment it is necessary to explore thoroughly and to remove all that part of the rib which is found to be diseased. Nothing less than this affords permanent diseased. This patient is coming into the hospital for such a radical operation. It is well to remember, however, that, as in most examples of surgical tuberculosis, which are apparently local, there is almost certainly a hidden infecting focus, perhaps in the form of chronic phthisis, or tuberculous mesenteric, or mediastinal glands. When this significant fact is borne in mind, it makes us especially careful of the prognosis in these cases of caries of the ribs in which the infection is from the contiguous pleura in many cases. For this reason, also, after-treatment by injections of tuberculin may be wise.

# OPERATING THEATRES.

ST. THOMAS'S HOSPITAL.

FIBROMYOMA OF THE APPENDIX.—REMARKS ABOUT THE METHOD OF REMOVING THE APPENDIX.—MR. CORNER said that the patient was a young man, æt. 23, who had had two attacks of appendicitis, and was sent by his doctor to have his appendix removed. The details of his first attack were meagre, and he was only incapacitated for a few days. In order to understand what is happening in a case of appendicitis, Mr. Corner pointed out, it is important to find some relation between the clinical history, which can be ascertained, and the condition of the appendix, which can only be discovered at operation or autopsy. But the surgeon must try to learn from the clinical history what is going on inside, so as to advise the patient. This case offers a good opportunity to try and find some such relationship, because the patient has a peculiar and striking clinical history. Whilst patient. has a peculiar and striking clinical history. walking down the street in his usual health, he was suddenly seized with abdominal pain, which was so severe as to make him fall down, and necessitate his severe as to make him fall down, and necessitate his removal in a cab. After this he was in bed for seven weeks, during the first three of which he had great abdominal pain. There was little fever, and no sickness. Such a history is so unusual in appendicitis that it would seem that there must be some unusual condition present to explain why it occurred.

In commenting on the operation, Mr. Corner said that it is begun by incising the skin and fat over the right rectus muscle for three or four inches, parallel with its fibres, and half an inch internal to the semi-lunar line. The anterior sheath of the rectus is exposed and incised the length of the wound. exposed and incised the length of the wound. Iwo pairs of artery forceps are placed on the outer lip of the incision in the rectus sheath, which is freed until the outer margin is reached. If a tendinous intersection is present in the rectus muscle, the knife will be the property of the control of the con be required to do this, and at least one vessel will bleed from the cut intersection. The rectus muscle is now withdrawn inwards with two retractors, one in the upper and one in the lower part of the wound, thus exposing the posterior rectus sheath. The nerves to the rectus will be seen running obliquely across the posterior rectus sheath in such a way that they must be divided if a longitudinal incision is made in it. In consequence, an oblique incision, parallel with the nerves, is made through the posterior rectus sheath and peritoneum. The forefinger is now introduced into the abdomen. The most frequent mistake at this stage of the operation is to put the finger straight into the abdomen when it enters the pelvis amongst the small intestines. The proper way to find the cæcum is to feel the brim of the pelvis, and then pass the finger outwards across the iliac fossa, when pass the finger outwards across the iliac fossa, when it must encounter the cæcum where it is attached to the posterior abdominal wall. The cæcum is hooked by the finger and delivered on to the surface of the abdomen. The anterior longitudinal band is followed downwards to the root of the appendix. If adhesions are felt round the appendix, it is advisable to insets some gauze plugs around, as some pus may be enclosed in the adhesions. After delivering the appendix, which in the present case had a number of adhesions, it is clamped, close to the cæcum, with an appendix clamp. The mesentery of the appendix is now secured with two artery forceps and ligature. Whilst this is being done the heavy clamp on the appendix has crushed and divided the mucous membrane and muscular layers, leaving only the peritoneal coats to be tigatured when the clamp is removed. In this way sepsis is avoided in removing the appendix, as it is ligatured with silk at the proximal part of the crushed area, seized with artery forceps just above it to prevent anything within the appendix running out as it is divided at the upper margin of the crushed area. By this method the drop of pure carbolic to sterilise the stump can be dispensed with. The wound is then closed in layers. After sewing the incision in the posterior rectus sheath and the peritoneum, the retracted rectus muscle is allowed to slip back into its proper position and cover the line of sutures. When this is all that has been done to repair the abdominal wall, he had several times seen patients strain or vomit in the course of the operation, and there has been no vestige of a hernial protrusion, showing the very great value of this method for preventing post-operative herniæ. The anterior rectus sheath is then sutured over the muscle, and the skin wound closed.

After the operation Mr. Corner examined the ablated

After the operation Mr. Corner examined the ablated appendix, and found in its distal end a small, rounded submucous tumour, which, having a definite capsule, was of the non-malignant variety. Such innocent tumours of the appendix, he said, were very rare, and practically only fibromyomata had been described. These were found most frequently in connection with uterine fibroids. The presence of this small tumour, he thought, suggested a possible explanation for the fact that the attack began so suddenly as to make the man fall down in the street. Such acute attacks are generally sudden strangulations, perforations, or colic. This patient had no strangulation or perforation. But if the little tumour became intussuscepted into the appendix, he would have very sharp and sudden pain. The length of his illness is also explained by the spontaneous reduction of this little intussusception. Hence this patient may have presented a combination of two unusual conditions—a simple tumour of the appendix and an intussusception of the appendix.

Microscopically, the tumour was a fibromyoma.

THE ROYAL SOCIETY OF MEDICINE.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION.

MEETING HELD THURSDAY, MARCH 12TH, 1909.

The President, Dr. HERBERT R. SPENCER, in the Chair.

Dr. Drummond Maxwell read the clinical account of a

The case occurred in a primigravida, æt. 26. The chief features of interest in the case lay in the difficulty of diagnosis, since the patient, after admission to hospital, ceased vomiting, and there was only the history of severe vomiting at home, unassociated, however, with marked wasting. The toxic nature of the case did not reveal itself in any characteristic alteration of the urine; there was no albuminuria; the only ominous signs on admission were drowsiness and a very rapid, weak pulse; there was no jaundice. Patient passed successively through stages of restlessness, delirium, mania, and final coma. Autopsy revealed hyaline degeneration and necrosis of the central cells of the hepatic lobules, the kidneys also showing a severe parenchymatous nephritis; sections of both tissues were shown under the microscope. The diagnosis of this distinctly atypical case was uncertain during life, and was based finally on the pathological investigation pest-mortem.

A short communication was read on a case of PRIMARY OVARIAN ACTINOMYCOSIS,

by Dr. Frank E. Taylor and Welby E. Fisher, F.R.C.S. The authors pointed out that actinomycosis of the ovary constitutes one of the curiosities of gynæcology, only six cases of this condition being on record. In none of these had the ovary been the primary seat of infection, but had been infected by extension of the disease originating either in the intestines or in the vagina, uterus, or Fallopian tubes.

The authors claim that in their case the ovary was the primary seat of the disease. The patient was a cook, æt. 34, and single, and was admitted into the Chelsea Hospital for Women in June, 1908, complaining of abdominal pain. The periods were very irregular, and very profuse. Pain was first noticed 3½ years before, and soon after she became troubled with night sweats, which had continued up to admission. About this time she was seen by Dr. Fenton, who found the right ovary enlarged. The patient declined operation at this time. Pain and discomfort continued intermittently, and at one time she passed blood and pus in the urine. Marked anæmia and loss of flesh finally led the patient to enter the hospital. She was then found to have a tumour the size of a child's head, which filled the pelvis. There was no tenderness, but the tumour was fixed. The temperature was raised. The tumour was removed, when it was found to be very adherent to the surrounding parts. Both Fallopian tubes were occluded, and bilateral salpingo-cophorectomy was performed. The patient for a time was very ill, but she ultimately recovered, and left the hospital with a small sinus. Shortly after a large abscess burst, and a large amount of pus escaped through the sinus. The patient at the present time is fairly well, with hardly any discharge. The microscopical examination showed masses of streptothrix.

Professor R. F. C. LEITH said that the specimen shown was a good example of ovarian actinomycosis, caused by the streptothrix actinomyces, but caution must be exercised before accepting the contention of the authors that the disease was primary in the ovary. Of the recorded cases of actinomycosis involving the ovary, a not inconsiderable number, there were some in which the evidence favouring a primary incidence of the disease in the ovary was very strong, sufficiently so to convince their observers of their authenticity. In the case under consideration, the clinical history, both before and since the operation, lent considerable support to the authors' contentions, but the actual relationships of the ovary to all the neighbouring tissues were not fully revealed. Professor Leith referred to a case investigated by him in which the ovary and part of the tube were affected. The rectal was thickened, and in the dense fibrous adhesions binding it to the ovary there were plentiful actinomyces growth. Colonies were also found in the rectal myces growth. Colonies were also found in the recusion wall and in the wall of the descending colon. His interpretation of this case, though still sub judice, placed the primary disease in the intestine, from which it had spread to the ovary, the intestinal lesions subsequently cicatrising and healing. He ventured to suggest that a similar interpretation might be placed upon the present case. The speculation of the authors that the actinomyces had entered the body by some hidden path without causing a local lesion, and had been carried to the ovary by the blood stream, was scarcely probable. One of the chief characteristics of this disease was the formation of a local lesion at or near the site of entrance, and a spread therefrom by direct continuity of tissue. Spread by the blood stream did take place, particularly the portal blood stream, but this was characteristically a late method

Dr. W. S. A. GRIFFITH referred to a case of actinomycosis affecting the generative organs in a women which had occurred in his practice. The nature of the disease was not suspected until late in the illness. The patient died from exhaustion.

of extension.

Dr. T. G. WILSON remarked how difficult it was to be quite sure that a condition like actinomycosis was really primary in the ovary, but had not come originally from some part of the bowel. Illustrating

this point, he mentioned a case of actinomycosis he had seen, when the vermiform appendix was adherent to a right-sided ovarian mass containing pultaceous material, and that subsequently to operation the presence of actinomycosis was demonstrated in both the appendix and in the ovarian mass. In this case the opinion was arrived at that the condition was certainly a primary infection of the bowel, which had spread to the ovary via the adherent appendix.

Dr. Hy. Russell Andrews read notes of a case of PRIMARY CARCINOMA OF THE VAGINA, in which the uterus and the whole of the vagina were removed. The patient, a multipara, æt. 62, had a carcinomatous ulcer, the size of a two-shilling-piece, high up on the posterior vaginal wall. The cervix was free from carcinoma. The whole vagina was dissected out from below, and removed together with the uterus. At an early stage of the operation the vagina uterus. At an early stage of the operation the vagina was converted into a closed bag by clamping with forceps bent at a right angle, with the object of preventing infection of the raw surfaces by carcinoma cells. The peritoneal cavity was closed by sutures, and the cavity between the rectum and urethra became obliterated. The patient was quite well when last seen, February, 1909, eighteen months after the operation. operation.

The President had operated by Wertheim's method on a case of primary cancer of the vagina, and although the patient recovered, she died within about a year of recurrence. He thought there was some advantage in the operation performed by Dr. Andrews, especially as there would appear to be less risk of the vagina tearing: this was very liable to occur in primary cancer of the vagina owing to the thinness and friability, and occurred in his case. He had seen at least three other cases of cancer of the vagina, which these cases appeared to be very great, but Wertheim had had some cases of prolonged freedom from recurrence after the extended abdominal operation.

Dr. F. J. McCann said he had operated on a

patient with primary cancer of the vagina by a method which had not been mentioned by the author of the paper. A wide transverse incision was made through the anterior vaginal wall. The bladder and ureters were separated and the utero-vesical pouch opened. The were separated and the utero-vesical pouch opened. The fundus and body of the uterus were rolled out by slow, gentle traction with volsellum. The broad ligaments were ligatured from above downwards. The posterior vaginal wall was next divided on either side, and the uterus and posterior vaginal wall pulled further outwards. The posterior vaginal was then divided transversely well below the growth from the peritoneal aspect, and was removed along with the uterus in one piece. This patient was free from recurrence when less seen at years after the operation. Dr. McCann last seen 44 years after the operation. Dr. McCann had seen five examples of primary cancer of the Dr. McCann vagina.

Dr. H. MACNAUGHTON-JONES referred to a case of primary carcinoma of the vagina which he had brought before the British Gynæcological Society in May, 1907. Seeing the very few cases of primary car-cinoma of the vagina recorded in British literature, he had sought for some statistics from abroad. From all these sources he had only been able to collect 23 instances of primary disease. The interesting point in his—Dr. Macnaughton-Jones'—case was that it in his—Dr. Macnaughton-Jones'—case was that it exemplified the two types of disease as described by Roger Williams—the tubular, or more chronic form, with actively proliferating columnar epithelium, and the nodular or squamous type, occurring in nests, in which the dissemination occurred more widely and spread more rapidly. George Noble, of Atlanta, had referred to the frequency with which primary carcinoma originated in the region of the urethra, as well as in the posterior wall. All authorities were agreed as to the disheartening results of operation, even the most radical measures being usually unsuccessful in preventing recurrence. In deciding the point of primary infection, it was absolutely necessary to exclude the portio and vulva.

Dr. A. H. N. Lewers said he was surprised to find

some of those present considered this condition very rare. He had himself seen, speaking from memory, at least fifteen or twenty cases of primary carcinoma

of the vagina. In none of them, however, was the disease at a sufficiently early stage to induce him to attempt a radical operation, and he had therefore been obliged merely to scrape and cauterise the growth in such as had seemed to require some active treatment.

Dr. RUSSELL ANDREWS, in reply, said that this was the only case of primary carcinoma of the vagina that he had seen. From what he had read he had considered that the condition was rare. He was surprised that some of the speakers considered that primary carcinoma of the vagina was fairly common. Dr. Macnaughton-Jones had shown that it was rarely seen on the Continent.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

MEETING HELD FRIDAY, MARCH 12TH, 1909.

The President, Dr. A. R. Parsons, in the Chair.

#### BRONCHIECTASIS.

Dr. JAMES LITTLE exhibited a specimen of bronchiectasis from a man, æt. 25, a car driver, who thought he had caught cold when driving a party to the International football match. He remained at home a fortnight, and then became so ill that he was brought to hospital. He was extremely short of breath and Later he became breathless to the last degree, and had the peculiar hue which Dr. Hudson used tosay was a fatal hue in heart disease—a mixture of unaerated blood and jaundice. He lived three days afterwards. His temperature was never elevated, and his pulse was always feeble. Six years previously, when in hospital with scarlatina, it had been noticed that his heart was beating considerably to the right. When he examined him he found the sounds over the back of the right chest were those of large cavities in the lungs. Over the lower lobe of the left lung there was dulness on percussion. At the post-mortem the heart was found dragged to the right side by pleural adhesions. Pneumococci were found in the pleural adhesions. Pneumococci were found in the sputum during life. The lower lobe of the left lung was extremely congested, and the cause of death appeared to be pneumonia. The right lung presented immensely dilated bronchial tubes in every part. The auriculo-ventricular orifices of the heart were much dilated. The left ventricle was considerably dilated and hypertrophied. The right ventricle was extremely dilated and somewhat hypertrophied. The patient brought up a large quantity of purulent spit, but it was not offensive in smell, which was very strange, as he could hardly conceive a lung less able to expel sputum before it decomposed.

Sir John Moore said that if the bronchial tubes were dilated throughout the entire length there was less likelihood for putrefaction and consequent foctor to occur than if dilated through only a portion of their extent. The condition of the left base looked like collateral hyperæmia rather than pneumonia, as the

temperature was not high.

CEREBRAL TUMOUR. Dr. Coleman exhibited a brain tumour from a girl, æt. 25. For about six months previous to her admission to hospital last month she had suffered from persistent headache, and for the last three or four from occasional vomiting. On examination she had paralysis of the right external rectus, and double optic neuritis. To relieve the headache and pressure he performed lumbar puncture, and removed, under considerable pressure, 19 cc. of practically normal fluid. She died a week afterwards of gradually progressing dulness passing into coma. At the postmortem a large tumour was found involving the right frontal lobe of the brain. It was distinctly circumscribed, and could easily shell out of the brain substance. Microscopically it was a sarcoma. There were no localising symptoms.

The PRESIDENT recalled a similar case in which there was no paralysis, but a marked alteration in the mental condition of the patient. Before he died he developed paralysis on one side of his body.

Mr. Wheeler said the specimen was encouraging to the surgeon, as there was no doubt the tumour could be successfully removed if it could be diagnosed.

POLYSEROSITIS.

Mr. W. I. DE C. WHEELER exhibited organs from a Mr. W. I. DE C. WHEELER exhibited organs from a case of polyserositis. The patient, a man, æt. 34, had been sent from Galway, with a large ascites. He was fairly healthy and had no other symptoms. Two years previously he had had his right pleura tapped, and when he came to hospital a small left pleural effusion was found and tapped. The ascites increased in hospital. Ten days after admission the abdomen was opened. Covering the liver there was a thick capsule, and over it there were little dips as if peas had been pressed into the surface of it. The liver was not cirrhosed. There were adhesions between the great omentum and the abdominal wall. The Talma-Morrison operation was performed. No signs of tubercle were found, and there was no growth of any kind. The operation seemed to relieve the ascites, and he lived eight weeks. He was only tapped once after it, and a very small quantity of fluid was

Dr. HARVEY said that on opening the abdomen only a small quantity of fluid was seen, but a considerable amount was afterwards found shut off by intestinal adhesions. The peritoneum covering the intestines was everywhere thickened, and in places an abundance of comparatively recent fibrin was matting the coils together. The liver was covered with a thick, opaque white capsule, in which irregular pits were seen, giving somewhat the appearance presented by snow on which drops of water is sprinkled. The surface of the spleen was somewhat similar. The cut surface of these organs was scarcely, if at all, abnormal. The spleen was perhaps a little tough, but not at all markedly cirrbotic. The kidneys were normal in macroscopic appearance; their capsules stripped easily. The thoracic viscera were densely adherent to themselves and to the parietes. It was found possible after some time to isolate the left lung which, in addition to general adhesions, was firmly attached to the diaphragm by a dense finger-like process. The pleura was enormously thickened, and the whole organ when removed looked rather like an enlarged spleen. It was not possible to separate the heart and peri-cardium from the right lung. The pleura was not so extremely dense as that on the left side, and the right pleural cavity contained a considerable amount of fluid. The pericardium was greatly thickened and closely adherent everywhere to the heart. On section it had a dense cartilaginous appearance. The heart it had a dense cartilaginous appearance. was somewhat atrophic, the endocardium normal. In-oculations were made from the centrifuged fluid in the pleural and peritoneal sacs into four guinea pigs, but without result. Microscopic sections show the organs to be remarkably free from cirrhosis except immediately beneath the thickened capsules. These latter are formed of a dense connective tissue which has undergone hyaline change. The organs themselves are fairly normal, but for congestion and some parenchymatous degeneration to be seen in the liver and kidneys. Part of the left lung near the pleural surface shows collapse with fibrosis, while portions of the right lung are emphysematous. To sum up, the organs, with the exception of the above-mentioned changes, were healthy, while their serous coverings were im-mensely thickened, and such serous cavities of the body as were not totally obliterated were distended with fluid. There was absolutely no evidence of tuber-culosis either in the sections or as a result of inocu-

Dr. KILPATRICK said he had seen the patient during life, and was very much of the opinion that the multiple serous effusions were probably the result of tubercular infection. He saw him after the operation, and he was perfectly comfortable and better. Then he suddenly died. Both the pathological finding and the clinical history were very remarkable.

Dr. MOORHEAD said he had seen an almost

identical case two and a balf years ago. Such cases were of very considerable interest from their rarity. Mr. Wheeler, in reply, said it had occurred to him that tertiary syphilis might explain the case, but there was no history of such.

Dr. HARVEY, in reply, said the remarkable thing was not why the man died, but how on earth he lived. He had seen nothing so dense as the mass of adhesions in his thorax, and it was wonderful how the organs could move at all.

ORGANS FROM (a) PHARYNGEAL DIPHTHERIA.

(b) CASR OF HEART DISEASE.

Dr. O'CARROLL exhibited a pharynx from a child who had suddenly died, convalescent from pharyngeal diphtheria. He also exhibited specimens from a woman, æt. 46, who came to hospital apparently in the last æt. 40, who came to mospital apparatus, ... stage of heart disease, with dropsy, and some degree of cyanosis. She sank after about ten days. diagnosis was mitral regurgitation, although there was no distinct murmur.

Dr. EARL said that in the first specimen there was a deep ulcer into the tonsil, and the membrane extended down to the base of the larynx. In the other specimens the heart showed general hypertrophy of all the chambers, with some dilatation. Both mitral and tricuspid orifices were abnormally large. The valves were healthy. The aorta was much dilated and atheromatous. The right kidney contained an enormous infarction. The other kidney was a very small organ, and contained calculi. The capsule was very adherent, and there was practically no cortex. A myoma was found in the uterus, also an ordinary mucous polypus, and another on the wall. The other organs were

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

MEETING HELD AT SHEFFIELD ON MARCH 19TH, 1909.

The President, Dr. J. W. MARTIN (Sheffield), in the Chair.

A vote of condolence to the family of the late Dr. J. H. Keeling, an original member of the Society, was proposed by Dr. LLOYD ROBERTS, seconded by Mr. R. FAVELL, supported by the PRESIDENT, and carried.

Mr. R. FAVELL (Sheffield) showed a specimen of

hydrosalpinx.
Dr. A. J. Wallace (Liverpol) showed a glass vaginal nozzle, which he had removed from the bladder by the vaginal route. The nozzle was 5\frac{3}{2} inches in length and \frac{3}{2} inch in diameter. It had slipped into the bladder, seven weeks previously, during the process of vulval douching, by a nurse, of a recently confined woman.

Mr. ARTHUR CONNELL (Sheffield) described a case, and showed the specimen, of
COMPLETE TORSION OF THE INTERNAL GENITALIA WITH A

LARGE INTERSTITIAL FIBROID.

The patient, a spinster of 50, had suffered, on several occasions during the previous five weeks, from subacute attacks of abdominal pain and vomiting, which had always commenced during defæcation. Her medical attendant had found an abdominal tumour of about the size of a six months' pregnant uterus. The last attack was the most severe, and had lasted three days when Mr. Connell first saw her. She was then desperately ill. He diagnosed a fibroid with torsion of its pedicle, and advised immediate operation. The uterus and its appendages were rapidly removed, after a preliminary enucleation of the large interstitial myoma. The uterine and ovarian vessels were thrombosed and did not require ligaturing. The patient made a good recovery, though a transient hemiplegia commenced on the day after operation. The cavity of the uterus was distended with blood clot, and the uterus with its appendages and the tumour were in a state of infarction. Mr. Connell also showed a portion of the pelvic colon successfully resected on account of its dense adhesion to a pyosalpinx.

Dr. A. CUFF (Sheffield) showed the macroscopical

and microscopical specimens from a case of bilateral, malignant, papillary cysto-adenoma of the overies. There was considerable ascites, and the peritoneum was studded with papillary growths. Three months later there were no signs of recurrence.

Dr. LLOYD ROBERTS (Manchester) read the notes and showed the specimen of a case of carcinoma of the corpus uteri, successfully removed, per vaginam, from

a multipara, æt. 58.
Dr. J. E. Gemmell (Liverpool) read a short paper on

FIBROMYOMA UTERI AS A CAUSE OF PURPPERAL TOXAMIA.

He related three cases which illustrated different
methods of puerperal infection dependent upon such growths: (1) Strangulation of the pedicle leading to sloughing and general septic peritonitis; (2) toxemic from necrosis of the growth itself; (3) sapræmic infection from the placental site together with necrosis of the growth. The first two cases were successfully treated by subtotal hysterectomy. In the third case a sloughing, submucous fibroid was removed piecemeal, per vaginam, on the sixth day of the puerperium. Immediate improvement followed, but death, from pulmonary embolism, occurred a few days later. He advocated, in the absence of symptoms of toxæmia, that the tumour should be left until involution is completed and then dealt with by any operative method which is deemed most suitable, but when toxæmia arises, from any cause whatever, complete or subtotal hysterectomy is the operation of choice and the safest.

# CORRESPONDENCE.

# FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, March 28th, 1909.
GRIPPE AND ITS TREATMENT.

GRIPPE, or influenza, is one of the commonest affections, returning each winter to afflict humanity; and yet, although so well known, few diseases have given rise to so much difference of opinion and engendered so many opposing theories. Broussais simply denied its existence: for him, grippe was an imaginary affection created by doctors in quest of new patients!

At the Académie de Médecine grippe was the subject of numerous discussions, and the cross-fire of ideas put forward rendered it difficult to form a rational popular.

opinion.

Some years ago influenza was considered a benign affection requiring only a few days' rest by the fire side. Yet four epidemics of the malady were observed in the last century: those of 1830, 1836, 1848, and 1889. The last came from the extreme East. It began at Bokhara in May, attained Moscow in September, St. Petersburg in October; towards the middle of November Berlin was infected, then Paris and London. In one year it encircled the globe.

A malady is at first diagnosed by the symptoms that appeal to our senses. Pathological anatomy can, in certain cases, furnish its contribution to confirm the diagnosis, but in grippe this latter means is wanting.

The cause alone and the discovery of the exciting agent (microbe) could furnish a decisive argument. It was thus that on all sides efforts were made to isolate the microbe. In 1902 Pfeiffer described a bacillus that everyone thought to be specific. It was found in Russia in the waters of the rivers, and it was said that its presence was constant in the expectoration of the patients. But this discovery was found to be inexact, for in 1905 Besançon made a communication before the Hospital Society in which he showed that in 25 patients examined the bacillus of Pfeiffer could not be found.

Kietz and Stemberg made similar observations at Vienna a few weeks later: they found but pneumococci and certain kinds of saprophytes. speaking, influenza increases in gravity in passing successively through organisms as explained by its greater malignity in the present day as compared with the

The influence of our social living, says M. Besançon, made up of mental and physical strain with

cerebral fatigue might be invoked. The more we live, the more the malady seems to localise itself in the nerve centres, as proved by the epidemics of cerebrospinal meningitis following grippe, observed in Germany and in certain regiments in France, and also in some scattered regions.

Grippe may present itself in one of three forms, or

the three forms may coincide: Respiratory grippe; nervous form; gastro-intestinal form.

In pulmonary grippe, says M. Le Cendre, the inva-sion is generally brusque, the cough incessant and wearisome; the larynx is inflamed, and the lungs are rapidly affected; souffles and rales of a special viscous character are observed over the lungs, while nervous phenomena predominate, with paralysis of the vaso-motor system, resulting in intense and persistent vaso-dilatation; the dilated vessels seem paralysed, while the muscles of Reissessen have lost a great part of their elasticity.

In the nervous form, the patients are considerably agitated and complain of lancinating pains in different regions, resembling seizures of neuralgia.

The gastro-intestinal form is characterised by violent and frequent vomiting, with profuse diarrhœa, while

the tongue has a peculiar opaline aspect.

Complications of grippe are as numerous as they are grave. In the first place, grippe is a frequent exciting cause of tuberculosis of the lungs; nephritits is often observed, while inflammation of the liver has been noticed more than once. Meunier observed four cases of septicæmia, and many authors have incriminated grippe as one of the causes of appendicitis. Other affections as peritonitis, otitis, tonsillitis, etc., have been sometimes proved to be in intimate relation with grippe. But one point should not be overlooked, and that is, that an attack of grippe can be followed by a second attack much graver than the first, which had yielded to appropriate treatment. A patient pressed to return to his business, resumes his usual mode of living, and a relapse takes place. Violent mode of living, and a relapse takes place. Violent headache generally accompanies all the forms of grippe with high temperature.

As to the treatment of grippe, it was commonly believed that there was no specific for the disease, but quinine in large doses was good practice. However, according to Dr. Barbary, of Nice, cacodylate of guaiacol is about the nearest thing to a specific. Introduced into the therapeutics of influenza by Dr. Burlyrgany, who found that one or two injections of troduced into the therapeutics of influenza by Dr. Burlureaux, who found that one or two injections of 1 gr. lowered the fever with astonishing rapidity, cacodylate of guaiacol was made the subject of special study by Dr. Barbary, who, after employing it throughout last winter in all the cases of grippe that came under his observation, arrived at the following conclusions:—Cacodylate of guaiacol had the best effects in persons suffering from grippe, it attenuates the infecin persons suffering from grippe, it attenuates the infec-tion, rendering it benign; injections of cacodylate of guaiacol lower the temperature and rapidly improve the condition of the patient; convalescence, which in many cases is very prolonged, is much abridged; lastly, cacodylate of guaiacol prevents complications so frequently observed in patients of advanced years.

The dose is 1 gr. morning and evening in subcu-

taneous injections.

TREATMENT OF CONVULSIONS.

Convulsions in children are very frequent, as every practitioner knows, and always cause grave anxiety to the parents, who expect prompt treatment from the medical attendant.

The first thing to do where the child is over two years old is to order an enema of salt, oil, glycerin, or honey, and provoke vomiting by tickling the uvula or by a vomitive, for generally the eclampsia is due to some gastric or intestinal disturbance, from simple indigestion to dyspepsia, serous summer diarrhea, or, on the contrary, to constipation; worms are exciting agents.

If the attack continues, a few drops of chloroform or ether may be poured on a handkerchief and given to the patient to inhale largely. A simple warm bath is preferable to a mustard bath, which tends to excite the convulsions rather than allay them.

As soon as the child has "come round," it should be put back into its bed, and the treatment renewed if the convulsions return. The seizure should not in any case be considered as ended until the patient has urinated abundantly.

Other methods have been recommended: Compression of the carotids by means of one or two fingers. To avoid dragging on the skin, and consequently compressing the larynx, the skin should be first pinched up and drawn towards the larynx; to avoid compressing the jugular vein, by which cerebral congestion would be increased, it is best to employ but one finger on the artery. Leeches only find their indication in two cases—uræmic convulsions and venous congestion of the brain. Chloral should be given with caution and in fractional doses every 15 or 30 minutes, taking the age of the patient as a guide: infants, 1 to 3 grains; from two to six years, 4 to 6 grains; from ten to twelve, 3 to 10 grains. A chloroform odour of the breath indicates that the drug should be discontinued.

Bromide of potassium or of calcium may be employed alone or associated with chloral.

Berthez and Demme preferred bromide of ammonia to other bromides, its anti-congestion properties being better marked.

Ritten (Berne) advised atropine in hypodermic injections in children over 6 years of age (1/64 to 1/32 gr. per 24 hours).

Valerian is sometimes useful given in enema:-

Valerian root, 1 to 4 dr. Boiling water, 3 oz.

Add:-

Chloral, 2 to 10 gr. Musk, 1 to 4 gr. Yellow of egg, No. 1.

GERMANY. Berlin, March 28th, 1909

AT the Medical Society Hr. Julius Ritter gave an address on

STREPTOCOCCI IN DISEASES OF CHILDREN AND TREATMENT BY ANTITOXINS.

He described the occurrence and importance of streptococci in the most varied diseases, where they were mostly without significance, at least not specific, as in articular rheumatism. They gained a certain known importance in mixed infection with the bacilli of diphtheria. In scarlatina they were by no means so constant; they were sometimes found in very mild cases, whilst they were sometimes absent in the gravest The agglutination test of scarlet fever serum with streptococcus bouillon was always positive, on the other hand, even with extreme dilution. From numerous clinical observations it appeared that the pathogenous activity of streptococci depended in the first instance on the nutrient soil, on the tissues on which they grew. He was strengthened in this view by examinations of the blood of patients suffering from recurrent erysipelas; in these he found the white blood corpuscles reduced to 4,000 or 4,500.

In his investigations he had made use of the Aronsohn and Hoechster serums. He first treated 22 cases of erysipelas in children, where the fever diminished on the second day and entirely disappeared on the third. The doses given were 20 cc.m. of serum to each no kg. of weight. Four phlegmons starting from the umbilicus, all died. Of 19 bad cases of scarlatina 10 recovered, the rest died. Fourteen cases of septic diphtheria were treated with diphtheria and streptococcus serum; 6 recovered, 8 died. After these experiences the speaker considered that treatment with streptococcus serum should be further tested in appropriate cases.

Hr. F. Meyer said that practically the period of time for the injection was of importance, the injection should be made before the symptoms of general sepsis had become pronounced. Lately attempts had been made to use the serum locally in the form of powder.

Hr. Peiser pointed out the great differences there were in children, as regarded the dangers of infection, due to their different conditions as to nourishment, Breast children were distinctly less endangered than bottle children. It was possible that these differences were of importance as regarded the efficiency of serum treatment.
Hr. F. Schlesinger had seen a good effect from serum

treatment in one case of septic scarlatina. Two of a family became ill, apparently both equally so; one child died in three days without any injections, the other visibly improved after injection and recovered.

Hr. Th. Landau had treated 15 cases of puerperal fever with serum; two died. As soon as the diagnosis was certain 100 cc.m. of serum were injected, after which one litre of saline solution was given, and the day after large enemata of the like solution. The temperature had generally fallen to normal in 36 hours, if it rose again 50 cc.m. more serum were given, some-times even a third dose was given. The effect on the pulse was rapid, it only failed to be seen in the two cases that were fatal. How far the saline infusion assisted in the good result was not certain. The calmative effect was remarkable, the sleep that had been long wanting sometimes came on even whilst the injection was going on. He was of opinion that failures occurred when the medicine was given too late, or not in sufficient quantity. The treatment was contraindicated where local lesions were present.

Hr. Liepmann pointed out the great difficulties there were in the way of an exact estimate of the value of the remedy in a disease so varying as to prognosis as puerperal fever. He had given the serum prophylactically in 100 cases; r had died. In the 100 control cases there were no deaths.

Hr. Aronsohn pleaded for State manufacture of the serum. It was still far too dear. too cc. m. cost 40 mark.

# AUSTRIA. Vienna, March 28th, 1909.

DIAGNOSIS OF NASAL DISCHARGES.

CHIARA in his clinical lectures tells us that chronic discharges from the nose are somewhat misleading if not carefully differentiated. For instance, chronic catarrh with a profuse discharge is a rare condition to meet with, and is more likely to be associated with some of the dependent parts of the nasal cavity. Syphilitic ulcers and necrosis are not uncommonly the cause of many of these chronic conditions. The discharges in these cases are usually bilateral, associated with an evil-smelling discharge, a stabbing sensation, with the surroundings chafed and irritated. Close examination may locate the ulcer, which the sound will confirm by the grating on the bone. The periosteum is usually swollen and painful over a wide area, and the history of contagion a decennium previously is sufficient to confirm the diagnosis, without any other symptom of syphilis being present, except this gumma or necrosing ulcer in the cavity. Foreign bodies and rhinoliths are also fruitful

causes of chronic discharges when they have existed for any length of time, but these are usually recognised by being unilateral. The discharge is also offensive, but the sound increases the flow by relieving the obstructions.

In the case of ozena both sides are equally affected with offensive odour and discharge, even when the atrophic process is well advanced, this symptom is prominent.

when one of the neighbouring canals is affected the purulent discharge is also unilateral, the secretion appearing mostly in the erect posture, hence early in the morning after the night's rest. This discharge is usually thin or fluid pus leaving a hard dry crust in its trail. This fluid may or may not have a slight order. odour, but none as a rule.

SYPHILIS AND NURSES.

Pollak called attention to the abuse of those institutions where children are taken in to be nursed on the breast by showing an infant three months old with well marked congenital syphilis. The infant had been taken into the institution eight days after birth. and kept there at the breast of a nurse till a fortnight ago, when it was discovered by accident. Surely, he said, a remedy can be found for this destructive practice. He proposed recommending the Government making this penal, and placing all such institutions under the guidance and direction of a specialist.

STRUMECTOMY AND TETANY. Boese gave the members an exhaustive account of an operation he performed on a female, æt. 20, for a colloidal enlargement of the thyroid and tracheal compression. Ten days ago after tying the two inferior thyroid arteries and removing the two inferior horns of the gland; the posterior capsule and pale parenchymatous sheath with upper horns of the gland were left intact, severe tetanic fits set in about 24 hours after the operation, which continued for two days without intermission, notwithstanding the application of para-thyroid extract and an alkaloid. After two days had passed and the case looking hopeless, it was resolved to transplant a few epithelial bodies taken from the thyroid of another healthy woman and implant in the peritoneal cavity. The heroine who provided the remedy left the hospital a few days after, and is now perfectly well. Immediately after the transplantation the patient began to improve, the tetanic fits receding. On the third day after the implantation the patient expressed herself perfectly well and free from any spasm.

Bence Jones' Albuminuria.

Gerber related the history of a case of albumose which he diagnosed as Bence Jones' albuminuria, from the peculiar behaviour of the urine with acetic acid. The patient was a male, æt. 56, who was found to be diabetic, with 0.6 per cent. of sugar in the urine. When acetic acid and potassa ferro-cyanide were added, a cloudy deposit forming \( \frac{1}{2} \) per cent. was thrown down, but in the albuminometer it was over .12 per cent. The Buiret reaction, with a weak solution of Cu SO<sub>4</sub> and liq. potassæ was tried, and a pronounced red colour was produced. After this the angle of rotation was to the left, indicating the presence of 2.1 per cent. of sugar, although the rotation was to the right at the commencement.

With concentrated acetic and nitric acids the urine assumed a dense cloudy appearance that rapidly became gelatinous. After the failure or negative condition of the alcohol and ammonium sulphate test, he concluded that the patient was suffering from Bence

Jones' albuminuria.

HYPER-IDROSIS MANUUM.

Freund showed a case of liquitive perspiration in the hands, which he successfully cured by means of the Röntgen rays. After six sittings of six minutes, large lamellæ of the epidermis can be seen lifting off the hands. Below these plates the young skin is pale and dry, but at the margins of the radial application, where the rays were not so intensely applied, the parts seemed moist and soft, indicating that the curative effect was not so complete where the radial effect was weak.

HEALTH OF VIENNA FOR JANUARY.

The official report of the two benefit societies of Vienna has just appeared for the month of January, which may interest the sanitary statistician. There are 310,000 members, of whom 280,000 belong to Venna proper, the others to the suburbs. The number laid up from accidents and sickness during the year were 71,464. Of these, pulmonary tuberculosis claimed 1,138, influenza 562, simple pulmonary inflammation 54, while a miscellaneous number of other pulmonary affections embrace 2,018; angina, or throat affections, 592; diseases of the circulation, 371; stomach and bowel, 728; rheumatism, 1,210; and injuries, 1,746. The number of deaths was 319, of which tuberculosis claimed 151, or 47 per cent.! respiratory organs, 34; circulation, 35; neoplasms, 23; injuries, 10; and suicides, 7.

This only represents the industrial or trade societies of Vienna, not the entire population, which is heavily

afflicted with tuberculosis.

# HUNGARY.

Budapest, March 28th, 1909.

At the recent meeting of the Nagyvarad Medical Society, Dr. Schiff read a paper on

ACUTE ARTICULAR RHEUMATISM IN CHILDREN.

He enumerated quite a goodly number of authors who reported cases of rheumatism in the very young, although this disease is comparatively rare in children. It is possible to admit that the disease is transmitted with the milk of the wet nurse. The incubation period in such cases is at least four days, the duration of the disease between two and four weeks; both the duration

and the severity of the disease are less in infants as compared with adults. In the former it may run its course without any complications, while in older children endocardial and pericardial complications, as well as implication of the pleura and nervous system (chorea) are of frequent occurrence. This has been reported by Baudelocque, Rilles, and Bartez, and others. Picot found 50 per cent. of his cases complicated with pericarditis, while Roger asserts positively that every rheumatic child's heart is bound to be attacked sooner or later. The author observed in his case a rather rare complication in the form of an effusion into the maxillary joint.

LOCAL ANÆSTHESIA WITH ADRENALIN COCAINE.

Dr. Konràd said that it has been observed long ago that a part rendered bloodless is much easier narcotised; thus the application of an Esmarch bandage tends to increase the anæsthetic property of cocaine injected into the bandaged part. Adrenalin is known for its decided vaso-constrictor effect, and the lecturer uses a preparation of the drug with cocaine to enforce the effect of the latter in the following mixture: To a 5 per cent, solution of cocaine-hydrochlorate there was added a 1 to 1,000 solution of adrenalin in the proportion of 2 drops to each c.c. of the cocaine solution. The lecturer employed this mixture for local anæsthesia in 42 cases, including such as lipoma of the external genital organs, phlogmon, epithelioma of the right cheek, cancer of the lower lip, chronic ascites of the atheromatous tumours of the forehead, fistula of the lower jaw, and so on. In all of the cases there was induced complete anæsthesia, there was an entire absence of any parenchymatous hæmorrhage, the anæsthetic effect being observed also on the diseased tissues. Dr. Konrad failed to observe any harmful effects of the mixture on the course of healing, nor were there any immediate toxic symptoms, with one exception. Anæsthesia began ten minu es after the injection, and lasted for almost two hours, thus enabling the operator to stitch up the wound pain-lessly. In operating in deep tissues it is preferable to use weaker solutions of cocaine, but in greater quantity. Some authors advise caution in old people and in children. It is a mistake to assume that local anæsthesia may only be employed in so-called minor surgery, for at a recent meeting of Budapest surgeons reports were made of the successful use of local narcosis in such capital operations as hernia, appendicitis, laryngeal growths, etc.

THE ARTIFICIAL INTERRUPTION OF GESTATION BY BOUGIES.

In a recent number of the Orvosi Heti Kemle, a paper is published by Dr. Jakoby on the above subject. The paper is based on a series of 228 hospital cases, and the procedure employed is as follows: The patient is given a cleansing bath and the outer genitals washed with soap and water, but the vagina is not disinfected. The cervix is then seized with one or two bullet forceps, and a bougie (diameter, 8 to 10 mm.), provided with a stylet, is gradually introduced, while guided by the finger and the stylet slowly withdrawn. The bougie may be carried up between the bag of membranes and the uterine wall without any trouble. In 191 cases one bougie was sufficient; in 21 two were necessary; one bougle was sumcient; in 21 two were necessary; in 2, three; and in 1, four. The average time before rupture of the membranes took place was 24 hours, to the completion of labour 31-45 hours. The nearer the end of pregnancy the procedure was instituted the more readily were labour pains elicited. The entire morbidity is stated by Jakoby to have been 6.8 per cent. in the 228 cases. Three cases of fatal issue may be ascribed to the employment of the method, two of these being through sepsis and one peritonitis. In the latter case the bougie failed and Cæsarean section was resorted to. In 114 cases the pregnancy was interrupted for narrow pelvis; in 65 of these labour came or spontaneously; in 49 artificial delivery of these children was found necessary, 65 per cent. lived. As the morbidity rate is not higher than that of institutions in general, the method may be looked upon as quite free from danger and affording a favourable outcome for the child. The simplicity of the method and the frequency with which the labour terminates naturally,

makes it superior to the dilating bags, which practically means the introduction of an accouchement force, or to vaginal section.

332 THE MEDICAL PRESS.

# LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

"DOCTORS AND MIDWIVES."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Nearly half a century of professional life tells me the value of a well-trained nurse, and how invaluable she is to a medical man when he has no other helper. Take a medical man in an out-of-the-way district, who is called to a case needing prompt operation. He has no helper but the nurse, and

cannot wait to send for any help, and, perhaps, if he did send could not get it. Would it not be of service to him, and his patient, if the nurse knew how to give chloroform, and to hand him the instruments needed. to "lock" them, and know she is doing exactly what he wants? Or, there is a bad case of post-partum hæmorrhage, and he is engaged in controlling it by compression of aorta; the patient is moribund, and he turns to the nurse—for he must not relax his hold—and desires her to "give a hypodermic." The medicaments are all there, and he tells her which to use; she knows (having been taught) exactly what to do, and does it to his entire satisfaction. If she knew, neither what to do, nor how to compress aorta, he must leave

his post—and with what result? I do not for one moment wish to supplant the medical man or woman—and I am sure the welltrained nurse will not either-or deprive them of their fees; and I think it a monstrous shame that while the Act was in Parliament, provision was not made refees when medical help is needed by the nurse and her poor patient!

I well know how magnificently generous and nobly self-sacrificing doctors are, and always contended they should be paid; and when I say "the nurse will always be sending for a doctor," I refer to cases of defective practical nurse-training, or where, if she had been trained, and been out of a berth (and, as Dr. Duke humorously puts it, not been at a birth) for some time, and forgotten her once-acquired knowledge, she would be sending for a doctor when there is absolutely no need, and the patient's friends would not, or could not, pay his fee. I have known a kind-hearted doctor often go when a nurse sent, and find no cause (save her ignorance) for sending, and at length decline to go—not because he did not get a fee, but because of his having been sent for without cause as regards mother and child.

Since the sixties I have been training, having experienced the great need for it; in '79 I began to train for work in those places where women only are allowed to attend the women and their children, and gave the pupils all the knowledge, practical experience and skill possible, so that they could act where no help was otherwise to be had, and where, but for their skilled aid, death would claim both mother and child: At home I would have the nurses always call in the doctor—when she, being well trained, knows when he is needed—but I would not have doctors teased by being summoned, simply because the fault lay with the want of knowledge of the nurse.

I do not teach nurses to circumcise, but to be able to know for certain when phimosis exists, and the resulting evils, if not attended to, and inculcate on them their duty—to tell the doctor in attendance.

Vaccination and other subjects I teach, and have for years, for I know the immense value of being able to do it when nurses are away in such places as Africa, China, Burmah, etc., where no doctor is at hand; and I have no cause to regret that such training has been given, especially as those trained did not interfere with any doctor—man or woman—and were benefactors, where otherwise there would have been no help.
I am, Sir, yours truly,

G. DE G. GRIFFITH.

London, March, 1909.

P.S.—Since writing the foregoing, I have come across the following in the Nursing Times of May 30th, 1908:—"Mr. Haldane, Secretary of State for War, gave prizes to the nurses of the Edinburgh Royal Infirmary for materia medica, gynæcology, bacterio-logy, besides those for nursing. In the course of his speech he spoke of 'the great improvement which had speech he spoke of 'the great improvement which nad taken place both in the position and in the training of nurses within recent times.' He said: 'Many people said that there always were nurses in the medical profession, but there was very little in common between the training of a nurse of long ago and that of the present day.' He compared the doctor to the architect who place the building and leaves the carry. architect who plans the building, and leaves the carry-ing out of his instructions to his contractors. The work of the nurses was part of a scientific whole, and their training must have a scientific basis. He told the nurses that their profession should not be regarded from a money-making point of view. It was one in which the keenest interest could be taken for its own sake. Both knowledge and imagination were required in dealing with a sick person, and the greater knowledge they possessed the more they could be helpful. He added it had been a great pleasure to him to be present that day, and congratulated them warmly on the progress their profession was making."

#### MEDICAL INSPECTION OF SCHOOL CHILDREN

To the Editor of THE MEDICAL PRESS AND CIRCULAR. To the Editor of THE MEDICAL PRESS AND CINCULAR.

SIR,—To those of us who, like myself, pride ourselves upon being patriots first and doctors afterwards, the paper by Dr. Carpenter, and your leader upon it this week, afford sorry reading. There cannot be any doubt that, as at present organised, the medical examination of school children throughout the country 18, even from the merely statistical point of view, of very little value, and as no treatment of discovered defects is provided for, it is even of less practical importance. The reports of the medical officers of boroughs in this part of Surrey tell the same tale as that disclosed by Dr. Carpenter. In a neighbouring semi-rural and wealthy "residential" borough of 25,000 inhabitants, only 60 per cent. of parents took the trouble to accompany their shides the trouble to accompany their children on examina-tion day. Several hundreds out of the few thousands at the schools were found with verminous heads; carious teeth with septic mouths were the rule; whilst adenoids and large tonsils, ringworm, and all the small but disabling ailments affecting children were present in great numbers. Children kept from school because they were "not well" wexe found suffering from diphtheria, scarlet fever, and measles. The attempt at elucidating the condition of the children served more than anything to reveal the fact that a vast proportion of the parents were devoid of all knowledge of the management of children, many culpably careless, and many almost criminally neglectful. It must be borne in mind that at this period of the twentieth century in this enlightened England there still exists the necessity for a Society for the Prevention of Cruelty to Children, which justifies its existence by successful prosecution annually in thousands of cases of cruelty. My point is that in Germany they have for many years been taking preventive measures which we are now only beginning to think about. Not only in this, but in every direction of social organisation, the Germans are surpassing us. If this goes on, our Fleet, however predominant, will not save the Empire from ultimate ruin.

I am, Sir, yours truly,
A Provincial Practitioner. Near Reigate, March 25th, 1909.

THE DECLINING BIRTH-RATE To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—From time to time an interesting discussion has taken place in your columns with regard to the import of a declining birth-rate, in which most of your correspondents have held the view that such decline was fatal—or at least detrimental—to the development and maintenance of the British Empire,

and hence to the interests of the English nation. On the other hand, I have on more than one occasion endeavoured to point out and urge that, so far from this being the case, a declining birth-rate in the face of a surplus and unwieldy population was, under all existing conditions (for which I offered reasons) rather a means for congratulation and security than otherwise. Without in any wise affecting to pose as a politician, and with your kind permission, I take the opportunity of referring your late correspondents to the somewhat startling change in the political atmosphere on the recent discussion elsewhere upon the Navy Estimates, which appears, to my fhinking, to give countenance and corroboration to what I have always held, and that is, if we drain our excessive population by means of emigration and the export of our best blood, this procedure must inevitably sooner or later spell national decadence, and hence insecurity of the whole Empire.

Now I think it should be apparent to such correspond to the corresponding to the cor

spondents who have controverted me (at least for the time being) that for the protection of our shores, and for the mere purpose of defence, the population, both from a numerical and hygienic point of view, should so regulate itself that, in the event of conscription or otherwise becoming an absolute necessity, we may insure an army, to say nothing of a navy, capable of coping with any foreign invader. But what I ask is—whence is the army forthcoming if we export our best product to build up an Empire, leaving our own shores as an asylum for the decrepit and destitute, which your correspondents have, as appears to me, hitherto practically insisted upon?

I am, Sir, yours truly,

CLEMENT H. SERS.

Brighton, March 29th, 1909.

LAW FOR DENTISTS AND LAW FOR DOCTORS. To the Editor of The Medical Press and Circular.

Sir,-On numerous occasions you have allowed me to record in your pages illustrations of the grotesque auomalies in medical law as presented in reports of police court proceedings in the daily papers. The Times of to-day publishes two of such cases, both heard yesterday at the North London Court. In the first instance, an unregistered man had, among other titles, used the qualification, "dentist." He was fined £15 and £3 3s. costs. In the second case a man, also unregistered, had not employed the title "dentist," but had advertised under cover of a "teeth institute." He was fined £10, with £3 3s. costs. If an unregistered medical practitioner assumes a title specifically enumerated in the Medical Acts he may perhaps be fined; but he cannot be touched if he employs bogus titles, or if he practices under cover of a "medical institute," and uses language in his advertisements calculated to lead even educated readers to take him for a qualified practitioner; and he cannot be interfered with if he practises under the cloak of selling nostrums or apparatus, and advertises them under the name of a fictitious doctor, with the effect of making the customers who consult him believe that they are being treated by a qualified man. Not only in dentistry, but, as you have allowed me frequently to point out, in veterinary surgery also, these abuses are not permitted. They continue to exist in the medical profession because the profession remains politically impotent—has no voice, and no means at present of making itself effectually heard even if it had a voice.

I am, Sir, yours truly,
An Obscure Practitioner.

March 16th, 1909.

# **OBITUARY.**

LT.-COL. TUOHY, M.D., M.CH., Q.U.I., M.A., I.M.S. (Ret.).

LIEUT.-COLONEL TUOHY, who died at Brighton, in his 54th year, on February 22nd, was a distinguished officer of the Indian Civil Service, having taken part in the last Afghan Campaign, for which he held the medal. He was stationed for a year at Kandahar

after its occupation. He held the position of Police and Civil Surgeon for 17 years under the Government of the North-West Provinces, and was the first Super-intendent appointed to the Ramsey Hospital Naini Tal, the largest hospital for Europeans in Northern India. Here he held the post of Police and Civil Surgeon, which he also filled at Allahabad, Agra, and Saharapur. At Agra he was Superintendent of the Medical School, and the Colvin and Lady Dufferin Hospital, being a member of the North-West Provinces Committee of the Lady Dufferin Fund. On many occasions he received the official thanks of the Government for the manner in which he performed the duties of Civil Surgeon. Of late years, after his retirement from the service, he followed private practice at Hove, Brighton.

During his service in India he earned for himself a high character for his administrative powers, to which, on several occasions, testimony was given by the heads of the Indian Medical Department. His unexpected death occurred after a comparatively brief illness, and has been greatly regretted by all his old colleagues in the service, and by a wide circle of friends, for he was a man whose personal character endeared him to all who knew him. He was, in the words of one of the chiefs of the Indian Service, "a thorough gentleman, conscientious and tactful in his dealings with others."

SURGEON-MAJOR WILLIAM GALT BLACK,
F.R.C.S.Ed., M.R.C.S.
WE regret to record the death of Surgeon-Major
William Galt Black, a Crimean veteran. He was
born in 1824 at Bolton, where his father, the late Dr.

James Black M.D. who was a Newton Stawart James Black, M.D., who was a Newton Stewart native, was in practice. The deceased gentleman was educated in Manchester and at Edinburgh University. He joined the 11th Foot Regiment, now the Devon-shire Regiment, shortly before the outbreak of the Crimea War, and he served right through that arduous campaign. He was present at the battles of Alma, Inkerman, and Sebastopol, and possessed a number of medals. At the conclusion of the war he served for 10 years in Africa, and he had also other periods to form coving acres to his archibit and the content of the server of of foreign service to his credit in the course of his connection with the Army, from which he resigned 26 years ago. On his retirement he went to reside at 2 George Square, Edinburgh, and devoted his attention to scientific studies. He was a member of the tion to scientific studies. He was a member of the Society of Arts, and in 1883 won the Brisbane prize of that Society for a marine anemometer, which he afterwards exhibited at exhibitions in Liverpool, Manchester, Glasgow, and Edinburgh.

FREDERICK HARCOURT GERVIS, M.D.BRUX., M.R.C.S., L.R.C.P.

WE regret to announce the death Frederick Harcourt Gervis, of the Royal Army Medical Corps, aged 37. Captain Gervis entered St. Thomas's Frederick Harcourt Gervis, of the Royal Army Medical Corps, aged 37. Captain Gervis entered St. Thomas's Hospital as a student in 1891, and obtained a science scholarship as a result of his first year's study. In 1896 he qualified as a member of the Royal College of Surgeons and as a licentiate of the Royal College of Physicians, and two years later he obtained the M.D. degree at Brussels. He was appointed a House Surgeon at St. Thomas's Hospital, and at the Paddington Green Children's Hospital he held, at various times the posts of House Surgeon. House Physician. times, the posts of House Surgeon, House Physician, and Clinical Assistant.

For many years Captain Gervis was closely connected with the Volunteer movement, and was Surgeon - Lieutenant, and subsequently Surgeon-Captain, of the 17th Middlesex Volunteer Rifle Corps.

DR. C. COATES, OF BATH.

DR. CHAS. COATES, who had retired from practice about ten years, died at the age of 83 on Wednesday last, and was the oldest member of the medical profession in Bath. Dr. Coates was a liberal supporter of the Bath charitable institutions. He was honorary consulting physician to the Royal School for Daughters of Officers of the Army, Lansdown, a trustee of Partis College, and also of Holburne Museum. He gave £1,000 to the Bath Blue Coat School and a similar sum to the Royal College of Physicians to found a prize. Dr. Coates became a Fellow of the Royal College of Physicians, Edinburgh, in 1857, and of the Royal College of Physicians, London, in 1873. He was formerly resident clinical assistant at the Hospital for Consumption at Brompton.

# SPECIAL ARTICLES.

# THE TYPHOID OUTBREAK AT CLONTARF.

SIR CHARLES CAMERON, Medical Superintendent Officer of Health for Dublin, has published, in the form of a Report to the Dublin Corporation, an interesting account of the outbreak of typhoid fever

which occurred last autumn at Clontarf.

which occurred last autumn at Clontari.

The area affected by the epidemic contained 748 houses; of these, 193 were supplied with milk from one dairy, and 555 from 28 other dairies; 82 of the houses were invaded by typhoid fever, and 127 of the inmates became victims of the disease; 79 of the 82 houses were supplied with milk from the suspected -that which supplied 193 of the houses. As to the other 3 houses, it was found that they also had occasionally received milk from the suspected dairy.

The milk from the dairy and specimens supplied by it to houses in Clontarf were examined bacteriologically, and no micro-organisms characteristic of typhoid fever were found in them. As Sir Charles Cameron points out, it is only rarely that typhoid bacilli are discovered in milk. The dairy was bacilli are discovered in milk. The dairy was examined and found clean and well-kept. The cows of the dairy numbered 58, of which 13 were within the curtilage of the dairy. The remainder were in pastures quite separate from it. The milk from the pastures was distributed direct to the customers, without being brought to the dairy itself. No member of the dairyman's family or staff had recently been ill, and it could not be found that any had ever had typhoid fever. On the suggestion of Sir Charles Cameron, the proprietor of the dairy obtained the services of a bacteriologist to examine all persons connected with the service of milk. The result of the examination was never made known to Sir Charles Cameron, but one of the men employed as milkers was subsequently transferred to other employment. Previous to this, the dairyman's solicitor had made an application to the Local Government Board to hold a sworn inquiry into the cause of the epidemic, but the Board declined. The solicitor subsequently applied to the King's Bench for a mandamus compelling the Local Government Board to hold the inquiry, but he withdrew the application. The withdrawal was made after the bacteriological examination had been carried out.

When satisfied that the outbreak appeared to be due to infected milk, the question arose: How should action be taken to restrain the sale of it? If a case of fever had been found in the dairy, or that any person connected with it was, or had been, recently ill, the Public Health Acts and the Dairies and Cowsheds Orders could be employed for the purpose. In the absence of any knowledge of disease in connection with anyone in the dairy. Sir Charles Cameron consulted the Law Agent of the Corporation on the subject. He was of opinion that in the existing state of the law no legal action could be taken. The Assistant Law Agent was of the same opinion.

The Local Government Board, however, and their advisers were of different opinion, and the Board advised the Corporation to take legal action against the proprietor of the dairy in order to stop the supply of milk. The opinion of senior counsel was taken by both parties, and no legal action ensued. The case submitted to counsel by the Law Agent of the Corporation contained the following query:

"In view of the fact that there was no direct evidence to show that the milk of this dairy caused and is causing the spread of typhoid in the district, can

the Corporation take any step to compel the owner to discontinue the supply of milk in the district of the City of Dublin?"

We entirely fail to see any justification in the facts, as Sir Charles Cameron recounts them, for the statement in this query. With such a case put before him in such a manner, it is hardly a matter of surprise that counsel advised against any action. Senior counsel consulted by the Local Government Board, on the other hand, remarked:

"The case is one of much difficulty and doubt, but my own opinion is that a court could, under the terms of the section, and would in the circumstances, construe the section so as to bring the case within it, having regard especially to the paramount object of the section, and of the entire Act being the preservation of the health of the community by preventing the spread of disease. I do not agree with counsel that the section must necessarily be construed in the very strict way in which he looks at it. It is entirely remedial as regards the public, though penal as regards the dairyman, and should be construed with reference to the true meaning and real intention of the legislation, which was to prevent the spread of disease.

By this time, of course, the outbreak had almost subsided, and no legal proceedings were taken.

During the investigations made by Sir Charles Cameron and Surgeon-Colonel Flinn, of the Local Government Board, it came to their knowledge that a case of illness, stated to be typhoid, had occurred in August in a house whose yard was in close proximity to the yard of the dairy. During August the discharges from the patient passed down a sewer made of stone. At a right angle from the sewer, a com-bined drain extended to the dairy premises. This drain had neither an interceptor nor a ventilator.

In the month of August, 1908, the sewer was opened near its junction with the drain, and a quantity of "black stuff" was taken out of the sewer and placed on the surface of the lane, where it remained for three or four days. This work was done by the Corporation workmen, or by contractors' men in connection with the main drainage works.

Sir Charles Cameron states his opinion that the outbreak was due to the infection of milk by a typhoid carrier, supposed to be one of the men employed as milkers. He believes that the alleged case of typhoid occurring in August had nothing to do with the out-break. We do not find his argument quite convincing. The theory that one of the milkers was a typhoidcarrier is an assumption, with no direct support except the alleged fact that he was removed to other work after being subjected to bacteriological examination. On the other hand, we have a case regarded by a medical man as typhoid, though not notified, in immediate proximity to the dairy-yard, where the vessels used for carrying the milk were washed. The drains were in connection, and unprotected, and in addition, for some length of time, the contents of the drains were exposed freely in the lane adjoining the dairy-It is true that there was an interval of some vard. weeks between the first exposure of the sewage material and the beginning of the outbreak, but the difficulty of explaining this interval is not as great as that of explaining why the milker should suddenly cause a fulminating outbreak. The milker is not said to have come recently into the employment of the dairy proprietor, and there is no reason to suppose that cases of typhoid had ever arisen from him before. In the history of most carriers we find several cases scattered over a period of years, and not one sudden outbreak. In fact, the only new feature in the history of the dairy was the probable case of typhoid close at hand, and the exposure of the sewage by the Corpora-tion workmen. We cannot understand why a dairyyard, subject to inspection, had been permitted to remain with an unprotected closet-drain, until the outbreak of typhoid drew attention to the condition.

The failure of the Corporation to take legal proceedings is insufficiently justified, the case for counsel's opinion being much less strongly stated than might with accuracy have been done.

# REVIEWS OF BOOKS.

COMMON AFFECTIONS OF THE LIVER. (a)

THE author, in his preface, explains that this work is a compilation of such notes as he had used for his clinical lectures, dealing with diseases of the liver, arranged in book form. He makes for it the modest claim that it is intended for students beginning their work, and not for those who have extensive clinical knowledge; yet, after reading it, we are left wondering what more of importance there is to say, and what the larger text-books contain which swells them to their more pretentious proportions. After a brief account of the anatomy of the liver, and of displacement of that organ, the subject of jaundice is fully dealt with. Here we notice that no attempt is made to adhere to the old division into obstructive and non-obstructive jaundice, but causes of obvious obstruction are first given in the order of the frequency of their occurrence, and afterward the causes of less obvious obstruction. In this way the old clinical distinctions remain, whilst the arrangement clinical distinctions remain, whilst the arrangements is accurate in accordance with more recent experimental work. Further on, 34 pages are devoted to a description of large single abscess in the liver, a somewhat large section of the work, considering the comparative rarity of this disease in England. Whilst all will agree with the author when he states that in a case of uncomplicated hepatic abscess the pus should be let out, we think that his teaching in respect to an abscess which has ruptured into the lung will be less generally accepted. His advice is to let well alone, and not interfere unless there is indubitable evidence

that the patient is losing ground.

This is followed by an especially useful chapter on suppuration about the liver, in which the author shows his close acquaintance both with the practical side of the subject and with the late Mr. H. L. Barnard's work on subphrenic abscess. We note that he uses the truth that subphrenic abscess is equally common in the two sexes as evidence in favour of his contention that gastric ulcer is equally common in men and women. Here, again, in the matter of treatment we think there is room for difference of opinion. Many would not agree that a subphrenic abscess should be left unexplored for 14 days after it had been suspected. A great point is made of the important clinical sign that the liver is not displaced downwards in this condition, for it is mentioned in at least four places (pp. 10, 107, 121, and 125), but this is only partly true, for, as Mr. Barnard has said, in the right extra-peritoneal variety it may be displaced downwards as far

as the umbilicus.

The next section, which concerns cirrhosis of the liver, contains many original and interesting suggestions. Hypertrophic cirrhosis is regarded as an early stage of the atrophic form, and not, as some authors believe, as a distinct variety. It comes somewhat as a surprise to learn, on p. 147, that piles are uncommon in cirrhosis of the liver. The author makes a good case for ascribing the ascites to the action of a toxin, and not, as is usually supposed, to portal obstruction, and he emphasises the gravity of this symptom by stating that patients in whom it occurs usually die in a few weeks. Under treatment, he says, "unless the quantity of fluid is so great that it hampers the movements of respiration or a the total of the contraction of the co the movements of respiration or pushes the heart out of place, there is nothing to be gained by letting it out." This teaching is directly opposed to that of certain other authorities, one of whom advised, in a recent Lumleian lecture, that ascites in such cases should be tapped early and often. This difference of opinion is probably due to the recognition or otherwise of the individuality of perihepatitis, on which the author lays so much stress. No instruction is given to see that the bladder is empty before inserting the trochar. In the chapter on perihepatitis, the author summarises his work on the subject, and states his well-known views.

The last 80 pages contain, besides sections of less clinical importance, an account of malignant disease

of the liver and of hydatid cyst. The sections dealing with fatty liver, lardaceous liver, and tubercle and actinomycosis of that organ, are necessarily largely pathological, rather than clinical.

This volume should prove of great value, not only to the beginner, but to the more advanced student, for it contains in a very readable form all that is of practical use in the recognition and treatment of hepatic

FARABEUF ON MIDWIFERY. (a)

BRITISH obstetricians will extend a very hearty welcome to the new edition of this well-known textbook. There are few books on obstetrics whose drawbook. There are few books on obstetrics whose drawings have been so profusely reproduced by other writers, and whether this is done, as Professor Farabeuf says, "avec indication de leur origine ordinairement, ce qui est bien," or "mais pour toujours, ce qui est mal," the welcome the book will receive is the same.

In the present edition the text and the drawings have been increased. As before, the book only deals with certain subjects in midwifery, and not with the whole of midwifery. The selected subjects are—anatomy, presentations and positions, mechanism of labour, vaginal examination, extraction of the breach. version, and delivery by the forceps. It is easy to-understand that Professor Farabeuf did not wish to include the remainder of midwifery, but there is one omission for which it is difficult to account, namely, the omission of all reference to abdominal palpation and auscultation. This is the more strange as there is a long section devoted to vaginal examination. It is unnecessary to advise any one who has read former editions of Professor Farabeuf's work to read this edition, for they will do so without advice. As for those who have not read them, we can only advise that they make haste to add another span to the stature of their obstetrical knowledge.

ON SPRUE. (b)

The little that is known regarding this disease is only to be found scattered throughout the various medical journals. A monograph on the subject is therefore a desideratum. The volume under review, after dealing fully with the history and literature of sprue, goes on to discuss the symptoms and signs of this disease, which seems to be on the increase in Eastern tropical countries. The morbid anatomy and pathology of the disease are very carefully and fully considered. The author states that the exact pathology of the disease is probably "a specific protozoan or bacterial infection, which gradually spreads from above downwards through the alimentary canal." As yet, of course, no specific organism has been discovered in the lesions or in the blood of patients suffering from sprue, but this does not interfere with the author's explanation as to the actual origin of the disease.

Dr. Carnegie Brown deals at considerable length with the general effects of a milk diet in the treatment of sprue. He says this form of nourishment merely serves to keep the patient alive. It does not check tissue waste, which still goes on. In spite of all this, the use of a milk diet appears to be indispensable. Along with milk, strawberries give good results. The latter should be given as early as possible in the disease. Where fresh milk cannot be obtained, an exclusive meat diet is said to afford very good results. Treatment by means of a purely fruit diet is also referred to the control of the disease. to very fully, as is also the treatment of the disease by means of drugs. The management of complications and collateral infections is dealt with in a very careful and practical manner. In the treatment of sprue alcohol is strongly condemned by the author. There exist "from the earliest to the latest stage of the disease a specific intolerance and antagonism to alcohol in any form."

(a) "Introduction à l'étude clinique et la pratique des Accouchements." Par le Professeur L.-H. Farabenf et le Docteur Henri Varnier, Préface du Professeur A. Pinard. Dessins démonstratife de L.-H., donnant avec les répétitions nécessaires 375 figures dont plusieurs nouvelles. Nouvelle édition revue et augmentée. Pp. viii and 488. Paris: Steinheil, Editeur. 1908.

(b) "Sprue and its Treatment." Bv W. Carnegie Brown. M.D., M.B.C.P. London: John Bale, Sons and Danielsson, Ltd. 1908.

<sup>(</sup>a) "Common Affections of the Liver." By Wm. Hale White, M.D. Lond., F R.C.P., Senior Physician to Guy's Hospital. London: James Nisbet and Co., Ltd. 1909.

The writer insists on the necessity of early treatment, and altogether affords the reader all the information regarding the mode of dealing with this disease which has been collected up to the present time. The book is essentially a practical one, and will doubt-less become the standard work on its subject in the English language. For medical men practising in the Tropics Dr. Carnegie Brown's monograph will be found of very great assistance as a guide to the management and treatment of this somewhat troublesome affection.

DIET IN INFANCY. (a)

This is a well-thought-out little book on the dietetics of infancy and the management of digestive disturbances, and it goes a good deal farther than most works of the kind. The author is very dogmatic, and one feels disposed at times to challenge the statements he makes with such confidence. Has it really been proved, for instance, that boiled milk is less digestible than raw? In any case, there is good authority for the contrary view. Not, however, that this point has any practical bearing on the author's teaching, because he advises the sterilisation of milk all the same. It is all very well for him to instruct us not to give infants milk obtained from "Jersey, Guernsey, and Alderney breeds of cows," but how in the when the second of the second but how is the urban practitioner to discriminate? discussing the employment of condensed milks for infant feeding, of which he approves, the author does not evince any preference for the unsweetened varie-ties—the "Ideal" milk, for example, yet most writers on the subject admit that the presence of so large a proportion of sugar is a drawback.

No doubt it is desirable to keep milk at a temperature below 45° F. until consumed, but it is hardly practicable in most instances, so that boiling and rapid

cooling become indispensable.

The author goes over the ground methodically, and practitioners will not refer to him in vain when in a difficulty. There are some seventy pages of appendices, mostly reprints from medical journals on subjects germane to infant nutrition.

INTERNATIONAL CLINICS. (b)
This volume of "International Clinics" contains twenty-four separate papers, dealing with various subjects of interest in connection with Medicine, Surgery, Therapeutics, and several of the specialities. A careful and useful compilation of cases of "Acute Dilatation of the Stomach" is contributed by Dr. Albert Nicholls, and is introduced by a description of some cases that have come under the writer's own observation. He points out that the most constant feature post-mortem, in addition to the actual gastrectasis itself, is the presence of duodenal obstruction caused by the root of the mesentery. This obstruction he regards as the actual cause of the dilatation, and strongly recomactual cause of the dilatation, and strongly recommends, in consequence, the adoption of a postural method of treatment. Other subjects dealt with under the heading of "Treatment" and "Medicine" are:—"Primary Splenomegaly," by Parkes Weber; "Physical Therapeutics," including a plea for their more extended use in clinical teaching hospitals; "Enteroptosis," "The Treatment of Gastric Ulcer," and "Psycho-therapeutics." A useful paper in the section devoted to Pædiatrics is that on "The Serum Treatment of Epidemic Cerebro-Spinal Meningitis," by Dr. Hunter Dunn. The history of this method of treatment is briefly traced, and the rationale of the method in is briefly traced, and the rationale of the method in its entirety is discussed. Flexner's serum, of course, receives most attention, and a statistical analysis of the cases treated by it is presented. The Surgical section contains five articles dealing with a variety of subjects. Ely contributes his personal experiences with Bier's treatment by passive hyperæmia, and expresses his warm commendation of this therapeutic means. McGregor discusses "Traumatic Lesions of the Semilunar Cartilages and their Treatment." He regards operative measures as alone likely to be

attended with a successful result. Papers on "Fracture of the Skull," on "Pneumococcic Arthritis," and on "Paronychia Lateralis" complete the series. In the other sections the following papers may be noticed:—"Pseudo-Bulbar Paralysis," with account of a typical case, by Dr. Lloyd; "The Rôle of Insects in the Transmission of Disease," by Dr. Brown; and an interesting article on "Bronchial Calculi," hy Clifford Farr. The entire volume forms a collection of readable and interesting practical papers.

YEO'S MEDICAL TREATMENT. (a)

The appearance of a new edition of this extremely popular manual of treatment entails little responsibility upon the reviewer. All that is required by the medical world is the information that the twenty-second thousandth has been reached, together with a brief notice of any fresh features in the work. The third edition came out as recently as 1902, but the rapid growth of medical knowledge has rendered a thorough revision necessary, in which the author has been assisted by Dr. Raymond Crawford and Dr. Farquhar Buzzard. The former has undertaken the parts of the book dealing with diseases of the circulation and digestion, together with those of the liver and kidneys, while the latter has naturally dealt with the nervous system. The peculiar charm of this book lies partly in its admirable literary style, and partly in the system which invests therapeutics with all the essential factors of interest involved under such allied questions as pathology, ætiology, and clinical characters. The present presents an advance on former editions and its general form and appearance, it is hardly needful to add, are above reproach.

# LITERARY NOTES.

THE ninth edition of Dr. E. J. Domville's little "Manual for Hospital Nurses" shows that this meritorious little work has been duly appreciated by those for whom it was written. The text is clear, brief, and to the point, and the whole ground of the nurse's duties is adequately covered.

THE fifteenth edition of Dr. Thomas Linn's "Health Resorts of Europe" displays a healthy tendency to put Resorts of Europe" displays a healthy tendency to put on flesh, short of obesity, and it constitutes a handy guide to the principal health resorts and watering-places of Europe, including Great Britain. We have the hotels and "pensions," lists of doctors and dentists, hints as to amusements, and a reference list of works for the health of these who desire detailed informafor the benefit of those who desire detailed informa-

VERY opportunely at the present moment comes a series of lectures delivered at the West London Post Graduate College on the "Medical Inspection of School Children." The first deals with the general scheme such instructions should take, and the others with examination of the skin, eyes, ear, throat, and nose, and the teeth, by members of the West London Hospital Staff. The information, if elementary, is pleasantly conveyed, and is sound so far as it goes.

MESSES. EVANS, GADD AND Co., Ltd., have issued a little book on "Drugs and Medical Requisites," which is a good deal more than a trade catalogue. It contains a great deal of information of a varied character, and much of it is very useful. The list of synonyms of the trade and scientific names of drugs is instructive. We confess we did not know that pil. colocynth et hydrarg, went by the name of "Abernethy's pills," and several other facts here mentioned.

SIR JAMES SAWYER'S Lumleian Lectures on "Points of Practice in Maladies of the Heart " (Birmingham: Cornish Brothers, Ltd.) were well worth reprinting.

(a) "A Manual of Medical Freatment," By I. Burney Yeo, M.D., F.R.O.P., assisted by Raymond Crawford, M.D., and E. Farquher Buzzard, M.D. New Edition. Two Vols, London and New York: Cassell and Co., Ltd. 1999.

<sup>(</sup>a) "Diet in Infancy." By A. Dingwall-Fordyce, M.D., F.R.C.P.Ed., Estra-Physician to the Royal Hospital for Sick Children, Edinburgh. Edsburgh: Wm. Green and Som. 1968. (b) "International Chisics." Vol. IV. Eighteenth Series. Phila-delphia and London: J. B. Lippincott Co. 1908.

The subject of cardiac disease is discussed from the clinical point of view, and special emphasis is attached to the particular observation of individual cases. are enjoined not to attach overweening importance to stethoscopic examination, a heart case has never been a heart case only; indeed, as physicians, we are much more concerned with the physiological effects of a cardiac state than with the merely local manifestations of the lesion. There is nothing didactic in these lectures; they are chatty observations on points of importance in diagnosis, and diagnosis of heart lesions viewed from the general physician's point of view. Hackneyed as is the subject, no practitioner could peruse the author's thoughtful remarks without adding to his knowledge of the subject.

# MEDICAL NEWS IN BRIEF.

#### The New Physiology Buildings at University College.

THE new Institute of Physiology, although not yet opened officially, was inspected on Saturday last by the members of the Physiological Society, who were enthusiastic as to its capabilities for teaching and for research work. Its usefulness will also be greatly increased when the college authorities have erected two similar buildings beside it—one for the study of anatomy and the other for the study of pharmacology, which enters into the present design.

The laboratory consists of four storeys, and includes

a large lecture-room, capable of accommodating 200 students, without discomfort, and equally large rooms for the study of physiology, of physiological chemistry, and of histology. The special features of the laboratory are, however, the large number of smaller rooms intended for the purpose of research and the theatre has been so constructed that students will be able to see the full details of important demonstrations.

An operation-room has also been built, in which it will be possible to observe the conditions of absolute cleanliness that are essential; adjacent to it is a bathroom, and on the same floor is an animal hospital, where the very best conditions for recovery can be maintained. A special room on the ground floor has been reserved for the purposes of micro-photography. Other features in which the convenience and comfort of both elementary and advanced students have been specially considered have entered into the plans, and the new buildings will greatly enhance the teaching facilities of one of London's most popular medical

# The Nurses' Registration Bill (No. 2).

A SHORT résumé of the Bill introduced by Mr. Findlay, and known as the Nurses' Registration Bill, No. 2, may be of interest to our readers, as it differs in many respects from the Bill on the same subject introduced by Mr. Munro Ferguson. Bill No. 2 proposes to set up a Central Board for the registration of nurses in the United Kingdom, which is to consist of 27 persons. A large element on the Board will consist of matrons of hospitals and nurses, or persons selected by them. A registered medical practitioner, according to the scheme of the Bill, will be appointed by each of the following bodies: the Privy Council, the General Medical Council, the Medico-Psycholo-gical Association, and the Central Hospital Council. The registered nurses of the United Kingdom are to elect a medical man, and three medical practitioners are to be appointed by the British Medical Association. A provisional constitution is provided for in order that certain initial work may be carried out.

The proposed duties and powers of the Central Board are set forth as follows:—"(1) To frame rules— (a) regulating its own proceedings and the times for holding its meetings; (b) regulating the issue of certificates of registration and the conditions of admission to the register of nurses; (c) regulating the course of training and conduct of examinations and the remuneration of the examiners; (d) regulating the admission to the register of persons already in practice as nurses at the passing of this Act; (e) deciding the conditions under which a nurse may be suspended from practising as a registered nurse; (f) defining the particulars required to be given in any notice under this Act. (2) To appoint examiners and inspectors.
(3) To decide upon the places where, and the time when, examinations shall be held. (4) To publish annually a register of nurses containing the names, addresses, and record of training and work of nurses who have been duly registered under this Act. (5) To decide upon the suspension or removal from the register of the name of any nurse for disobeying the rules and regulations from time to time laid down under this Act by the Central Board from conduct disgraceful in a professional aspect, or for other misconduct, and also to decide upon the restoration to the register of the name of any nurse so suspended or removed. (6) To take proceedings against persons guilty of offences under this Act. (7) To issue and cancel certificates of registration, and generally to do any other act or duty which may be necessary for the due and proper carrying out of the provisions of this Act. All rules framed under this section shall be valid only if approved by the Privy Council."

Provision is made for the registration of existing nurses, but at the expiry of three years the Bill proposes that admission to the register should only gained by persons who produce evidence satisfactory to the Central Board of training in the wards of an approved hospital or Poor-law institution, and pass the examination prescribed by the Board, as well as complying with other requirements.

#### A Doctor's Operation on Himself.

AT Newsham, Northumberland, on March 20th, an inquiry was held into the death of Dr. Ephraim Henderson, aged 35, who lived at Newsham. He became seriously ill on March 17th, and on March 18th, during the absence of his wife and a nurse, he inflicted a wound in his throat with a knife. He died the same

Dr. Cromie, of Blyth, said Dr. Henderson had been in his service nearly three years. On March 17th the witness was called to see him, and found he was suffering from Bright's disease of long standing and septic pneumonia. With regard to the wound in the throat the witness said it had evidently been made by Dr. Henderson for the purpose of relieving himself from the pain of his other troubles. The position of the wound, the witness urged, supported the theory that Dr. Henderson did not contemplate suicide. anything the wound in the throat prolonged his life by causing hæmorrhage upon the lungs. Dr. Cromie added that he was of opinion that death was due to Bright's disease, accelerated by septic pneumonia.

The jury accepted Dr. Cromie's explanation of the wound, and entered a verdict to the effect that death was due to natural causes.

### Death Under Chloroform.

An inquiry was held by the Wigan Borough Coroner, on March 16th, as to the cause of the death of Rhoda Howard, aged 22 years, which occurred at the Wigan Infirmary, at 1.30 p.m., on Sunday, after an operation had been performed on her for contracted knee-joints, for which she had been chloroformed.

Benjamn Howard, father, a jobbing gardener, of Back Lane, Shevington, said the deceased had not been in a very good state of health all her life. About six years ago she burst a blood vessel, in consequence of

which she was afterwards unable to walk.

Dr. Buchanan, surgeon at the Wigan Infirmary, stated that deceased was admitted to the infirmary on February 24th, suffering from contracted knee-joints, and it was necessary to straighten the knees with the patient under chloroform. Witness administered the chloroform, and he and Dr. Berrie performed the operation.

The Coroner: In what quantity was the chloroform administered?—I should say altogether there was used about a little over an ounce. Of course, we used the open mask, and with this the largest part of the snæsthetic evaporates in the air.—Before administering the chloroform was she examined?—I examined the heart, and I thought it was all right; I did not recognise anything wrong with it.

Further questioned, witness said that after the operation had been performed; and about a quarter of an hour after he had administered the chloroform, the deceased collapsed, and he and Dr. Berrie resorted to artificial respiration, which they kept up for a little

over half an hour without effect.

The Coroner: Have you had considerable experience in administering anæsthetics?—I have given them about thirteen or fourteen hundred times. I have never had a death.-And the patient's heart may be in a certain condition, which cannot be detected previous to the administering of the anæsthetic, and result in a collapse?—That is so.

What was the cause of death?-I think it was due

to cardiac failure under chloroform.

The jury returned a verdict that deceased died from heart failure under chloroform.

#### Cardiff Doctor's Sudden Death.

MR. W. L. YORATH held an inquiry at Cardiff on March 18th into the death of Dr. William Patrick Brooks, of 10 Constellation Street, a well-known Cardiff medical practitioner, who expired suddenly.

Mrs. Norah Brooks, the widow, stated that the de-

ceased was 39 years of age, and for the past few years had enjoyed fairly good health. On the Sunday evening he had a fit, but soon got out of it. He did not sleep that night, and was not well on Monday. In the evening he took a draught, and was much better on Tuesday. The next morning he complained of being unwell, and stayed in bed. Towards mid-day sent for, but her husband died just before he arrived.

In answer to the Coroner, Mrs. Brooks said the

deceased drank, but never to excess.

Dr. Macgregor, giving evidence, said that he was sent for, and upon his arrival found the deceased had been dead just a few minutes. There were no marks of injuries, and he could not find any trace of drugs. Death was due to heart failure, perhaps following upon the fit which the deceased had on Sunday.

The jury returned a verdict in accordance with the

medical evidence.

## Lener Worker's Death.

THE death is announced of Dr. Smith, the physician at the Tracadie Leper Colony in the Bay of Fundy, after a lifelong work as the volunteer medical attendant of the unfortunate lepers. The colony was originated about the year 1850, when the passengers of a British ship, who developed the disease, were forced to disembark at that point.

#### Sentences for Abortion.

AT Bristol Assizes, on March 26th, before Mr. Justice Ridley, Soloman Fry, 48, a mason, and Sarah Ann Wright, 35, a charwoman, were indicted for the murder of Kate Webster on October 27th last in

murder of Kate Webster on October 27th last in Bristol. No evidence was offered by the prosecution, and a verdict of "Not guilty" was returned.

The same prisoners, together with Clara Lennard, of no occupation, were then indicted for procuring abortion. All pleaded "Guilty."

It appeared that they had carried on the practice for years, and sums varying from 5s. to a sovereign had been paid to them by women. There were 14 cases in Bristol alone against Fry, besides the eight charges preferred against him in the present indict. charges preferred against him in the present indict-ment. Wright was a married woman. The prisoner Lennard was the wife of a collier, and was known as "a married woman's friend," and for seven years had acted as an introducer, but had not actually performed any operations.

Wethered, who appeared for Lennard, stated that she stood on a different footing from the other prisoners. Fry had been originally a respectable and hard-working stone-mason.

Mr. Inskip, who defended Wright, urged that she was respectable until she became acquainted with Fry. Mr. Justice Ridley said that Lennard, who was the mother of six children, and was enceinte, must go to prison with hard labour for 12 calendar months. Wright would be kept in penal servitude for seven years, and Fry must go to penal servitude for 12 years.

#### Medical Sickness and Accident Society.

At the usual monthly meeting of the Executive Committee of this Society, Dr. de Havilland-Hall in the chair, it was reported that the business for the early part of this year was satisfactory. The number of sickness claims received had been large, but on the whole the sickness experience was rather lighter than for the same period of 1908. The number of new entrants is also quite satisfactory, being well above the average, though rather less than in the corresponding period of last year. As no money is paid by the Society as commission, and no agents are employed, the ever-growing number of new entrants is satisfactory evidence that the benefits offered by the Society are appreciated by the profession. Prospectuses and all further particulars on application to Mr. F. Addiscott, Secretary, Medical Sickness and Accident Society, 33 Chancery Lane, London.

#### Destruction of the Irish "Tuberculosis" Van.

WE regret to learn that the "Tuberculosis Van." which was started in connection with the tuberculosis campaign of the Women's National Health Association, has been destroyed by fire at Lifford. was on tour in the north of Ireland at the time, and was on tour in the north of the last had been visited by 70,000 people. Unfortunately, now, all charts, exhibits, literature, and apparatus of various kinds have been destroyed. We understand that a fund has been established with the object of re-starting the van.

#### Conjoint Examinations in Ireland.

The following candidates have passed the Preliliminary Examinations of the Royal College of Physicians and the Royal College of Surgeons, March, 1909:—S. J. Moore Cairns, F. F. B. Darlye, J. J. Delany, G. S. Douglas, M. Fitzgibbon, W. A. N. Fox, C. E. H. Gater, W. O'C. Hunt, W. G. Keys, W. A. Malone, W. Morrow, R. P. Weldon.

#### Trinity College, Dublin.

Trinity College, Dublin.

THE following candidates passed the Intermediate Medical Examination, Hilary Term, 1909:—Part I.—Arthur Chance, Frank Crosbie, Oswald C. S. Tandy, Gerald G. P. Beckett, Hubert G. Holdbrook and William A. Taylor (&q.), Samuel A. Lane, Ronald G. M'Entire, Leonard Shiel, James C. Kelly.

Final Medical Examination.—Part II.—Midwifery.—Thomas A. Hughes, Douglas M. Moffatt, and Cecil P. Smyly (passed on high marks), Henry R. Kenny, William P. H. Smiley, Desmond Drew, Joseph P. R. Poch, Brindley H. Moore; Wellesley R. Allen, Charles G. S. Baronsfeather, and Peter H. Lemass (&q.); Denis J. Stokes, Wallace D. Mitchell, Hugh S. Metcalfe, Joseph E. N. Ryan.

# Indian Medical Service.

THE following appointments were officially gazetted on Friday last:

Lieutenant-Colonels to be Colonels.—C. F. Willis, M.D., Nov. 14th, 1908, and W. A. Corkery, Jan. 1st,

Captains to be Majors.—J. M. Woolley, M.B.; C. A. Lane, M.D., T. B. Kelly, F.R.C.S.E.; W. H. Kenrick, C. H. Watson, E. F. E. Baines, G. O. F. Sealy, S. Anderson, M.B.; F. H. G. Hutchinson, M.B.; J. L. Marjoribanks, A. Fenton, M.B., and R. W. Knox,

Marjoribanks, A. Fenton, M.B., and R. W. Knox, M.B., Jan. 28th, 1909.
Lieutenants to be Captains.—E. J. C. McDonald and W. D. Wright, M.B., Sept. 1st, 1908, H. W. Pierpoint, F.R.C.S.; Khandu Ganpatrao Gharpurey, W. D. H. Stevenson, M.B.; H. P. Cook, M.B.; W. J. Fraser, M.B.; D. C. V. FitzGerald, R. S. Kennedy, M.B.; B. Higham, M.B.; C. A. Godson, R. H. Lee, M.B.; P. Heffernan, M.B.; H. S. Hutchison, M.B.; R. G. G. Croly, M.B.; S. T. Crump, W. B. A. K. Cullen, M.B., and J. MacGregor Skinner, M.B., Feb. 1st, 1900. Feb. 1st, 1909.

To be Senior Assistant Surgeon, with the honorary rank of Captain.—Senior Assistant Surgeon, with the honorary rank of Lieutenant, E. W. Fraser, honorary rank of Lieutenant, E.

Jan. 12th, 1909.

To be Senior Assistant Surgeon, with the honorary rank of Lieutenant.—First-Class Assistant Surgeon H. W. De Lanty, Jan. 12th, 1909.

# OF RECENT MEDICAL LITERATURE. SUMMARY ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

Differential Diagnosis and Surgical Treatment of Chronic Spinal Meningitis .- Sir Victor Horsley (Brit. Med. Journ., February 27th, 1909) uses the records of 21 cases on which he has operated in discussing chronic spinal meningitis. He states it is certainly more common than tumour of the spinal cord, though it presents the same symptoms—except certain minutiæ—and is usually diagnosed as the tumour. The condition yields to surgical treatment, when ordinary medical treatment has failed. The class of cases which the author refers to under the above name are those in which an adult person—only one case being seen below the age of puberty—begins to complain of pain and progressive loss of power in the legs, with, it may be, also slight kyphotic curvature of the spine, and developes ultimately a progressive paraplegia that runs through the ordinary course and terminates fatally. The first case treated by the writer was sent to him as compression paraplegia, following supposed caries of the spine. At the operation the theca of the cord was found to be enormously distended and filled up the lumen of the canal. opening the theca, nothing but a very considerable excess of cerebro-spinal fluid was found, and a cord that was rather shrunken. No compression was found by passing a probe 5 or 6 inches up and down the neural canal. This patient was getting worse under by passing a probe 5 or 6 inches up and down the neural canal. This patient was getting worse under antisyphilitic remedies and every other kind of drug treatment, but the progress of the disease was completely stopped by laminectomy, freely opening the theca and washing out with mercurial lotion. Some typical cases are described. A dressmaker, soon after typical cases are described. A dressmaker, soon after a severe attack of influenza six years ago, commenced to complain of pain in the right loin, worse on movement, and a feeling as if the muscles of the thigh were tightening. Later painful cramping and twitching of the right leg occurred. Ultimately the pain affected the whole of the right leg, having commenced in the right groin. This point is the most valuable among the minutiæ which serve to distinguish these cases from cases of spinal tumour, in which the pain is usually localised to one nerve root. On admission, this woman was very stout and healthy-looking, with no indication of any disease above the umbilicus. There was slight wasting and weakness of the whole of the mucation of any disease above the unbilicus. There was slight wasting and weakness of the whole of the right leg. She had relative anæsthesia of the whole of the right limb and of the right hypochondriac region, the anæsthesia being of all forms of sensation, as well as relative analgesia. The deep reflexes were diminished on both sides aspecially the right. as well as relative analgesia. The deep follows well diminished on both sides, especially the right. Superficial reflexes were diminished. There was slight dribbling after micturition. There were no trophic lesions in the skin, which is a most important point between the level of the dorest of t in these cases. On operating at the level of the dorsal segment a marked degree of spinal meningitis was found and relieved with excellent results. The author draws particular attention to the degree of unilaterality found in these cases, which unilaterality has also been verified in two autopsies. The prognosis in these cases depends on the age of the patient; if at or before middle-life, it is likely to be very good; if beyond middle life, it is likely to be very good; if beyond middle life, it is likely to be very poor. The oldest patient operated on was 60 years of age, and did not improve in the least. It was a bad case, and there was a great deal of pachymeningitis, and there was a depressing history of congenital syphilis. The author considers that the condition is probably due to syphilitic, and very likely also to gonorrhæal, infection.

Case of Carcinema of the Stemach Occurring in a in these cases. On operating at the level of the dorsal

Case of Carcinoma of the Stomach Occurring in a Boy Aged Fourteen Years.—Ness and Teacher (the Brit. Journ. of Children's Diseases, December, 1908) record a case of carcinoma of the stomach occurring in a boy, æt. 14. The patient had complained of pain in the abdomen for some time before his admission to

hospital, and had suffered from marked jaundice for about two months. Shortly after admission a distinct tumour could be felt in the abdomen, and the boy developed ascites. An exploratory abdominal secboy developed ascites. An exploratory abdominal section was done, and several tumour masses were found in the abdomen, the gall-bladder was distended, and as the tumour could not be removed an anastomosis was effected between the gall-bladder and the duodenum. The patient died about a week after the operation, and at the post-mortem examination the following condition was found in the stomach:—"In the lesser curvature, a short distance from the pylorus, there was an ulcer about three millimetres in diameter." It was approximately circular in outline, with thick edges. It appeared to be a simple chronic ulcer, but there was an unusual degree of thickening of its margins and a considerable area of the stomach wall around it was also thickened and extremely hard. White hard masses extended from the outside of this area to the liver and gall-bladder, and there were numerous small white nodules in the peritoneal coat, and the gastro-colic omentum was full of similar nodules. Masses of tumour were also found at the root of the mesentery and extending through it. On histological examination the tumour was found to be a scirrhous carcinoma, with an extreme degree of fibrosis of the stroma and atrophy of the epithelial elements. Dr. Ness has only been able to find records of 19 cases of carcinoma of the stomach occurring in

persons under the age of 20 years. K.

The Natural Cure of Cancer.—Handley (Brit. Med. Journ., March 6th, 1909) publishes a highly suggestive lecture on the manner in which the organism tends to inhibit cancerous growths, or rather on the manner in which the growth tends to its own destruction. Instead of regarding, as has been usual, the degenerative process of regarding, as has been usual, the degenerative process as a mere accident of tumour-life, he regards it as an essential part of the process. "Every aggregation of carcinoma-cells has a definite life-cycle, and, after ircreasing in size for a varying period and at a varying rate, tends spontaneously to undergo degeneration and fibrotic changes. These changes extend from the centre of the mass centrifugally to its periphery, lead to its shrinkage, and terminate in the replacement of the aggregation of cancer cells by a fibrous scar." He shows that the known process of repair in cancer is a perilymphatic fibrosis which follows rapidly on lymphatic infiltration. Where the repair keeps pace with the infiltration, atrophic scirrhus occurs, where the infiltration is more rapid, there is medullary cancer. He shows, too, that in the spread of cancer as shown by the appearance of cutaneous nodules the earlier or central nodules tend to disappear as the circle widens. Two photographs of the same patient at different stages show this very clearly as regards cutaneous nodules on the abdomen. Handley offers, too, an explanation of the disappearance of the cancercell at the middle of the cancerous growth. "The epithelial cell is an obligate parasite upon the connective tissue cell." In other words, the epithelial cell, in his opinion, draws its nutriment, not from the blood, nor evn directly from the lymph, but from the lymph through the intermediation of a connective tissue cell. There is much in normal physiology, as well as in pathology, to support this view. In a cancer it follows that when the connective tissue cells have disappeared, that when the connective tissue cells have disappeared, the cancer cells must themselves undergo degeneration. We regret that space does not permit us to give Handley's arguments in fuller detail. Like all his writings on cancer, the lecture deserves the most careful perusal.

It is proposed to present Sir Felix Semon with a testimonial from his friends and admirers on the occasion of his approaching retirement.

# NOTICES TO CORRESPONDENTS. "Se: "

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a Distinctive Signature or Initial, and to avoid the practice of signing themselves "Reader," "Subscriber," Old Subscriber," etc. Much confusion will be spared by attention to this rule.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be suthenticated with the name and address of the writer, not necessary for publication but as evidence of identity.

Mr. W. STCART-LOW.—Your cases of "Malignant Disease of the

MB. W. STCART-LOW.—Your cases of "Malignant Disease of the Naso-pharynx" are marked for early insertion.

Naso-pharynx" are marked for early inserticn.

PRIMISIS.—Read the interesting memorandum recently issued by the Medical Officer to the Local Government Board. You will there find an account of the administrative measures which may be taken by sanitary authorities with their present powers. It is especially to be noted that those authorities have power to huild sanatoriums for tuberculosis, and that, without going to that expense, they can utilise their present isolation accommodation, when not needed for zymotic diseases, for the reception of tuberculous patients for educational treatment.

Ornea—We are obliged for the newspaper cutting. The

OMEGA.—We are obliged for the newspaper cutting. The matter has been dealt with in our editorial columns.

T. R. (Taunton).—It is a curious fact, and one upon which the public may be congratulated, that sheep are hardly ever known to be tuberculous.

GENERAL PRACTITIONER (Leeds).—It has been pointed out by Hertal that one of the signs of pregnancy consists in the development of fine downy hair over the entire body, and a remarkable stimulation of the hair follicles, by which rapid growth of hair in the hairy parts of the body ensues.

RESPICE FIREM (Bristol).—No ethical question is involved in the case to which our correspondent refers.

# Meetings of the Societies, Tectures, &c.

WEDNESDAY, MARCH 518T.

MEDICAL GRADUATES COLLEGE AND POLYCLINIC (22 Chenics Street, W.C.).—4 p.m.: Mr. R. Johnson: Olinique (Surgical).

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tettenham, N.).—Clinics: 2.30 p.m.: Medical Out-patient (Dr. T. R. Whiphaim); Skin (Dr. G. N. Meachen); Out-patient (Dr. T. R. Eye (Mr. R. P. Brooks).

TRURSDAY, APRIL 18T.

SONTOEN SOCIETY (20, Hanover Square, W.).—8.15 p.m.: Mr.

H. Gardiner: The Origin, History, and Development of the

X-Ray Tube.

NORTH-EAST LONDON CLINICAL SOCIETY (Prince of Wales's Hospital, Tottenham, N.).—4.15 p.m.: Discussion on Empyema (opened by Dr. T. R. Whipham).

ROYAL COLLEGE OF PHYSICIANS OF LOSDON (Pall Mail East).—5 pm.: Prof. C. S. Sherrington: The Role of Reflex Inhibition in the Co-ordination of Muscular Action, (Oliver-Sharpey Lectures.)

MEDICAL GRABUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Sir Jonathan Hutchinson: Clinique (Surgical)

In the Co-Druinstoid of College and Polyclinic (22 Omenies Medical Graduates College and Polyclinic (22 Omenies Street, W.C.).—4 p.m.: Sir Jonathan Hutchinson: Clinique (Surgical).

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—230 p.m.: Gynecological Operations (Dr. A. E. Glies). Clinics: Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. H. W. Carson); X-Rays. 3 p.m.: Medical In-patient (Dr. G. P. Chappel).

ROYAL Society of Medicine (Larinoological Section) (20, Hanover Square, W.).—5 p.m.: Cases: Dr. J. Dundas Grant: (1) Case of Retro-bulbar Neuritis, probably attributable to Sphenoidal Disease; (2) Case of Swelling over Superior Maxilla due to Angeio-neurotic Œdema; (3) Case of Rhinitis Caseoss. Sir Felix Semon, K.C.V.O.: Additional Note on Case of Malignant Disease in Left Pyriform Sinus, shown on Nov. 6th, 1908, and Feb. 1th, 1909. Mr. Stuart-Low: Case of Thyroid Tumour at the Base of the Tongue exhibited at the last meeting, now shown After Removal, with Specimen, Microscopic Slide, and Illustrations.

NEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, Hammersmith Road, W.).—8 p.m.: Clinical Evening.

Cases.

ROYAL COLLEGE OF PHYSICIANS OF LOYDON (Pall Mall East).—

# Appointments.

BLAXLAND, A. J., M.B., B.S.Lond., Honorary Assistant Surgeon to the Norfolk and Norwich Hospital.

BUCHAN, George F., M.B., Ch.B. Glagg., D.P.H.Camb., Medical Officer of Health of the Urban District of Heaton and Inleworth, Hounslow.

CANNEY, J. R. C., M.B., B.C., L.B.C.F.Lond., M.B.C.S., House Surgeon at University College Hospital.

HEWELEY, FRANK, M.B.Durh., F.R.C.S.Eng., Honorary Ophthalmic Surgeon to the Western General Dispensary, Marylebone Boad, N.W.

HILL, Miss E. S., M.B., Ch.B. Glasg., Medical Inspectress of School Children for the Borough of Burslem.

LLOTD, D. G., M.B.C.S., L.R.C.F.Lond., Certifying Surgeon under the Factory and Workshop Act for the Newcastle Emlyn No. 2 District of the counties of Carmarthen and Pembroke.

PATERSON, A. S., M.B., Ch.B. Edin., Resident Surgical Officer at the Royal Hospital, Salford.

REESE, DAVID WILLIAM, L.R.C.P. and S.Edin., L.F.P.S.Glasg., Medical Officer of Health for the Warmley (Gloucestershire). Union.

REID DOUGLAS ARTHUR, M.D.Edin., M.R.C.S., L.S.A., Medical Officer of Health of the Borough of Tenby.
SUTHERLAND, HALLIDAY, M.D.Edin., Resident Physician to the Royal Victoria Hospital for Consumption, Edinburgh.
WALKER, E. A., M.B., Ch.B.Edin., House Physician at the Royal Hospital, Salford.

# Bacancies.

Birkenhead Union.-Resident Assistant Medical Officer. Salary,

Eirkenhead Union.—Resident Assistant Medical Officer. Salary, £120 per annum, with board, washing, and apartments. Applications to John Carter, Clerk to the Guardians, Poorlaw Offices, Conway Street, Birkenhead.

Inverness District Asylum.—Junior Assistant Physician. Salary, £100 per annum, with board, lodging, and laundry. Applications to the Medical Superintendent.

Leeds Public Dispensary.—Junior Resident Medical Officer. Salary, £100 per annum, with board and lodging. Applications to the Secretary of the Faculty, Public Dispensary, North Street, Leeds.

The Royal National Hospital for Consumption, Ventor.—Male Assistant Resident Medical Officer. Salary, £100 per annum, with board and lodging in the Hospital, and washing allowance. Applications to the Secretary, 18 Buckingham Street, Strand, London.

Lavesden Asylum.—Third Assistant Medical Officer. Salary, £100 per annum, with board, lodging, and washing. Applications to the Medical Superintendent, Leavesden Asylum, King's Langley, R.S.O., Herts.

City Hospital, Birmingham.—Resident Assistant Medical Officer. Salary, £120 per annum, with board, washing, etc. Applications to the Medical Superintendent, City Hospital, Little Bromwich, Birmingham.

Beckett Hospital, Barnsley.—House Surgeon. Salary, £100 per annum, with board and lodging. Applications to R. F. Pawsey, Hon. Secretary, Barnsley.

The Hartlepools Hospital.—House Surgeon. Salary, £100 per annum, with board washing, and lodging in the Institution. Applications to Robert Edger, Secretary, 15 Town Wall, Hartlepool

Applications to Model's August, Hartlepool.
Worcester General Infirmary.—House Physician. Salary, £100 per annum, with board, residence, and washing. Applications to William Stallard, Secretary, Worcester Chambers, Pierpoint

# Births.

GIBBS-SHITE.—On March 22nd, at Cromer House, Teddington, to Edward G, Gibbs-Smith, L.R.C.P., D.P.H., and Ethei Harvard, his wife—a son.

Harvard, his wife—a son.

Harvar,—On March 24th, at Clarence Villa, Hartfield Road, Wimbledon, the wife of Joseph Harvey, M.B., of a son.

PALIN.—On March 25th, at The Oaks, Fakenham, Norfolk, the wife of Edward W, Palin, M.A., M.B., of a daughter.

Spitta.—On March 25th, at Wimbledon, the wife of Harold Spitta, M.D., of a son.

# Marriages.

THORNTON—DUNCAY.—On March 27th, in Edinburgh Dr. P. J. Thornton, of Bacup, Lance, to Winifred, second daughter of the late Thomas Duncan, of Edinburgh.

# Beaths.

PLAILIE-SHITE.—On March 24th, at Villa Victoria, San Remo, Patrick Blaikie-Smith, M.D., late of Aberdeen.

Coller.—On March 29th, at Ashurst Lodge, Worthing, Augustus Henry Collet, M.R.C.S., in his 65th year.

GERVIS.—On March 24th, from pneumonia, Frederick Harcourt Gervis, M.D., M.R.C.S., L.R.C.P., Surgeon-Captain 19th County of London Battelion, of 1, Lyncroft Mansions, West Hampstead, aged 37.

MESQUITA.—On March 28th, at the Whife House, Northdown Avenue, Margate, S. Buena de Mesquita, M.D., B.S.Lond., M.R.C.S., L.R.C.P., in his 47th year.

WALSH.—On March 25th, at the New Hospital for Women, Euston Road, London, of pneumonia, Anna Belinda Walsh, M.B., B.S.Lond., junior assistant resident surgesn, younger daughter of Rev. Canon Walsh, D.D., St, Mary's Rectory, Donnybrock, Dublin.

Have you noticed that an injection or instillation of

# ARGYROL

(SILVER VITELLIN)

relieves the pain of local inflammation, while all other silver salts increase the pain? Moreover, scientific studies prove that Argyrol quickly destroys gonococci.

These facts explain why Argyrol is considered, the world over, a superior remedy in the treatment of gonorrhœa (injection of 10 per cent. solution every three hours) and other inflammations of the eye, throat, nose and ear (25 per cent. solution instillation or local application).

Produced by

# A. C. BARNES COMPANY

32 SNOW HILL, LONDON, E.C.

The following statement concerning

# OVOFERRIN

(IRON VITELLIN)

is a copy from the official records of the largest clinic in Germany where the remedy has been in continuous use for more than four years:

"Ovoferrin is an easily assimilable, well tolerated remedy which does not disturb digestion or cause constipation, but improves the appetite, digestion and general nutrition, and produces steady and progressive increase in the percentage of hæmoglobin and red corpuscles."

Ovoferrin is furnished by chemists, on prescription, in twelve ounce bottles. The dosage is one tablespoonful in a wine-glass of water or milk three times daily.

# A. C. BARNES COMPANY

32 SNOW HILL, LONDON, E.C.

# **PNEUMONIA**

In PNEUMONIA the inspired air should be rich in oxygen and comparatively cool, while the surface of the body, especially the thorax, should be kept warm, lest, becoming chilled, the action of the phagocytes in their battle with the pneumococci be inhibited.

# Antiphlogistine

(Inflammation's Antidote)

applied to the chest wall, front, sides and back, hot and thick stimulates the action of the phagocytes and often turns the scale in favour of recovery.

It is an acknowleged fact, as declared by a well-known medical teacher and author in his latest text-book on treatment, that "heat applied and persisted in over the entire diseased area is a most potent and physiological antagonist to those essential conditions which are directly induced by the causes of the disease, and from which all ultimate pathologic results must develop. It is profoundly stimulating, and while local heat from undue combustion is present, the applied heat stimulates the capillaries and physiologically unloads the venous capillaries. At the same time it stimulates the arterial capillaries through its influence upon the peripheries of the nerves, and secondly upon the nerve centres, to drive the accumulating tide through the engorged vessels, thus unloading them into the veins. It thus carries off the accumulating waste, brings into the capillaries a new tissue supply, and quickly remedies the harm that has been done them in the primary congestion.

"It is a most rational procedure. It is logical, it is reasonable, it is physiological and it is highly scientific. And such a course is always acceptable."

# **CROUP**

Instead of depending on an emetic tor quick action in croup, the physician will do well to apply Antiphlogistine hot and thick from ear to ear and down over the interclavicular space. The results of such treatment are usually prompt and gratifying.

Antiphlogistine hot and thick is also indicated in Bronchitis and Pleurisy

The Denver Chemical Manufacturing Co.

London

"The expedient of peptonising food is one of the most rational, scientific, and practical advances of modern medicine, and has been proved devoid of the slightest theoretical or discernible objection."

# **PANOPEPTON**

Presents the entire nutritive substance of prime lean beef and best wheat flour converted into a soluble, completely and freely assimilable form.

# **PANOPEPTON**

Is instantly and wholly assimilable and sterile.

# **PANOPEPTON**

Contains all the extractives, salts, and savory matters of the beef juice, which are of peculiar value as stimulants.

# **PANOPEPTON**

Contains all the proteids of the beef and wheat in a soluble non-coagulable form.

# **PANOPEPTON**

Is a complete food, containing the albuminoids, carbohydrates and phosphates—the flesh, fit, and bone making elements.

For an adult the usual portion should be a dessertspoonful to a tablespoonful several times a day and at bedtime.

Supplied to the Medical Profession in 6 oz. and 12 oz. bottles, at 2/2 and 3/8 each.

Specimen and Pamphlet will be forwarded on request.

Originated and Manufactured by

Agents for Europe, Asia, Africa, Australasia:

Fairchild Bros. & Foster,

New York.

Burroughs Wellcome & Co.,

London, Sidney, Cape Town.

# HOMMEL'S Hæmatogen

CONTAINS NEITHER ALCOHOL NOR ANTISEPTICS

A combination of 80 parts purified and concentrated Hæmoglobin with 20 parts chemically pure Glycerine and Aromatic Flavouring.

The best of all the existing preparations of Hæmoglobin. More efficacious than Cod-Liver Oil or the ordinary manufactured preparations of Iron. Very strengthening both for Children and Adults. An energetic Blood Former. Increases the Appetite. Aids Digestion.

- Extremely useful in Rickets, Scrofula, General Debility, Anæmia, Weak Heart, Neurasthenia, and Convalescence from illness such as Pneumonia or Influenza.
- Unsurpassed as a Strengthening Restorative in Diseases of the Lunge. Has a very agreeable taste, and is taken with the utmost relish even by Children.

FREE FROM BACTERIAL GROWTH.

These important qualities are guaranteed by using the highest permissible temperature in the process of manufacture (130° to 140° Fahr. for 24 hours). No guarantee of this description is possible for preparations made by a cold process with ether.

In prescribing, always state "HOMMEL'S" Hæmatogen as spurious imitations are offered.

ONLY SUPPLIED IN FLUID, NOT IN CAPSULES OR OTHER FORMS.

Infants - Take from Half to One Teaspoonful twice a day in milk.

Children - One or Two Dessertspoonfuls daily, either pure or mixed with any convenient liquid,

One Tablespoonful twice a day before the two principal meals.

SAMPLES AND LITERATURE, gratis and carriage paid, on application.

# There is only one Adrenalin

# —the constringent, cardiac-stimulant and bloodpressure-raising principle of the suprarenal gland.

In January, 1901, PARKE, DAVIS & CO. introduced ADRENALIN into medicine. This principle was isolated in 1900 by Dr. TAKAMINE, a member of their scientific staff, and the sole right of manufacture by his process is vested in them.

The remarkable clinical results which established the position of the suprarenal principle in medicine and surgery, were obtained by the use of Adrenalin. The great importance of this therapeutic agent has brought into the market numerous preparations offered as substitutes. The action of some of these is unreliable (see article in The Proceedings of the Royal Society of Edinburgh, 1905-6), and a writer in the British Medical Journal (1908, I., 1565) states:—"Adrenalin is undoubtedly the best form of this substance."

## PREPARATIONS.

#### Adrenalin Chloride Solution, 1:1000.

**Adrenalin Tablets** (one dissolved in 1 c.c. [16.9 minims] of sterile distilled water forms the 1:1000 solution).

Adrenalin Solution has proved invaluable in numberless conditions, e.g., hæmorrhages of every kind where it can be brought into contact with the bleeding orifices, inflammations of mucous membrane, ocular hyperæmia, keratitis, iritis, lachrymal obstruction, etc.

Intravenously, in cardiac and respiratory failure it stimulates the heart almost instantaneously. Injected into serous cavities it checks effusions; into the bladder, urethra, or vagina it subdues congestion and arrests hæmorrhage.

It is given in hæmophilia, purpura, etc.; also to arrest vomiting in chloroform anæsthesia, and to obviate syncope.

## Adrenalin Suppositories.

1:1000. Used in rectitis, hæmorrhoids, rectal hæmorrhage, anal fissure, etc.

#### Adrenalin Inhalant.

A 1:1000 solution in aromatised neutral oil containing 3% of Chloretone (antiseptic and sedative). Most effective as a spray in laryngitis, whooping cough, rhinitis, hay fever, bronchitis, asthma, and in subacute and chronic inflammations of the nose, throat, and bronchi.

#### Adrenalin Ointment.

1:1000. Ensures more prolonged local action than either the Solution or the Inhalant in coryza, rhinitis, hay fever, inflammations of the urethra, vagina, cervix uteri, etc. Often of service in eczema, anal and vulval pruritus, etc.

## Adrenalin and Chloretone Ointment.

1000 parts contain 1 part of Adrenalin and 50 parts of Chloretone whose analgesic properties are valuable in inflammatory conditions of mucous membrane accompanied by pain or irritation.

By retarding diffusion Adrenalin enhances the local effect of cocaine or eucaine, whilst it diminishes their toxicity. As means for performing "painless and bloodless" surgery and dentistry, the following "P., D. & Co." preparations have been universally approved.

"Codrenine," "A" and "B."—Respectively 2 per cent. and 1 per cent. of cocaine hydrochloride with Adrenalin chloride (1 in 15000 and 1 in 5000) in physiological sodium chloride solution preserved with Chloretone.

Adrenalin and Cocaine Tablets, "A" and "C"
(P., D. & Co.).—Respectively containing 1-300 and 1-400 grain
of Adrenalin with 1-6 and 1-3 grain of cocaine hydrochloride.

"Eudrenine."—A 1 per cent. solution of beta-eucaine hydrochloride with Adrenalin chloride (about 1 in 30000) in physiological sodium chloride solution preserved with

Adrenalin and Eucaine Tablets (P., D. & Co.).— Each contains 1-2000 grain of Adrenalin, 1-8 grain of eucaine lactate and 3-5 grain of sodium chloride.

# Notes and Comments.

A LEGAL action for damages recently brought against the mayor, com-The Responsibilities monalty and citizens of London, as of Hospitals. governors of a London hospital, opens up issues of vital importance to the medical charities of the United Kingdom. The plaintiff, a medical man, suffered from a nervous disorder, for the relief of which a surgical operation was advised. He was accordingly admitted to the wards of the hospital in question, where he underwent operation. Unfortunately during that proceeding his arms came into contact with the heating apparatus of the operating table and he was severely injured. Later, he brought an action against the hospital authorities for damages on account of the permanent injury he had sustained. The foregoing facts do not appear to have been disputed, but the defendants denied responsibility, on a ground that was upheld by Mr. Justice Grantham, who is reported to have said that, were such an action sustained it would be practically impossible to carry on the work of the medical charities. With all due deference to the judicial view, we venture to think that there are certain responsibilities connected with the discharge of public duties by hospital governors, whether assumed in the cause of charity or otherwise. The failure of treatment to effect relief or cure is a matter for which a hospital cannot be answerable, but we imagine that the mere reception of a patient implies that the governors are responsible for reasonable skill and care in the carrying out of all treatment that may be required.

Is Mr. Justice Grantham be right,

Is Mr. Justice it follows, of course, that no hospital

Grantham can be sued for damages for acci
Right? dent injury. At the hearing of the

trial he stopped the case with
the declaration, "I hold there is no case to go to
the jury. It would be a policy fatal to the good
of the country, and the injury done would be untold
if I allowed this case to go to the jury." It may
be that he was referring merely to the view that
the action, if any, should have been brought
against the surgeons, and not against the
hospital authorities. It would have been
more safisfactory, however, in many ways,
had a reasoned judgment been delivered
upon what seems to be a point of considerable importance to the safety of the large
number of our fellow countrymen who resort to
hospitals for treatment. We should imagine there
is a very great deal to be said upon the conditions
of the contract implied in the reception of patients
into the wards of a hospital. Now that the
principle of compensation for accidents is being so

universally applied, it is not easy to see why a man should have no ground for compensation for damage sustained under the circumstances that led to the claim. This particular hospital management is above suspicion, and the occurrence obviously falls within the category of pure accident. Should the case go to appeal, its legal aspects would probably secure more detailed consideration than the fortune of war has accorded them in the present trial.

Black List Patients. AT a recent meeting of the Cardiff Guardians a letter was read by one of the district medical officers which has attracted a good deal of interest and comment. This gentleman, Dr. T. F. Roche, brought to the notice

of the Board the increase in the number of the persons applying to him for parochial medical attendance. This increase, he said, was due, to some extent, at any rate, to a plan which had been adopted by some of the younger practitioners at Penarth of keeping a black list of those patients who did not pay for their medical attendance. It seems that when a patient on the list applies to a practitioner for attendance, he asks for cash down, and if that is not forthcoming the medical man declines to attend. It is said that already there are some 600 or 700 black-listed families. We confess that we are very glad to see the medical profession taking this eminently judicious and sensible method of dealing with systematic "bilkers," as it is the only one likely to be effectual, and it should be adopted by men in all districts. At the moment the results, as far as Dr. Roche is concerned, are very unfortunate, as the rejected ones all come to him, and if he makes any difficulty they go to the relieving officer and get an order for free attendance. Consequently he finds himself much burdened with work.

Our sympathies are with Dr.

Roche, and now that his complaint has been brought forward and referred to a committee, we look to see the guardians revise their method of medical relief. The black-listed people, in many cases at any rate, are well able to pay, and now that they find they can so easily obtain free medical attendance, the work falling on Dr. Roche's shoulders is very considerable. Something is evidently bad about a system under which abuse of this type can spring up, and that it should exist is an admirable example of the argument contained in Dr. McVail's report to the Royal Commission on the Poor-law, referred to in our leading article this week. If free relief is granted to the poor, it

should be the relieving officer's business to find out if the applicant is deserving and really poverty-stricken, and if not the cost should be recovered by the former on behalf of the guardians, who should hand the fees thus obtained to their medical officer. The same principle is recognised in the case of emergency medical attendance on women attended by midwives, and also in the feeding of school-children whose parents are found to be able to pay. Its adoption seems to us the right way out of such a position as that at Penarth.

It is with great regret that we learn of the tragic death of Dr. A. B. Medical Wilson, house physician to the London Hospital. In the course of Martyr. his duties last month he had to attend to a woman who had taken poison with suicidal intent, and in inserting a gag to facilitate the passage of the stomach-pump, he was bitten on the thumb, the woman struggling violently in her determination not to have her purpose foiled. The wound apparently was a comparatively slight one and soon healed, but shortly afterwards he fell ill and was discovered to be suffering from blood-poisoning, with high temperature. In spite of every care and attention he died within a week. As the coroner who held an inquest on him, remarked, his was "another life sacrificed in the interests of other people. There is no doubt that there is a great deal of generous conduct and selfsacrifice on the part of doctors." It is pleasant indeed to hear a tribute such as this borne by a layman to the unseen and unappreciated daily labours of medical men, whose risks and devotion to duty under many dangerous circumstances are so little heeded by the public. Of a truth, over the grave of this promising young colleague it may be written, "He died for others."

Doctors
and
Motoring.

THE Kingston County Bench has a name which is held in awe by a certain section of motorists, and we ourselves are fully in sympathy with the magistrates in their determina-

tion not to let their roads be made a source of terror to residents because of the thoughtless conduct of inconsiderate scorchers. Last week they still further vindicated their good sense. Mr. Stansfield Collier, who was down in Surrey, was telephoned for by his house-surgeon at St. Mary's to see a patient who was in a critical condition, and Mr. Collier motored up with all speed, telling the chauffeur to drive as quickly as possible, with due regard to safety. At Cobham he was stopped by a policeman on the Portsmouth Road and told that he was travelling twenty-nine miles an hour. Mr. Collier explained that he was proceeding to an urgent case, but was nevertheless served with a summons. The circumstances were explained to the Bench by Mr. Collier himself, who added that had he not been stopped and hindered by the policeman he believed he could have saved the patient's life. Under the circumstances the magistrates decided that it would be inexpedient to impose a fine, though they thought the police were right in bringing the case forward. We admit it is difficult to abrogate the law in favour of medical men, and we are glad the case was dismissed, but bringing such a case at a distance from London and putting a defendant to all the cost and loss of time is in itself no light penalty.

# LEADING ARTICLES.

POOR-LAW MEDICAL RELIEF.

FOLLOWING on the heels of the majority and minority Reports of the Royal Commission on the Poor-laws, there appeared last week a thoughtful report by Dr. John C. McVail, County Medical Officer for Stirlingshire and Dumbartonshire, who had been deputed by the Commission to inquire into the methods and results of the present system of administering indoor and outdoor medical relief in certain selected unions. The investigations were confined to England and Wales and took count of both rural and urban districts. In nine parts, the Report treats every side of the subject, such asinfirmaries, rural and urban, workhouses, outdoor medical relief, the popularity and unpopularity of Poor-law medical aid, and the supervision of children, together with references to provident institutions for supplying medical aid and medical inspection in the home. Very pertinently, Dr. McVail points out that Poor-law medical relief is a hiatus between public charity, as evidenced by the general hospitals, and private charity supplied by medical practitioners, and that were there not these twoprops the whole system would break down. question of medical relief for the poor is, in fact, in a state of chaos; there is no co-ordination and nosystem. Private charity, the willingness of medical men to do what they can for the sake of humanity, and the support of public hospitals-all these factors vary in different districts, and the Poor-law is the padding which fills up the gaps. We are glad indeed that this unhappy, unfair, and galling muddle is so clearly set forth in a document of this importance, and we hope that once the fact is admitted, legislators and social reformers will not rest till the scandal is removed. Another point of great importance made by Dr. McVail is that if the State, as represented by the Poor-law authority, confers benefits on individuals, it has a right to demand in return a degree of submission to its orders and requirements. The hopeless condition into which our present Poor-law system has sunk is due to the disregard of the elementary principle of the quid pro quo. The State should be willing to provide for the poor and needy, but it should enforce on its protégés reasonable conditions of discipline, with the object of preventing their becoming frequent or permanent burdens on its shoulders. In a free country it may be difficult to prevent a man with money in his pocket from getting drunk, but when his money is gone and he is the subject of delirium tremens he is taken to the infirmary. Is he to be allowed out immediately he has recovered to indulge till he again comes back with the same complaint? And is he to be allowed indefinitely to pursue the same cycle of folly and disease? Again, in the case of weak-minded girls, who resort to maternity wards whenever, through pregnancy, they are unable to follow a life of immorality, are they and their babies to become a charge on the State without that institution taking any steps to guard them from a recurrence of their vice? The infirmaries have always their quota of diseased prostitutes who are no sooner nursed through the acute stages of their trouble than they are released at their own demand to pursue their

career, speading far and wide their foul disorders. Is this to the advantage of the community, and has the State no right of interference? So much for indoor treatment of this side of the relief of the sick poor. We turn to the outdoor. Says Dr. McVail of outdoor medical attendance: It is "freely and unconditionally provided by the guardians for the drunken and immoral." While these conditions prevail, in his opinion, it is not worth while entering on any reform of the Poor-law. We need hardly say that, in the main, we are in agreement with Dr. McVail. If reform is worth undertaking (and who can doubt that it is?), the reform should be radical and complete. It is easy enough to tinker by treating symptoms; what is needed is control of the causes. A person who, through his own fault, through mental or moral disease, or through vice, becomes a charge on the State, whether represented by the present guardians or, as we all hope, by a new and more dignified body, should have treatment; but that treatment should not be merely temporary and directed to the alleviation of his immediate necessities, but of such a character that the chance of his returning to his old vicious mode of life is rendered as improbable as human effort can make it. Such a condition requires that the Poor-law authority should have strong disciplinary powers, including the right to punish and the right to detain, and, further, and perhaps more important, the duty of, and machinery for, following up delinquents and exercising a guiding and controlling influence on them. The laxity of our present system permits, nay, puts a premium on, waste, dissoluteness, and irresponsibility, and thereby stands self-condemned. This fact has been borne in upon all right-minded people who have given attention to the subject, and must be impressed upon the community generally. We wish we had space to go on to the many other interesting matters in Dr. McVail's suggestive report.

## MOTOR DUST AND MILK.

A SANITARY inspector has recently called attention to the injurious effect motor dust has upon milk, and has urged upon dairymen and milk purveyors the necessity of protecting milk from that source of contamination. While the thanks of the public are due to Mr. Henry Johnson, the gentleman in question, for his timely warning, it seems desirable, nevertheless, that some qualification should be added to his proposition. First and foremost, much depends on whether the dust raised by the motors is that of town or of country roads. In the urban areas there is a vast deal of organic matter and of pathogenic material which it is most undesirable should reach so favourable a culture medium as that afforded by milk. In rural districts, on the other hand, the proportion of organic contamination of road dust is small. Nor, again, does the dust raised by motors differ in its composition from that due to horse traffic, except as regards amount and the lessened contamination by horse-droppings, owing to the displacement of the old nidus for traction by mechanical power. In point of fact, then, the problem of motor dust and milk is much the same as that hitherto presented by ordinary dust in relation to milk, and from that point every sanitarian will readily endorse Mr. Johnson's views.

Anything that educates the community upon the relation of an important foodstuff to the public health is deserving of the utmost encouragement. Hitherto the task of bringing milk under efficient sanitary control has been curiously slow. now more than half a century since such diseases as scarlet fever and enteric fever were definitely traced to the agency of contaminated milk. Since then various specific infective maladies have been added to the list, that of tuberculosis being the latest and the most important. In spite of the comparatively long period that has elapsed since the recognition of these special dangers in relation to milk, an effective sanitary control of that article of food cannot yet be said to be in existence. Even within the last few years epidemics of milk-typhoid have been reported from various parts of the Kingdom. Indeed, were it not for the saving clause whereby the consumer can shield himself to a great extent, if not absolutely, by boiling his milk. the evils arising in connection with that article would be simply rampant. Yet there is much matter for congratulation, even in the midst of our confession of shortcomings. At the present moment the great advance is being made of bringing producer and distributor under a system of combined urban and sanitary control. Another important step has been taken in inducing rural sanitary authorities to inspect the dairy cattle in their districts. When Parliament adds the keystone of compulsory slaughter of tuberculous cattle, with compensation to owners, the great end of the extermination of human tuberculosis in the United Kingdom may be regarded as well within sight. Meanwhile, there yet remains a great deal to be done in the scientific control of town distribution. Mr. Johnson has called attention to one of the main principles in that direction, namely, the exclusion of dust, whether of vehicular or other origin. The time is ripe for dealing with this and kindred points in the light of practical sanitary knowledge, and it is to be hoped that both our central and our local sanitary authorities will before long draw up authoritative by-laws for the regulation of the conditions under which an important foodstuff is stored and distributed by the retailer.

# CURRENT TOPICS.

# A Modest Savant.

In the present days of inflated reputations and of scientific advertisement it is refreshing to hear of a modest village practitioner who, without a hospital service or laboratory, had, fourteen years ago, done work that practically compelled the members of that most exclusive of all learned societies, the Paris Academy of Medicine, to choose him as one of their number. Few contemporary writers have contributed more copiously to the literature of their profession than Dr. Liégeois, of Bainville-aux-Saules (Vosges), nor have dealt with so many difficult questions with such constant distinction. Dr. Liégeois has earned for himself no less than nineteen times the title of laureat of universities and of learned societies for memoirs submitted by him in open competitions. Amongst these may be mentioned the Bernard de Civrieux prize in 1880, on the "Rôle of the Nervous System in Diseases of the Heart."

In the following year the Faculty of Paris selected as the best his monograph on "Measles." Two years later he gained six prizes, amongst them the Prix Montyon of the Paris Faculty, and a first mention at the Académie des Sciences for a memoir of 1,700 pages on the "Neuropathology of the Heart and Respiratory Apparatus." In 1884 a memoir on the "Ætiology, Pathology and Surgical Treatment of Gangrene of the Limbs," of 500 pages, was awarded the Prix Gerdy of the Society of Surgery, and this was followed up by the Prix Montyon for the second time, "On Influenza and Whooping-Cough." In 1885 he competed for the Grand Prix Portal of the Academy of Medicine, with a memoir on "The Causes and Nature of Angina Pectoris," m which he suggested what was then an entirely original theory of the mechanism of this affectionviz., that of anæmia caused by persisting ischæmia, and determined by visceral troubles, emotions, movements or efforts. The Academy endorsed the views of the author by giving him the prize, which he again obtained the following year with an essay on "Exophthalmic Goître." Besides his prize essays Dr. Liégeois has published innumerable memoirs, monographs, volumes, and articles upon the most varied subjects, although he has always shown a certain predilection for the pathology of the heart. Notwithstanding his scientific activity, Dr. Liégeois still finds time to perform the duties of mayor of his village, of cantonal delegate, of inspector of schools and of infants, of member of the Council of Hygiene, and also to manage the charities in his district. The picture of his extraordinarily full and distinguished career is particularly inspiring to those who are called upon to labour in the obscurer paths of a varied profession like that of medicine.

# Explosive Hair-Washes.

THE use of highly inflammable or explosive ingredients in hair-washes has practically fallen into disuse in the United Kingdom. In case of accident any person responsible for such a preparation would probably have to pay a heavy penalty as the result of a civil or a criminal action. Not many years ago the tragedy of lives sacrificed to the explosive hair-wash was of comparatively frequent occurrence, for it so happens that paraffin, ether, and other substances that give off highly inflammable vapours are extremely efficient in cleansing the hair and scalp. In France a well-known actress was recently burned to death in consequence of the explosion of a lotion containing ether with which a hairdresser was washing her head. Many valuable hair lotions, needless to say, are made without the use of these dangerous volatile substances. Spirits of wine, largely used in these preparations, are comparatively safe, although the person who uses them should always be warned against approaching a lighted candle or other naked light. In spite of former disastrous experiences, however, the use of petrol for cleansing the scalp has crept in to a limited extent, although its ultimate effect on the hair is destructive.

# The Children's Charter.

THE Children's Act, 1908, which came into operation last week, deserves the nickname it has received

in the evening press-the Children's Charter-on account of its very comprehensive character. In many respects, indeed, the charter imposes restrictions rather than grants privileges, but the restrictions are for the most part wise and in the child's interests. Some will think the prohibition of tobacco-smoking by all persons under sixteen a little grandmotherly, and we must confess we do not think it necessary to give to constables and park-constables the power of searching boys for suspected tobacco. Some of the most important clauses of the Act deal with the inspection of and protection of children at nurse. Among other things, it is forbidden for those who nurse children for reward to effect policies of insurance on their lives, and it is rendered penal for insurance companies to issue such policies. "Overlying" of children, if the person in bed with the child has gone to bed under the influence of drink, is rendered an indictable offence, punishable by a fine of £100, or imprisonment for two years. The giving of alcoholic drink to a child under five years of age is prohibited under penalty, except upon the order of a medical man or in case of illness. Other important sections deal with reformatories, juvenile offenders, and begging, but the points treated are too many to be enumerated here.

# Representation of Professional Interests in Parliament.

WE have often had to deplore the fact that the interests of medical men go unrepresented in Parliament, and, as a result, that legislation frequently trenches on their rights. For years the suggestion has been before the medical profession that certain members should be returned in the medical interest, whose chief duty should be to represent the views of the profession in all matters affecting either the health of the community or the interests of medical men. Nothing has so far been done to bring the suggestion into effect. We learn, however, that the members of the pharmaceutical craft are ahead of us, and, a candidate having been found, the President of the Pharmaceutical Society is appealing for support for his candidature. Pharmacists who desire a direct representative in Parliament are requested to subscribe to a guarantee to cover Mr. Glyn-Jones' election expenses, and this irrespective of party questions. It is said that Mr. Glyn-Jones, the selected candidate, will be given a constituency to fight in the Liberal interest, and pharmacy is to pay his election expenses and concentrate its influence towards his return. The experiment will be watched with great interest by medical men.

# The New Poisons Act.

The new Poisons and Pharmacy Act, which came into operation at the beginning of the present month, has various features of medico-legal interest. While it provides greater safeguards for the sale of poisons used for medical purposes, it extends the facilities for obtaining poisonous compounds used in horticulture and agriculture. Hitherto none but chemists have been allowed to sell sheep dips, weed killers, and other preparations containing arsenic and nicotine, but under the new Act county, town and borough councils may license ironmongers,

florists and others to sell such preparations in districts where the demand is not properly met. The licence is obtained in the first instance at a fee of not more than 21s., and is afterwards maintained by an annual payment of 2s. 6d. Oil and colour dealers are now required, under a penalty of £5, to label any vitriol, spirits of salt and nitric acid which they sell with the word "Poisonous," and to place on the labels their names and addresses. The list of poisons used in medicine which may be sold only by a qualified chemist is extended under the new Act, and opium has been placed in a special list of poisons, which includes morphia, cocaine, belladonna and prussic acid, which may be sold only to a person whom the chemist knows, and the purchaser is required to sign his name in the poison book, and at the same time to state the purpose for which the drug is required. In future the word "chemist" will be superseded by the word "pharmacist," and the latter title will be reserved solely for qualified individuals. In all shops where the business of chemist and druggist is carried on the qualified person in charge must display his certificate showing he is on the official roll of chemists in a conspicuous position.

## National Health in Ireland.

HER EXCELLENCY LADY ABERDEEN, who is always looking for fresh fields of disease to conquer in Ireland, delivered a very important address under the auspices of the Dublin Education Society during the past week on matters relative to the health of the growing child. In the course of the address, Her Excellency formulated a scheme for the formation of a boys' and girls' National Health Battalion, which had already gained the approval of the Commissioners of National Education. The "company card" which each boy or girl signs on joining, though perhaps containing too many different promises, still is most admirable—if only it could be carried out. However, a high ideal is always wise. The promises made by each member of the battalion are practically summed up in the first clause of the "card": "To try to practice personally the lessons on the laws of health which I receive at school," and the remaining clauses deal specifically with the items included in such a promise. There are some which, we fear, will be anathema to the members of the battalion, but there are others which might indeed be regarded, not as duties, but as rewards, for instance, "to look out for rats and kill them." If anything will compensate the average peasant boy for having to wash his teeth it will certainly be the privilege of kill-ing rats at sight! There is one curious difference between the "cards" drawn up for the boys and girls respectively. A boy is required "to wash himself daily with soap and water, to clean his teeth night and morning," whereas the girl is only told to clean her teeth night and morning, and there is no mention of washing. As medical men we must protest against the idea that a girl requires less washing than a boy. Physiologically she probably requires more, and certainly after puberty she requires more urgently the habit of washing. Further, amongst the poorer class in Ireland the boy is sometimes washed in summer, as he usually bathes whenever he gets the chance, whereas the girl seldom or never does. We therefore suggest that, in this most important particular, the rules for the girl should be altered.

# PERSONAL.

THE MEDICAL PRESS. 345

HER MAJESTY THE QUEEN, accompanied by the Empress Marie Feodorovna, paid a prolonged visit to the London Hospital on Tuesday last.

THE Prince and Princess of Wales, Prince and Princess Christian of Schleswig-Holstein, and other Royalties have given their patronage to the annual festival ball in aid of the Italian Hospital on May 10th.

PRINCESS ALEXANDER OF TECK will open the new Out-patient Department and Nuises' Home of the Royal National Orthopædic Hospital on Tuesday, April 20th. The treasurers, Lord Farquhar and Sir Richard Martin, have received a donation of £500 from the Goldsmiths' Company towards the reduction of the hilding debt of Characteristics. of the building debt of £25,000.

The Duke of Argyll will preside at the 64th anniversary clinner of the German Hospital, Dalston, which will be held at the Whitehall Rooms on Friday, May -th.

On March 24th the Prince of Wales received Sir William Church, Chairman of the Executive Committee, and Dr. E. F. Bashford, Director of the Imperial Cancer Research Fund, and considered the affairs and progress of the fund, of which he is President.

Last Monday was the 82nd birthday of Lord Lister, O.M., F.R.S., Sergeant-Surgeon in Ordinary to the King, his lordship having been born at Upton on April 5th, 1827.

Dr. Meredith Young has been appointed Medical Officer of Health for the county of Cheshire, in succession to Dr. Vacher (resigned). Dr. Young was Medical Officer for the metropolitan borough of St. Marylebone.

A FESTIVAL dinner in aid of the funds of the East London Hospital for Children, Shadwell, E., will be held at the Ritz Hotel on Wednesday. April 28th. Field-Marshal Lord Grenfell will preside.

The Gilchrist Studentship for Women has been awarded by the Senate of University of London to Miss Enid Margaret Walters. M.B., B.S. The Studentship is of £100, for one year, and is open to graduates in Honours of the London University.

In aid of the Queen Alexandia Sanatorium at Davos a matinée will be given on Tuesday, May 11th, at Drury Lane Theatre. Mr. Arthur Collins has lent the theatre, and many well-known dramatic and variety artistes have offered their services.

THE late Rev. Walter Howse, M.A., of King's College, London, has left the residue of his property to Guy's Hospital, London, in augmentat on of its endowment. It is estimated that the bequest to Guy's Hospital will amount to about £25,000.

We are glad to learn that Dr. Squire Sprigge, who has been chief of the editorial staff of our contemporary, the Lancet, has been formally appointed editor of that journal, and we beg to offer him our congratulations on his well-earned promotion.

In the Board-room of the Westminster Hospital on April 1st a presentation was made to Sir William Allchin, Vice-President and Consulting Physician to the hospital. The presentation took the form of Sir William's portrait in oils, painted by Sir Luke Fildes, R.A. All the medical staff of the hospital and many of the past students have contributed. Sir John of the past students have contributed. Sir John Wolfe Barry, Chairman of the House Committee, who presided, mentioned that Sir William was connected with the Westminster Hospital as medical registrar in 1871, assistant physician in 1874, physician in 1877, and consulting physician and vice-president in 1905.

# A CLINICAL LECTURE

ON

# DUODENAL ULCER: ITS DIAGNOSIS AND SURGICAL TREATMENT. (a)

By JAMES SHERREN, F.R.C.S.

Assistant Surgeon to the London Hospital, Surgeon to the Poplar Hospital for Accidents.

I HAVE recently had under my care several cases of ulcer of the duodenum presenting symptoms so puzzling that a definite diagnosis was impossible before operation. This led me to review the notes of all the cases of duodenal ulcer which have been under my care, in which the diagnosis was established by operation, and also all the cases of gastric ulcer diagnosed in the same way, to see if the impression I had formed was the correct one—that although a definite diagnosis is possible in most cases, in some an accurate diagnosis cannot be made. I have only used for this purpose those cases in which the ulcer of the stomach or duodenum could be demonstrated even to an onlooker, cases in which the ulcer had led to signs, both visible and palpable.

The surgery of duodenal ulcer is of recent date. We

owe much of our knowledge to the work of Mayo Robson, Moynihan, and the Mayos.

Considerable difference of opinion has existed, and still exists, with regard to the possibility of diagnosing the exact location of a peptic ulcer-whether in the stomach or the duodenum.

In the second edition of "Osler's Medicine" (1895) the following occurs:—"Can the gastric and duodenal ulcer be distinguished clinically?.... In the vast majority of cases they cannot be separated during life as the symptoms produced are identical."

Twelve years later Moynihan writes: "The symptoms of duodenal ulcer are, in the great majority of cases, sufficient to enable a diagnosis to be made."

Again, the death-rate following operation for the perforation of a duodenal ulcer is, in my experience, much greater than that of perforating gastric ulcer. These reasons have led me to take up a subject about which so much has been written of late years, but in which great room for improvement exists in the early diagnosis and treatment of the cases, particularly

when perforation has occurred.

Duodenal ulcer was, only a few years ago, looked upon as a rare condition when compared with gastric ulcer. The reasons for this are plain: Firstly, the possibility of exact diagnosis which has resulted from the extension of surgical treatment in disease of the stomach and duodenum, cases which were formerly considered to be gastric ulcer, or acid dyspepsia, now falling into their right group. Secondly, the appreciation of the exact limit between the stomach and duodenum, as W. J. Mayo has pointed out, this is marked by two veins which pass one from the superior and one from the inferior margins of the pylorus and form an almost complete venous ring, marking the pyloric orifice. This landmark can be defined in the majority of cases. As 95 per cent. of all duodenal ulcers, according to the same authority, extend to within three-quarters of an inch of the pylorus, this exact localisation is necessary. It may be asked what is the importance of these facts. Deaver and Ashurst state: "This fine distinction between gastric and duodenal ulcers is of more theoretical than practical importance, since ulcers of the first part of the duodenum so closely resemble those of the stomach in their clinical pathology, symptomatology and indications for treatment that a differentiation is rarely important." With regard to much of this statement I am not in accord, by far the greater number of cases of duodenal ulcer have symptoms which differ entirely from those given by chronic gastric ulcer, and I hold with most surgeons that the indications for

treatment are not identical. To look upon the subject in this light is unwise. Every addition to our surgical knowledge is of value and exact diagnosis should. be made where possible.

W. J. Mayo found that 60 per cent. of peptic ulcers were situated in the duodenum, Robson has given the figures as 1 to 2, with these my figures agree, 24 duodenal, 47 gastric; Osler and McRae give a higher proportion, 1 to 1. All are agreed that the condition proportion, I to I. All are agreed that the condition is much more common in men than in women. The figures given by different authorities vary somewhat, thus Moynihan found it twice as often in men as in women; the Mayos, 73 per cent. of men; Mayor Robson, 86 per cent. males; Seymour Taylor, 72 per cent. males. In my 24 cases, 22 were males. The same difference is shown in the sex incidence of perforating gastric and duodenal ulcers. During the past ten years 174 cases of perforated peptic ulcer have been treated at the London Hospital, 132 gastric, 42 duodenal, of the former 88 were male, 44 female,

of the latter 38 were male.

Duodenal ulcer may be met with at any age, but is most common about 35—40, of my series of cases the youngest was 19, the oldest 56, but the condition has been recorded in infancy. Oppenheimer collected 15 cases in children in whom melæna was the chief symptom.

According to the symptoms, it is possible to divide duodenal ulcers into four groups.

- 1. Those in which the symptoms which bring the patient under medical care are due to perforation. In many, this is the very first symptom noticed.
- 2. Those in which a definite diagnosis may be made. 3. Those in which the diagnosis of a peptic ulcer of stomach or duodenum may be made, but the symptoms are not clear as to which it is.
- 4. Those in which the diagnosis is not possible until operation.
- r. Perforation of a duodenal ulcer is one of the most serious of those surgical diseases which are amenable to treatment if diagnosed and operated upon early. These cases are often tragic in their suddenness. A man in the prime of life is suddenly seized with acute abdominal symptoms; if, as is sometimes the case, these are considered due to "liver," or "biliousness," and are lightly looked upon, a fatal result is almost certain.

In many instances, nothing indicative of the presence of an ulcer can be elicited from the past history, in only four out of the eleven upon whom I operated could I obtain a history of past dyspepsia or abdominal trouble, and in none of these was it severe. One had had "an attack of pain after food and the severe of th vomiting, lasting a few days, a year ago, but had been quite well since; "another, a very alcoholic subject, had suffered from "indigestion for five or six months, with nomities of the property of the prope months, with vomiting after meals;" in yet another there had been "pain after food, but no vomiting, for three years;" in this case there was a chronic ulcer.

Judging from the appearance and feel of the ulcers,

as discovered at operation or examined after death, all except three were chronic, although only four of the eight had produced symptoms during life until perforation occurred, and in the cases in which symptoms were produced they were not severe enough to lead to medical aid being sought in three cases; had they, it is quite probable that a diagnosis could have been made.

According to the character of the symptoms these

<sup>(</sup>a) Delivered at the Medical Graduates' College and Polyelinic.

-cases fall into two groups—(1) those in which the diagnosis of a perforated peptic ulcer is possible; (2) those in which the first symptoms which bring the patient under observation resemble those of appendicitis, or are produced by subphrenic abscess; in many of this second group the onset is gradual.

The following is a typical example of the first group:—A. G., æt. 39, was admitted to the London Hospital, June 3rd, 1906, six hours after a meal of tea and cake. Two hours after the meal he was seized with violent epigastric pain and vomiting. I saw him five hours after the onset of symptoms. There was There was

no history of previous gastric trouble of any kind.

His face was pale and drawn; the whole abdomen
was slightly retracted and was rigid, there was no superficial tenderness, but slight general deep tenderness, most marked in the epigastric region. pulse was 66, and his temperature 97°. It was obvious that he was suffering from a perforative lesion in the upper abdomen. From the location of the pain at the onset to the epigastrium, I concluded that it was stomach or duodenum, the age and sex of the patient pointed to the duodenum as the probable seat of the perforation.

I operated at once and opened the abdomen through the right rectus muscle, and found free gas in the peritoneal cavity and fluid around the stomach. The perforation was situated in the centre of a chronic ulcer of the first part of duodenum, and was the size of a pea with clean cut edges. I invaginated the ulcer with two layers of silk stitches, wiped the free fluid gently away, and, as the case was early, the ulcer chronic and the stitches produced some constriction of the duodenum, I did a gastro-enterostomy. He made an uneventful recovery, and I saw him two

months ago perfectly well.

Fortunately, this is the more usual type of per-foration, of the eleven cases seven fell into this group, and were diagnosed as a perforation of a peptic ulcer of stomach or duodenum. There is no reason why cases in this group should not be operated upon early if seeking medical advice soon after the onset of symptoms. The history of sudden onset of acute symptoms. The history of sudden onset of acute abdominal pain, often accompanied by vomiting in a healthy man, or in one who has suffered from dyspepsia; the rigid and retracted abdomen, without rise in pulse rate or temperature, should indicate surgical interference. It cannot be too often insisted upon that the sudden onset of acute abdominal pain in a healthy person, whether accompanied by vomiting or not, although there is no rise of pulse rate, almost always signifies a serious surgical condition, if rigidity of the abdomen exists, it is certain that it is a grave one, and that unless surgical help is sought at once it will be given too late.

It is one of the tragedies of surgical work that in some abdominal cases indications for operation are not present until it is too late to do good, some examples of perforated duodenal ulcer fall into this group. It is only by a close study of symptoms that are in many cases looked upon as slight that a diagnosis can be made before perforation has occurred. The symptoms of the perforation of a gastric ulcer are usually unmistakable, of a duodenal they are not always so; this is an additional reason why every effort should be made to diagnose the condition, and not be content with the position taken up by Ashurst

and Deaver.

As an example of perforation which may be mistaken for appendicitis, the following is instructive:

T. J., æt. 19, was admitted to the London Hospital, July 10th, 1907. Twelve hours before admission he had a sudden onset of abdominal pain; it was not very severe at first, for he worked for four hours, then it became so severe that he had to give up. The pain at first was a little above the umbilicus, but then settled in the right iliac fossa. There was no vomiting either at the onset or later.

He presented the appearance of a patient with a severe abdominal lesion. The abdomen was rigid and deeply tender, particularly in the right iliac fossa. His temperature was normal and his pulse 108. He had suffered from vague pain after food for three vears.

In this case the correct diagnosis was made, as the pain at the onset was above the umbilicus, and only later settled in the right iliac fossa, and from the history of previous dyspepsia.

I opened the abdomen through the right rectus, and found a large perforation in the centre of a chronic ulcer on the anterior surface of the first part of the ulcer on the anterior surface of the first part of the duodenum. The whole abdominal cavity was full of bile-stained fluid, with flakes of lymph. After closing the ulcer, I gently removed the fluid and drained through the right kidney pouch and suprapubically. The patient died 36 hours later. At the post-mortem examination no obvious cause for death was found, the ulcer was closed and no diffuse peritonitis was present.

As an example in which the diagnosis was not made,

the following is instructive.

A policeman, æt. 39, was admitted to the London Hospital, May 14th, 1908. He had not been feeling well for 14 days, but would have been at his work had he not had leave for the purpose of house shifting. He had had no definite symptoms, just "feeling out of sorts." He had never had any previous abdominal trouble. Two days before admission abdominal pain started very gradually; he vomited

for the first time 24 hours after its onset.

He was a powerfully-built, stout man, and when I saw him shortly after his admission to hospital he was lying comfortably in bed reading the paper. pulse and temperature were normal and his tongue clean and moist. The abdomen was not distended, but did not move well in the right iliac region, was slightly rigid here and deeply tender. I thought it to be the end of a subacute attack of appendicitis, and did not consider immediate operation necessary. had him put in Fowler's position, and stopped all feeding by the mouth, and saw him again twelve hours later. His pulse and temperature were unchanged, but the abdomen had become a little distended and the rigidity and tenderness were more marked. I operated immediately and opened the abdomen through the lower part of the right rectus muscle. Odourless fluid with large flakes of lymph came out, at once suggesting the correct diagnosis. After much difficulty I found the perforation in the centre of a chronic ulcer at the right and anterior part of the second portion of the duodenum. I closed it with difficulty, grafted a portion of omentum over it, and drained through the right kidney pouch, iliac fossa, and above the pubes. He died the next day. We were not allowed a post-mortem examination.

In this case the diagnosis was impossible, although duodenal ulcer was discussed; there was no preceding dyspepsia, no epigastric pain or rigidity, and those abdominal signs which were present were in the right iliac region. The fluid had trickled down along the colon and had only later become generalised. Ont of 57 cases of perforated duodenal ulcer collected by Moynihan the diagnosis of appendicitis was made in 18.

As an example of the gradual development of a subphrenic abscess as the result of the perforation of a duodenal ulcer, the following is a good example:-

B. M., æt. 19, was admitted to the London Hospital, May 5th, 1905. The illness began eight days before admission with slight pain in the upper right abdomen and occasional vomiting, but he was able to keep at work for four days, and then the pain suddenly became acute, involved the whole abdomen, and frequent vomiting set in. When I saw him the whole abdomen was rigid and distended, his pulse was 136 and temperature 99°, face drawn, and tongue dry. I opened and drained the abdomen, without searching for the cause as his condition was desperate; he died soon after. At the post-mortem examination a chronic ulcer of the junction of the first and second parts of the duodenum was found, surrounded by adhesions; this had perforated, causing a subphrenic abscess, which had later infected the whole peritoneal cavity, probably as the result of rupture.

In many cases an exact diagnosis of the seat of the perforation cannot be made before operation, but in a large proportion, 7 out of 11

of those I have treated, it is possible to diagnose the presence of a perforative lesion in the upper abdomen, and the diagnosis could have been made within an hour of perforation, all giving the absolutely sudden onset of acute abdominal pain, etc. The diagnosis in these cases between a perforation of a gastric and a duodenal ulcer cannot be made with any certainty, nor is it a matter of importance to do so, for a perforation of duodenal ulcer can be dealt with through the same incision as a gastric. It is only necessary to diagnose the occurrence of a catastrophe in the upper abdomen. In some cases the history of previous trouble leads to the correct diagnosis being made. It is important, however, to limit the diagnosis to perforation of a gastric or duodenal ulcer, and to exclude appendicitis, if possible. It does not add to the chances of the patient to have exploratory incisions in the lower as well as the upper abdomen. The situation of the pain at the onset is of great help; it is above the umbilicus in the group cases we are now considering; the onset of pain in the large majority of cases of appendicitis is in the umbilical region; the time of onset of the symptoms may be suggestive, duodenal and gastric ulcers rarely perforate during the night, the first attack of appendicitis occurs with frequency during the night or in the early morning.

In the second group of cases no rules can be laid down, every case must be gone into minutely and due regard paid to every point elicited in the previous history. The position of the pain at the onset should be inquired for, and weight laid on the region of greatest rigidity and tenderness, remembering that in many cases this will be in the right iliac fossa. If no definite diagnosis can be arrived at, I believe that the safest plan will be to operate when in any doubt; but if it is reasonably considered safe to wait, the patient should be kept absolutely at rest and nothing given by the mouth, and, above all, no morphia.

Treatment.—No time should be lost. If the patient

has to be taken to hospital or a nursing home, he should be transported on the back with the shoulders a little raised. Nothing should be given by the mouth—this should be the first rule in the treatment of all surgical abdominal emergencies. If the pain severe one injection of morphia may be given after the diagnosis is made and operation is decided upon, and no amount of apparent improvement should delay

operation.

The abdomen should be opened at once, either in the middle line or through the right rectus muscle. As a rule, when the perforation is into the free peritoneal cavity, as soon as the peritoneum is exposed it is seen to be blown out with free gas. On opening the peritoneum free fluid is usually present. The pyloric end of the stomach should be found, and the first and second parts of the duodenum carefully examined. After finding the perforation it should be closed by invagination with two layers of silk stitches; in many cases this is difficult; an omental graft may be stitched over the site of perforation when there is doubt as to its secure closure. The stomach should then be examined for other ulcers, for cases of simultaneous perforation of gastric and duodenal ulcers have been recorded. The upper abdomen should then be gently sponged with normal saline solution, and if the whole abdomen has been soiled gentle washing out after a tube has been placed immediately above the pubes through a separate incision will be beneficial. The question of gastro-enterostomy at the time of operation will often arise. On the whole, I am in favour of it being done at a later date, but it should be carried out in early cases when closure of the perforation produces stricture of the duodenum, or the ulcer which perforates is a chronic one.

Drainage is unnecessary unless peritonitis has supervened. In early cases drainage of the right renal pouch is sufficient, in later, a tube in the pelvis is also advisable. After operation, the patient should be propped up in bed, and unless the operation has been performed within a short time of perforation, all fluid withheld by the mouth. In early cases in which the perforation was completely closed, fluids can be

started at once.

It might be supposed that when once diagnosis has been made and the abdomen opened no further difficulty would arise, yet in one case in which I diagnosed perforation of a peptic ulcer, the presence of fat necrosis of the mesentery led to further search for the perforation being abandoned. It is often considered that the presence of fat necrosis indicates disease of the pancreas, but it is, of course, obvious that the escape of its fat splitting ferment by any other means would lead to the same result. I been awake to this fact, it is likely that the life of the patient would have been saved, as treatment was adopted early. The case is worthy of record to pre-

vent a similar mistake.

H. B., at 39, was admitted to the London Hospital, May 6th, 1904. Six hours before admission he was seized with abdominal pain, which was very severe. It started in the epigastric region, and was accompanied by vomiting. There was a history of dyspepsia for five or six months before. The abdomen was retracted and rigid, and there was deep tenderness in the epigastrium. Pulse 110, temperature 96°. I thought of the possibility of acute pancreatitis, as he was a stout, alcoholic man, but I dismissed this diagnosis and considered it a case of perforated gastric ulcer. I opened the abdomen above the umbilicus, yellowish, clear fluid with flakes of lymph came out, and there was the slimy feel about the omentum, so typical of fat necrosis. There was extensive fat necrosis of the mesentery and omentum. I tore through into the lesser sac and found a similar fluid to that in the general cavity. I drained here, and as the gall-bladder was distended I drained it

He died the following day. At the post-mortem examination it was found that an ulcer of the posterior surface of the first part of the duodenum had perforated into the lesser sac, and one of the anterior and right surface of the second part, into the general cavity.

At the present time I always examine the duodenum

in cases of fat necrosis.

(To be concluded in our next.)

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by James Sherren, F.R.C.S., Assistant Surgeon to the London Hospital, Surgeon to the Poplar Hospital for Accidents. Subject: "Duodenal Ulcer, its Diagnosis and Surgical Treatment."—(Concluded).

# ORIGINAL PAPERS.

# THREE CASES OF MALIGNANT DISEASE OF THE NASO-PHARYNX

BY W. STUART-LOW, F.R.C.S. ENG., Surgeon at Central London Throat, Nose and Ear Hospital, and Lecturer on Practical Otology at the Post-Graduate College.

FOR the successful eradication of malignant disease of the naso-pharynx it is imperative to operate at the earliest possible moment after the diagnosis has been made. Even should the main object in operating be only to relieve and palliate, no hesitation or delay should take place. While every effort must be exerted to remove all diseased tissue, it is most essential to conserve the structures in the pharyngeal region in every way possible, since the comfort of the patient, after operating in this region, largely depends on being able to swallow and breathe without pain, spasm or regurgitation.

CASE I.

The first case was that of a woman, æt. 64, sent up by her doctor from Luton to my clinic at the Central London Throat, Nose and Ear Hospital. in consequence of increasing discomfort in the throat and dysphagia.

She gave a history of having felt a lump in the

throat for eighteen months, and that it had increased much in size recently. The difficulty in swallowing had only come on during the last month.

She was a woman of small stature and healthy,

thin and wiry, and of active habits.

On inspecting the pharnyx, the soft palate was seen to be stretched and to bulge forward very much, especially on the left side. The naso-pharynx and the upper half of the oro-pharynx were occupied by a growth of deep red colour and rounded surface. On palpation the palate felt tense, being stretched over a firm substance behind, and this also felt firm but resilient on pressure. The growth had in-corporated itself with the soft palate on the left side. A piece was punched out, and Dr. Wingrave gave his opinion that it was of an endotheliomatous nature.

There were no glands enlarged on either side of the neck, and but little bleeding occurred after the

piece for the pathologist was taken away.

She was admitted to the hospital at once, and operated upon the following day, as it was considered that, if promptly performed, the prognosis was not unfavourable.

As from the clinical appearance of the tumour considerable bleeding was anticipated, laryngotomy was first performed, and the anæsthetic administered through this tube, a large captive sponge

being firmly fixed in the pharynx.

The soft palate was next divided through nearly its whole length over the growth. It was found that the enlargement could be shelled out from the lateral wall of the pharnyx, but had to be dissected off from the soft palate.

The hæmorrhage was rather free, but the captive sponge effectually prevented any blood entering the larynx. Three silk stitches were inserted to bring the two halves of the soft palate together, the larvingotomy tube removed, and the incision at once closed. The only after-treatment consisted in the employment of a solution of peroxide of hydrogen to spray the pharynx frequently.

She made an uninterrupted recovery, returning home in ten days. This patient was seen a few weeks ago, and no recurrence had taken place; it is now twelve months since the removal of the

tumour.

# CASE II.

The patient, a man, æt. 35, a printer by trade, was sent to the Central London Throat, Nose and Ear Hospital by Dr. Lathbury, of Dunstable, on account of increasing deafness, especially in the right ear, nasal obstruction and intonation, recurrent nasal hæmorrhage and painful cervical swell-

He had been subject to attacks of influenza for years, but otherwise his general health had been During the last year he had felt weak and easily tired, and had experienced some difficulty in breathing and swallowing at times. He had lost the sense of smell during the last few weeks, and had suffered much from headaches, the pain starting in the mass of glands on the right side of the neck.

The nasal obstruction was of three months' duration and was getting gradually worse. The deafness was of five weeks' standing, but the nasal hæmorrhage was of recent origin. He had a large mass of soft, freely-movable glands in the posterior cervical triangle, extending forwards under the sterno-mastoid muscle. This had given rise to a considerable amount of pain for a fortnight, preventing sleep.

On the left side of the neck there existed a

smaller swelling in the anterior triangle below the angle of the jaw. On inspecting the naso-pharynx it was seen to be filled with a fleshy-like mass having an irregular surface, and on palpation a soft substance was felt occupying the whole cavity. This bled very freely on palpation. It seemed to be attached to the roof by a broad indefinable base. A piece was removed for microscopic examination, when severe hæmorrhage occurred necessitating plugging with gauze soaked in a solution of adrenalin.

His heart being weak and dilated, and his spleen and liver enlarged, it was not thought safe to give a general anæsthetic; it was therefore decided to trust to local anæsthesia-viz., an injection of a

I per cent. cocaine solution.
Two drachms of this solution having been injected over the site of the skin incisions, the large mass of glands on the left side was first excised. He stood this so well that it was determined to remove the other enlarged glands, and perform laryngotomy

also under local anæsthesia next day.

Laryngotomy having been rapidly performed and the glands on the right side excised, the pharynx was firmly plugged with a large captive sponge, and the growth in the naso-pharynx removed with forceps, bent scoops and scrapers. The bleeding was very free indeed, making it necessary to again plug the naso-pharynx with a large gauze plug soaked in adrenalin chloride solution, and to wait five minutes before resuming the scraping off of the remainder of the growth. This having been satisfactorily accomplished, the naso-pharynx was firmly packed with a long gauze plug and the end brought through the mouth and secured.

Next day this plug was removed. There was no recurrence of the bleeding, and the patient made an uninterrupted recovery, returning home in six days

from the date of the first operation.

Immediately after the last operation, and before the patient was taken from the table, he was noticed to have much ecchymosis of the lids of the right eye-a veritable black eye. This gradually disappeared, but had not quite gone when he left for home. It doubtless testified to the thoroughness of the scraping, being most likely caused by interference with the perorbital venous circulation from rupture of veins leading into the pharynx.

Dr. Wingrave reported the growth to be one of endothelial sarcoma. The case proves the value of local anæsthesia in reducing to a minimum the risks of such an operation, and the imperativeness and importance of removing such malignant

growths without hesitation or delay.

#### CASE III.

T. P., a man, æt. 45, a cleaner in the employment of the Great Northern Railway, came to the clinic complaining chiefly of deafness in the left ear of a few months' standing. He also had an occasional stuffiness in the nose, especially on the left side, and there had been some recurrent bleeding from the nose. He had not much pain.

He was a thin, emaciated-looking man, but there was nothing in his past history bearing on his present condition. He had for the last fifteen years been engaged in a most dusty occupation-

viz., sweeping out railway carriages.

There were no external appearances of note-no glandular enlargements. On examining the throat the first thing to arrest the attention was the slight movement of the palate. On inspecting the naso-pharynx, on about the middle of the posterior wall, a raised ulcerated surface was seen; this extended on to the left lateral wall, and no doubt had invaded the Eustachian tube, thus accounting for the deafness in this ear. On palpation the ulcer was found to be more extensive than it appeared, and very hard. A piece was pinched off, and Dr. Wingrave pronounced it to be epitheliomatous.

It appeared that during long hours he had for years worked in his very dusty occupation. He was a very good example of malignant disease arising

in a hypomyxomatous subject.

The writer has observed a large number of cases of malignant disease in the regions of the throat and nose, and invariably hypomyia of the mucous membrane has been present, as shown by the shrivelled turbinals, and thin, dry membranes.

The patient was taken into the hospital for rest and treatment, but an operation was not undertaken, as it was not thought possible to remove all the growth. He was therefore treated with mucin both locally, internally, and hypodermically.(a) He improved in every way, gaining in weight, eating his food well, sleeping better, and losing all his pain in the throat. The growth became much softer and ceased to increase, soon presenting a clean surface. The fætor of his breath, which had been very marked, also disappeared.

After being an in-patient for three weeks, he was again treated in the out-patient department. He continued to have this treatment for five months, and there was a steady improvement for the first three months, showing what the mucin treatment of malignant disease can be depended upon to dowiz, to relieve pain and retard the growth of the tumour for a time

The cancer, however, got out of hand during the last month, and he died in the workhouse infirmary five months after the commencement of the treatment, during the absence of the writer on his summer holiday.

## CASE OF MYASTHENIA GRAVIS.

BY W. B. WARRINGTON, M.D., F.R.C.P.,

Physician to the Northern Hospital and to the Eye and Bar Infirmary, Liverpool; Lecturer in the University of Liverpool,

[Patient shown at the Liverpool Medical Institution.]

ELIZ. S., æt. 31, with no medical antecedents of importance and in previous good health, about a year ago noticed that she became very readily latigued and was able only to walk a short distance. For the last few months difficulty in swallowing and occasionally regurgitation of fluid through the nose had troubled her, she made complaint of occasional double vision. The fatigue on any exertion has recently greatly increased and has been accompanied by breathlessness, so that just before she applied for relief she was barely able to walk without assistance.

The patient was seen to be of poor general muscular development, but one could hardly speak of any localised muscular atrophy, though the falling-in of the cheeks and the lack of expression of the face at once arrested attention. Possibly the deltoid muscles were wasted more than other muscles of the limbs.

Examination was first directed to the tongue and soft palate. The tongue was rather wasted and could be protruded only to a slight extent, and then without force, though all its movements could be performed. It presented some resemblance to the tongue of progressive muscular atrophy, but the atrophy was far less marked and no fibrillary twitchings were observed.

(a) "See "Mucous Membranes and Mucin and Mulignancy." W Steart-Low. Published by Bailliere, Tindall and Cox

The palate hung rather low in the mouth, but on phonation was raised in a normal manner; the movement gradually lessened on repetition, and finally it remained as an almost motionless veil.

The vocal cords were seen to close and open normally, but repeated attempts at phonation greatly exhausted the patient, so that this examination had to be abandoned; it could be said, however, that a sustained approximation of the cords, as in singing a high note, was impossible.

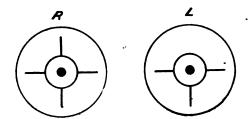

The lips could be approximated, but very little force was required to draw them apart; she could not whistle, and the explosives b and p were pro-

duced in an ill-defined manner.

On asking her to "show the teeth," it was noticed that the angles of the mouth were not drawn at all outwards, but only upwards, thus giving the characteristic appearance spoken of by Sir Wm. Gowers as the nasal snarl. The eyelids could be gently and completely closed, but the strongest endeavour of the patient could not prevent them being drawn apart by a slight effort of the observer.

The upper eyelid moved well upwards and was accompanied by the synergic contraction of the frontalis muscle; thus ptosis, an almost constant appearance in this disease, was absent. If, however, one asked the patient to repeatedly raise the eyelid, it was seen that this movement became more feeble, so that some degree of ptosis, but never to a great extent, developed. It was noticed that the contraction of the frontalis muscles ceased sometimes before the ptosis became visible

Neither eye could ever be moved to the external canthus, movement ceasing at about one-eighth of an inch from that point, and further effort was accompanied by slight wobbly movements of eyeballs. When first tested the other external eye muscles acted normally, but a repetition of endcavour to move the eyeballs in all directions soon led to obvious paresis of the upward movement of the eyes, especially of the left, which could not be moved beyond the horizontal plane. Other movements were less affected. In the stage of most exhaustion the remaining degree of mobility might be graphically represented thus by the length of the lines drawn from an inner circle indicating the circumference of the cornea.

The jaw could be opened with fair force, but only closed very feebly, so that one could with impunity permit the patient to bite one's finger.

The muscles moving the neck were very weak; at times there was the greatest difficulty in raising the head from the pillow, and when sitting or standing the head could rarely be kept erect, falling in any direction, as determined by the action of gravity for the moment. The sterno-mastoids were notably feeble in their action. The supra- and infra-hyoid muscles were fairly strong, as shown by the ascent and descent of the larynx during phonation and swallowing.

In the upper limbs the grasp of the hands was fairly strong, though after prolonged effort they became feeble. The biceps grasp and pectorales

acted well, though the power of flexion of the forearm soon tired

The biceps tired even much more readily, and the deltoid most of all; after eight endeavours the patient was no more able to abduct the arm from the side.

In the lower limbs the chief weakness seemed to be in the muscles passing from the pelvic girdle to the thigh. At one time she could just manage to raise a foot from the ground on to a chair; at another not even on to a low buffet. She could not succeed in raising herself from a chair into the erect position more than eight or ten times. Such efforts produced marked exhaustion and rapidity of breathing, in which the diaphragm took the leading part, the intercostal muscles failing soon to act well, whilst painful, but futile, efforts to use the extrinsic muscles of respiration were obvious.

So, also, to raise the body from the horizontal to the sitting posture was impossible.

The feet could be moved easily and did not show the fatigue so readily induced in the thighs. The

gait was slow and uncertain; one had constantly to beware lest the patient fell. She could, with some assistance, walk a dozen yards, and was then overcome by fatigue and breathlessness.

The reflexes of all kinds were normal and sensation undisturbed. The electric reactions showed with a number of muscles, notably the masseters, deltoids and triceps-what is called the "myasthenic reaction," i.e., after several repeated single faradic excitations, they failed to react, and similarly when one electrode was kept continuously on the muscle, the tetanus so resulting was of short duration and soon the muscle remained flaccid, this flaccidity being preceded by a few irregular flickers of the muscle fibre.

A constant characteristic observed during the patient's residence in the hospital was the variability in the degree of the various muscular weaknesses. This variability must be ranked as equal in importance to the phenomena of the rapidly-induced exhaustion; indeed, it is possible that these lastmentioned symptoms may not be obvious, whilst the extreme variability from day to day may be the striking feature.

#### REMARKS.

I do not purpose to say anything of the history or our present knowledge of this peculiar disease. It is rare; possibly, as the symptoms become better known, it will be found to be more frequent in occurrence. This and another case I saw some years ago drifted casually into the out-patient department; this had been called neurasthenia, that hysteria. Both these diagnoses were serious errors and may be disastrous, for in at least fifty per cent. this disease ends fatally by sudden respiratory failure.

If the grave organic nature of the symptoms be at first recognised, then later the observer may enter into a consideration of its exact diagnosis.

# THE X-RAY TREATMENT OF TUBERCULAR GLANDS. (a)

By A. HOWARD PIRIE, B.Sc., M.D.,

Physician in charge of the X-Ray Department of Mount Vernon Hospital for Consumption; Chief Assistant in X-Ray Department at 8t. Barthelomew's Hospital.

REPORTS have appeared in medical papers during the last five years of cases of tubercular glands which have been cured by the application of X-rays. On the other hand, some X-ray workers have had no success by means of this

(a) Paper read before the Cheisea Clinical Society, March 9th, 1909.

treatment. One has difficulty in reconciling these results, but still more difficulty in discovering the dose of X-rays that has been given to the patient. Probably the successful cases have had a sufficient dose, and the unsuccessful cases have not had a sufficient dose. People are so afraid of giving an overdose of X-rays that they go to the other extreme and do not give enough. It is only by most careful measurement of X-rays that one dare give a patient sufficient to bring about a cure.

EFFECT OF X-RAYS ON TUBERCULAR GLANDS. The effect of what I call an efficient dose of X-rays may be twofold:-

(1) It may raise the opsonic index from below normal to normal.

(2) It may kill giant cells which are forming. Dealing with the first statement, a certain amount of good work has been done in this country and in America, which has shown that after a tubercular patient has received an efficient dose of X-rays the opsonic index slowly rises.

There is not a sudden change like that which follows the injection of tuberculin. I have kept this fact in mind while treating my patients, but I have also been guided by the other theory, viz., that X-rays kill giant cells. Let me briefly give my reasons for this statement. Quickly growing cells are more easily killed by X-rays than are slowly growing cells. This is now a well-established fact, and I may remind you that the cells most easily killed in the human body are those cells which grow quickly at the root of a hair and cause the growth of the hair, the reproducing cells of the testicle (these are very easily killed, as any X-ray worker can tell you), all gland cells such as those of the skin, of the hairs, and of the thyroid, and the cells of young growing animals. Giant cells at one time in their life history were quickly growing, this has been shown by Podwyssotzki and Pirone (a), who experimented in the formation of giant cells by a method of freezing and thawing a rabbit's ear. They found that giant cells formed in three days. Any cell which grows into a giant cell in three days is a rapidly growing cell, and is therefore easily killed by X-rays. Microscopic sections of giant cells show the presence of tubercle bacilli in them. These bacilli appear to me to have made their home in the giant cell, to have filled it with their poison, and thus to be proof against the attack of leucocytes. How like they are to a larva (whose name I do not know) which invades an oak tree. The oak tree cannot throw it off, and in its effort to do so throws a protecting house around the larva, and the larva thus lives as an unwelcome guest in a gall nut. If that gall nut is destroyed the larva is set free and is devoured by a bird: so a tubercle bacillus, when unprotected by its giant cell is devoured by a leucocyte. I know that some hold a contrary view to this, but I am here fitting theory to facts, and not facts to theory. The action of X-rays is therefore to destroy the giant cell while it is forming, so that the tubercle bacilli shall have no place of defence. It is therefore imperative (1) to get the case early, while the glands are growing larger, and before the gland has begun to grow fluid; (2) to give a sufficient dose of X-rays once a week, so that the week's crop of

Archives des Sciences Biologiques," St. Petersburg, 1906. Vol XII, p. 214.

giant cells are killed before reaching maturity, and at the same time not to injure the patient's skin by X-rays.

352 THE MEDICAL PRESS.

METHOD AND DOSE OF X-RAYS USED. Keeping these theories in mind I now treat tuberculous glands with the maximum dose that the skin will stand once a week for a prolonged period. I find this dose is one-third of an epilation dose. The latter is the dose which just causes the hairs to fall out of a child's scalp. I measure this by means of Sabouraud's method, and confirm this measurement by means of my water meter. Some patients can safely have more than this dose. In order to measure one third of an epilation dose the tube should be removed to such a distance from the skin that the square of the distance in centimetres is to the square of the distance used in Sabouraud's method is as 3: 1. At the same time I protect the skin by several layers of towel, which stop ultra violet rays which are so harmful to the skin, as well as the less penetrating X-rays which would be absorbed at the surface of the skin and do

no good to the gland beneath. It reminds one

Three stimulating doses = one epilating dose. Two epilating doses = one inflammatory dose. Three epilating doses = one X-ray burn of 1st degree.

Medical men should order X-rays as they do drugs. Thus I would recommend their use as follows :-

For Ringworm—one epilating dose.

For Sycosis—one epilating dose.

For Rodent Ulcer-one epilating dose every three weeks.

For Tubercular Glands-one stimulating dose once a week.

For Acne Vulgaris—one stimulating dose every five days

For Idiopathic Keloid-one stimulating dose once a week, and so on, for other diseases which are definitely cured by means of X-rays.

To illustrate the efficiency of these doses I show you the following lantern slides. I have dealt at considerable length on the dose of X-rays, because it is all important in the efficient and successful treatment of tubercular glands by means of X-rays.

TUBERCULOUS GLANDS TREATED BY X-RAYS.

First photo. shows the condition when X-ray treatment was begun. Second photo. shows the condition after three months' treatment. Third photo. shows the condition nine months after beginning X-ray treatment.

very much of the greased paper a baker puts round a cake to keep it from burning on the surface.

Erroneous Views on X-ray Dose. One is often asked "How long do you expose the patient to the X-rays?" The question is as absurd as to ask a photographer "How long does it take to print a photograph?" The photographer might truthfully remark "Between three minutes and three months, depending on the light." So with X-rays; I have given the same dose in two and a half minutes, and in three hours by having rays of different strength. It is as important to measure the dose of X-rays as it is to measure drugs, and in large, busy hospitals it is often neglected, as it is a troublesome process. At St. Bartholomew's Hospital I have had the time and opportunity to measure carefully the dose of every patient I have treated, and the results have been very gratifying as you will see by the following cases.

For the purpose of treatment I classify X-ray doses as follows :-

X-RAY DOSE TABLE.

One stimulating dose = smallest useful X-ray unit.

# CASES.

1-6, results in various diseases of measured doses of X-rays.

7-13, results of measured doses of X-rays in cases of tubercular glands.

14, results of measured doses of X-rays in case

of lymphadenoma.

(I) Sycosis.—A man, æt. 40, with sycosis affecting the whole beard is shown in the first slide. The second slide shows the condition Treatment—one epilating dose.

(2) Rodent Ulcer.-The first slide shows a man, æt. 73, with a rodent ulcer 3" by 2" on his face. The second picture shows him cured. Treatment—

one epilating dose every three weeks.

(3) Ringworm.—First picture shows a child temporarily bald from the effect of one epilating dose of X-rays. Second photograph shows good growth of healthy hair. Treatment-one epilating dose of X-rays.

(4) Rodent Ulcer.—A similar case to (2).

(5) Keloid.—First photo. shows threei diopathic keloids. Second shows the condition cured. Treatment—one stimulating dose every week for six months, and every fortnight or three weeks for another three months.

(6) Lupus.—First photograph shows lupus affecting the nose and both cheeks. Second photograph shows the condition cured. Treatment—one stimulating dose once and sometimes twice a week, till a very slight reaction appeared, and once a week thereafter. Duration of treatment was eleven months.

Cases of Tubercular Glands.

- (7) First photograph shows a child with a mass of glands on the side of the neck. The second photograph shows the condition cured. *Treatment*—one stimulating dose once a week for nine months.
- (8) A similar case to (7). Treatment lasted fifteen months.
- (9) A similar case to (7). The glands were specially large and plentiful in this case, and the treatment lasted eighteen months.
  - (10) A similar case to (7).
- (10) A similar case to (7). Treatment three months.
  - (11) Similar case.
  - (12) Similar case.
- (13) Lymphadenoma.—First photograph shows a great mass of glands on side of boy's neck with scars of five operations for removal of glands. After each operation the glands grew quickly, and the surgeon gave up operating on them. The second photograph shows the condition nearly cured. Treatment—one stimulating dose once a week for two months, and twice a week thereafter for four months. (This case for demonstration.)

In applying X-rays it is very important to remember that the intensity of the rays varies inversely as the square of the distance at which the patient is placed, and that by using this rule it is possible to give a gland approximately the same dose as the skin covering it. Thus suppose a gland lies 2 cm.s. from the surface of the skin, and that the skin is placed 10 cm.s. from the source of X-rays. Then (supposing that none of the rays were absorbed by the skin) the intensity of the rays at the surface of the skin is to their intensity at the gland as (the squares of the distances) 144: 100—i.e., nearly in the proportion of 3:2. Now suppose the skin is removed to a distance of 100 cm.s., then the gland is 102 cm.s. distant and the skin receives 10,404 units while the gland receives 10,000 units -i.e., nearly in the proportion of 1.04 to 1, which means that the skin and the gland receive nearly the same dose.

Thus the skin will stand the action of the X-rays much better when far removed from the source of the rays, but the time of exposure has to be made much longer, in order to let the gland receive its required dose. In order to carry out this method of dosage at a distance, I have prepared a table which will be published in the Proceedings of the Royal Society of Medicine this month, but it is too technical to deal with at present.

CONCLUSION.

Tubercular glands in the neck can be successfully treated both before and after they have broken down. The best time to begin treatment is when the glands are growing larger. On two occasions I have seen a fluid gland become absorbed without opening on the surface. Usually when a gland has become fluid it opens on the surface, and heals in a month when X-ray treatment is going on. Rather than let the gland burst when it is fluid I intend, when I find a case, to aseptically aspirate the fluid and go on with X-ray treatment.

The contents are sterile, and their removal must take place before healing takes place.

The cosmetic effect when X-ray treatment is begun early is excellent, as no scar is left. The glands shrink to small, hard nodules of scar tissue, which remain under the skin, do no harm, and are not visible though they may be felt. A combination of X-ray treatment and injection of tuberculin has in the hands of M. Bergonié proved very efficacious. Tubercular glands often disappear spontaneously, and in my cases I may have done little good, but I have always been careful to do no harm. By the treatment there is no disastrous activity, and it is sometimes the height of wisdom to do nothing. The first quality required of a physician is that he shall be an honest man. Science comes after that. The evil which a medical man does not do should be counted to him for righteousness. No scar is left by this treatment, and there is no injury to nerves, which not infrequently follows an extensive operation.

#### **OPERATING THEATRES.**

ST. PETER'S HOSPITAL FOR URINARY DISEASES.
Two Prostatic Cases.—First Case.—Mr. Swin-

ORD EDWARDS operated on a man, æt. 68, who had been admitted for cystitis and enlarged prostate about a month previously. The patient on admission was thin, pale and in anything but good condition. His urine was alkaline, foul-smelling, with a low percentage of urea. Retention was complete. The prostate, as felt per rectum, was enlarged, softish, and movable, and it was evidently a good case for enucleation if the bladder could be brought into a healthy state. the bladder could be brought into a healthy state. For this purpose Mr. Edwards had opened the bladder and drained it three weeks previously. The percentage of urea having increased, and the cystitis being practically cured, it was thought a fitting time to proceed to the enucleation. It might be mentioned, Mr. Edwards said, that the supra-pubic cystotomy had been performed under local anæsthesia, the anæsthetic used being a 4 per cent. solution each of cocaine and eucaine. The operation this time was conducted under spinal anæsthesia. After draining off about a drachm of cerebro-spinal fluid, a solution of novocain and manitol was injected; an interval of ten minutes was allowed to elapse, and the supra-pubic sinus opened up sufficiently to allow the introduction of the finger comfortably into the bladder. The enucleation was completed in thirty seconds, and the prostate was delivered whole, although split down the anterior commissure, which splitting occurred in extracting the organ from the bladder through an unusually small and unyielding opening. Although the prostate stripped with the greatest ease, there was iather more bleeding attending the operation than is usual, and sensation to pain was not completely abolished, though no doubt modified. The chief pain complained of was when the sutures were being inserted after the introduction of the supra-pubic drain.

CASE 2.—This was that of a man, æt. 80. The patient was excessively stout. On him, as in the previous case, supra-pubic cystotomy had been performed a fortnight previously by Mr. Edwards for the relief of retention and for the purposes of bladder drainage, the man, on his admission to hospital, having been in a very bad condition with reference to his urinary organs. As his heart appeared to be weak, and he suffered with an old bronchial affection, it was deemed wiser to attempt enucleation under spinal anæsthesia rather than general, for which purpose a lumbar puncture was performed, as in the previous case, the patient being in the sitting posture and stooping forwards, in order to render the spinal column as convex as possible. After two vain attempts to tap the cerebro-spinal fluid, it was reached at the third essay, and after the withdrawal of a certain amount,

the same anæsthetic compound was injected as in the previous case. After a delay of about ten minutes, the suprapubic wound was enlarged upwards and downwards, and the inner fibres of the recti divided on either Bimanual enucleation of the prostate was now attempted. The left side of the prostate was stripped by the right index finger, whilst considerable pressure upwards was effected by two fingers of the left hand inserted into the rectum. It was now found quite impossible, owing to the depth of the prostate from the abdominal wall, to reach the centre limits of the gland through the limited incision which had been made, although it allowed the introduction of two fingers. About this time the patient became somewhat faint, and Mr. Edwards was debating whether he would stand a larger exposure of the bladder, allowing sufficient ancision to introduce the hand, when the patient's pulse ceased and respiration became very feeble. Further respiration became very record. Further repetative measures were desisted from, and artificial respiration was at once carried out, combined with injection of hot brandy and water into the rectum, and the subcutaneous administration of atropine. After about a quarter of an hour the patient's condition improved, so that the wound was sewn up after the insertion of a supra-pubic drain and thorough bladder irrigation. The patient was returned to the ward.

Mr. Edwards said it was uncertain what part lumbar at æsthesia had produced in this patient's collapse. The two cases that he had just operated upon would not give the onlooker probably a very favourable impression of this method of anæsthesia, but he would like to observe that during the past nine months he had carried out many cases of enucleation of the prostate under spinal analgesia, with complete success not only as far as freedom of pain and lack of shock to the patient were concerned, but also as far as facility in manipulation was concerned, owing to lack of muscular rigidity or spasm. This last case shows, he thought how difficult may be an enucleation in corpulent individuals, in some cases necessitating the introduction of more than one finger-nay, of the whole four-in order to strip the prostate successfully by reaching to its farthest limits. It might be noted, he remarked, that both these cases were secondary operations, and although no doubt the mortality of this operation is considerably lowered by r.ot proceeding to enucleate when the bladder is in a foul condition, the performance of a primary cystotomy renders the second operation more difficult owing to the fact that the peritoneum is often bound down, and would be liable to injury, being almost sure to be injured by anything like a free incision upwards; besides, the parts around the wound become contracted and un-

yielding.

Both these cases are doing well, but it is quite a problem whether the octogenarian will ever be in a good enough condition to warrant the extensive operation necessary for the removal of his prostate.

#### TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

MEETING HELD FRIDAY, MARCH 19TH, 1909.

Dr. E. H. TAYLOR in the Chair.

#### LATERAL PHARYNGOTOMY.

MR. P. J. DEMPSEY exhibited a case of lateral pharyngotomy, The patient had consulted him for hoarseness. He had no pain, but his voice got tired more easily than it ought, and he had a sensation of something in his throat. On examination, by merely depressing the tongue on the right side, the beginning of a small pear-shaped swelling was to be seen, corresponding almost identically to the posterior pillar of the fauces. The growth was found to extend down into the epiglottis. On palpation there was evidence of fluid, and it appeared to be a branchial cyst. The

patient, who had to use his voice in preaching, decided to have an operation. If the cyst were branchial, it would probably have diverticula in various directions, and could not be got at from the inside; he therefore thought it best to take it away from without. The operation was performed on November 26th as if it was a lateral pharyngotomy, although the pharynx was not opened. When he opened the cyst, about two tablespoonfuls of clear fluid came out. The wall of the cyst was curetted and packed with gauze, which was kept in for 48 hours, and then removed and a drainage-tube inserted. The tube was kept in about a week. No fluid came, and there were no signs of the cyst refilling. The recovery was uneventful. He had pain on swallowing after the operation, which disappeared in a few days. He had no trouble since with his voice.

The Chairman said the two main things in a case of the kind were thorough asepsis and the complete removal of the cyst wall. Both had been fully accomplished in this case.

Mr. R. H. Woods exhibited a case of

EXTIRPATION OF THE LARYNX, WITH A NEW APPARATUS FOR VOICE PRODUCTION.

The patient, a man, et. 42, had consulted him two months ago, complaining of pain in swallowing. On examination there was a large tumour, occupying the right half of the larynx and extending up to the middle line, which proved, on microscopic examination, to be a squamous carcinoma. Eight weeks ago, assisted by the Chairman, he opened the region of the carotid sheath and dissected out obviously carcinomatous glands. The glands were adherent, and a couple of inches of the internal jugular vein were excised on the right side. After a preliminary tracheotomy the larynx was opened, and as there was little chance of a hemilaryngotomy curing the case, the whole larynx was extirpated. The trachea was sutured to the skin, and the sac of the pharynx completely cut off from communication with the respiratory tract. In order to enable the patient to speak, it occurred to him that he might be able to convert the sound made by a reed into speech. Accordingly, he fixed a reed in a tube. By putting it into the nose and dropping it over the soft palate, and by putting the other end into the trachea he was able to blow and make the reed vibrate. A valve was used to take in the air, and when he had his chest full he put his finger to the end, and the air was pressed into the tube. Mr. Woods then inserted the instrument, and the patient, after a salutation to the section, counted from one to ten.
Mr. DEMPSEY said the case showed the results that

Mr. Dempsey said the case showed the results that could be obtained in laryngectomies when the pharynx was cut off from the respiratory tract. The real success of such a case was due to the avoidance of the danger of pneumonia, which killed nine out of ten patients formerly. Professor Gluck had performed at complete laryngectomies in the past year or two, and had not had a single death. It was too soon, however, to judge of the question of recurrence.

to judge of the question of recurrence.

Mr. W. L. Murrhy suggested the trying of a smaller tube.

The CHAIRMAN said he was much struck with the comparative ease with which Mr. Woods was able to close the pharyngeal tube.

The Secretary inquired as to the effect of the operation on the man's hope of life. Horses which were tracheotomised improved for a time, but after a while went rapidly to the bad.

Mr. Stokes asked if the patient could cough.

Mr. Woods, in reply, said there was no trouble in getting a pharyngeal wall; even after the larynx was taken away there was plenty of wall to complete a very good tube. Before doing the extirpation he thought it wise to give the patient an anti-streptococcus vaccine so as to raise his opsonic index, and his temperature only rose to 100° for two days, and then fell to normal. This was, under the circumstances, remarkable, and he thought some of the credit was due to the preliminary vaccination. The tube was sufficiently small to pass through the nose, and a smaller one would require a smaller reed, which would give less power to the voice. He had had a case of

tracheotomy about 15 years ago, and the man was in the best of health though still wearing a tube. man before them could make a respiratory effort capable of clearing off any secretion in his windpipe. He was fed after the operation by a tube through his nose. This was kept until he was able to swallow, about ten days afterwards.

Mr. W. L. MURPHY exhibited a rhinolith removed from a woman. It was wedged underneath the in-ferior turbinal, and was easy to get out. The dis-charge ceased immediately. The composition of the rhinolith was calcium carbonate and phosphate, with some organic substance resembling cellulose.

The Secretary said he did not see the exact origin of a rhinolith where there was no nucleus of a foreign body, or that any small body, such as a piece of mucus, should remain in the nose such a long time as to make a nucleus.

Mr. E. T. TAYLOR exhibited an

ECTOPIC HYDRONEPHROTIC KIDNEY

removed from a young woman about a fortnight ago. The clinical symptoms were strongly indicative of appendicitis. On palpation over her right iliac fossa he was able to determine deep fluctuation, and as she appeared to be very ill he decided to operate that evening, and to cut down over the fluctuating area with local anæsthesia. He was surprised to reach the parietal peritoneum without any evidence of pus. When he opened it, his finger passed over a surface that was bigger than a normal cæcum, and he thought it might be an ovarian cyst with a twisted pedicle. He extended the incision under chloroform, but found no pedicle. He punctured a large swelling which was fluctuating and tense, and a quantity of fluid escaped. The tissue at the edge of the opening was evidently renal. He put a tube into the kidney and drained the hydronephrosis, and after ten days removed the kidney, having a removely esticated himself that the latter was previously satisfied himself that the left kidney was healthy. The case showed that even where all typical features of appendicitis were present, they might come on a case that had nothing whatever to say to either the cæcum or appendix.

Mr. HAUGHTON said his experience of local anæsthesia was that when they got to the peritoneum they

came on extremely sensitive material.

Dr. Peacocke said he saw the girl only three days before he sent her into hospital, and he never was more positive in his life that he was dealing with appendicitis. He had great hopes, from past experience, that the girl would live a long life with only one

The Secretary (Mr. A. J. Blayney) said the frequency with which appendicitis was met with made them tend to come to the conclusion that most rightside pains were due to it; but he had seen a fair number of cases which proved to be otherwise. He had operated on somewhat similar cases as regards the pathological findings, though the symptoms were not the same. In one case there were oxalate of lime stones, which had probably excited a considerable amount of inflammatory reaction, and led to narrowing of the ureter.

Mr. TAYLOR, in reply, said the strength of novo-caine used in Berne was one tabloid dissolved in 10 c.c. of sterile water. He had used it approxi-mately at that strength, but often weaker. When getting down through the muscles towards the parietal peritoneum he always injected freely, and tried to produce ædema of the extra-peritoneal tissue. There was some pus mixed with the urine in the distended pelvis. After the operation the temperature rose to 1000, but the morning after the pain had gone, and the temperature fell to normal and remained so. The wound had practically healed, and the patient was perfectly well.

Mr. W. S. HAUGHTON exhibited a specimen of

SARCOMA OF ORBIT AND UPPER JAW from a girl, æt. about 28. For six months she had suffered from discomfort and pain in the region, and prominence of the eye-ball was noticed. She had a good deal of cedema. For a month the growth of the tumour had been rapid and the pain considerable, and the case seemed hopeless. The girl was blind. On

operating he found that the muscles were involved, and he decided to sacrifice them and the branches of the facial nerve. As a preliminary measure he ligatured the external cartoid artery, and thus controlled and limited the hæmorrhage. The roof of the antrum and the floor of the orbit were penetrated by the tumour. They had to enucleate the eyeball, and found underneath a mass of sarcomatous tissue. The septic condition following such an operation was a great trial as food particles and sloughing tissue decomposed in the mouth. He irrigated the cavity with saline fluids at frequent intervals: every half-hour for 48 hours the mouth was washed out copiously. She had very little rise of temperature, almost no decomposition in the mouth; she had practically no pain, and an uneventful convalescence.

Mr. HAUGHTON also exhibited a specimen of carcinoma removed from male breast by Halsted's method. The diagnosis had to be taken without prejudice, as it had not yet been confirmed microscopically. The patient was a farmer, at. 56. In the course of his work, one leg of a ladder, on which was a man weighing 14 st., came on his chest. Afterwards he noticed pain in the right pectoral muscle, and a few months ago a tumour appeared in the region of the nipple with a slight discharge. The tumour grew to the size of a small walnut, and was extremely hard. He had a few hard glands in the axilla. The operation was the ordinary typical one described by Halsted. It was the first cancer in the male breast he had seen, while he had seen 200 to 300 cases of cancer of the female

The CHAIRMAN said that in performing excision of the upper jaw he had performed a preliminary laryngotomy and plugged the pharynx, and found that he could proceed leisurely without the risk of blood entering the air-passages. In his experience such cases were uniformly bad as regards recurrence. When malignant growths developed outwards, metastases were slower, and prognosis was better than when they penetrated deeply.

The SECRETARY said it might be well to consider the suggestions thrown out by Coley. In cases of sarcoma he used the fluid called after his name, and he had published a number of cases which had survived for long periods without recurrence. The carcinoma was the third he had heard of in the male breast. He would give them the proportion of one to 100 in the female breast.

Mr. STOKES said he had seen two cases previous to the one before them.

Mr. HAUGHTON, in reply said he arranged the posture so that gravity would act away from the respiratory passage, which would do a good deal to prevent the inspiration of blood and septic particles.

#### I.IVERPOOL MEDICAL INSTITUTION.

SECOND CLINICAL MEETING OF THE SESSION HELD MARCH 25TH, 1909.

The President, Mr. BICKERTON, in the Chair.

DR. STOPFORD TAYLOR and Dr. R. W. MACKENNA showed the following cases:—(1) Favus affecting the thighs and legs of a steward from an emigrant ship. The scalp and other parts of the body were free. Rodent ulcer treated successfully with zinc ions. Psoriasis of the face occurring in women. Psoriasis in a man accompanied by sycosis. (5) Lupus erythematoides. (6) Syphilitic pemphigus neonatorum. (7) Dermatitis following the use of a proprietary ointment. (8) Wax casts modelled from their own cases, illustrating the cutaneous lesions of syphilis.

Dr. Logan showed a case of bi-lateral asymmetry, which he regarded as hypertrophy of the whole of the right side. The child was 15 months old, and the difference had been noticed since birth. During the last five months the right side had grown more than the left, but the head had become more symmetrical.

Dr. C. E. P. FORSYTH read a note on

THE PRESENCE OF TUBERCLE BACILLI IN THE BLOOD IN TUBERCULOSIS.

The blood of 12 patients was examined. Ten of these were undoubted cases of pulmonary tuberculosis, and in all the organism was found in the blood. The blood was drawn from a vein in the arm. In one case phagocytosis was noticed, and only in one was there any evidence of mixed infection None of the cases were rapidly progressing cases, or cases of general tuberculosis. Of the two cases in which no bacilli were found, one was probably not tubercular, and the other had physical signs of phthisis, but no bacilli in the sputum. These cases went far to confirm Rosenberger's observations for example as to the use of vaccine therapy in this disease.

Dr. HENRY CLARKE read a note on three years' experience in the use of tuberculin. His conclusions were:—(1) That tuberculin was best administered by the German intensive method, the dose being given at short intervals of one to two days, and rapidly increasing up to 1-2 c.c. of the original solution. (2) That doses given by the mouth had the same effect as when given subcutaneously. (3) That the temperature and clinical conditions were as delicate a guide to treatment as the opsonic index. (4) That new tuberculin (bacillus emulsion) was the most effective preparation. (5) That it should be prepared from human bacilli in dealing with disease produced by these bacilli. (6) To determine the variety of bacillus, he recommended Von Pirquet's cutaneous reaction. (7) He considered tuberculin a useful drug, but not a substitute for good food and fresh air.

Dr. HILL ABRAM referred to a case which he reported ten years ago, which completely recovered under treatment with tuberculin TR, subsequent experience, however, had not confirmed him in its use. He did not consider that inoculation experiments had established a vital distinction between the bovine and human varieties of tubercle bacilli. He advocated a further trial of tuberculin treatment on the German

intensive lines.

#### ULSTER MEDICAL SOCIETY.

Special Meeting Held in the Pathological Laboratory, Queen's College, Tuesday, March 30th, 1909.

The President, Mr. T. S. KIRK, in the Chair.

A LARGE number of specimens were on view from 7 till 8.30, after which hour the papers were read. Professor Milroy and Dr. J. Milroy showed microscopical preparations of the nervous system.

Professor Sinclair showed a series of surgical specimens, including many of kidney and bladder

affections.

Sir John Byers showed several ovarian tumours, including one from a patient, æt. 80, and several other gynæcological specimens.

Dr. Cecil Shaw showed a series of microscopical ections of neoplasms on the eyelids, including a very beautiful one of molluscum contagiosum.

Dr. Hicks showed three uteri successfully removed for uncontrollable hæmorrhage, showing polypoid endometritis, submucous myoma of the fundus, and carcinoma of the fundus.

Mr. Hanna showed a specimen of cancer of the larynx, and a lacerated eyeball with large foreign body.

Mr. R. J. Johnstone showed several gynæcological specimens.

Mr. Robert Campbell showed several specimens illustrating the surgery of the gall-bladder.

Professor Symmers read a paper on

ANAPHYLAXIS.

He said that a condition of hypersusceptibility to toxines had been known for some time, and had been studied lately, especially in relation to anti-diphtheritic serum. Occasionally certain unpleasant symptoms were seen after a single injection of anti-toxin, such as urticaria, cedema, or joint trouble, which came on several days after the injection. A second or third injection following in a day or two did not seem to increase the probability of such symptoms occurring; but if another dose were given after 12 days or more, it might be followed immediately by marked and even violent symptoms, such as fever, urticaria, cedema, and joint trouble. If the late dose were given after 12 days, these symptoms might be delayed for as

much as five or six days, but if the late dose were not given till the 40th day, they would be likely to appear at once. After six months, reaction still occurred, and it was not known how long the late dose might be delayed and yet produce a reaction, though it was known to be as long as five years. This condition of hyper-sensibility was apparently due to the serum, and not to the anti-toxin, and it could be produced by various other substances, as, for instance, by milk injected into the abdomen of a guinea-pig. The occurrence of this condition might explain some otherwise very puzzling phenomena occasionally observed during serum treatment, and Professor Symmers mentioned one case which occurred lately near Belfast, where a lady who had had several previous injections of antistreptococcic serum was, after an interval, given another with very alarming results. It was suggested that the serum was impure, and that some other in-fection had been introduced, but examination of the blood failed to support this theory, and probably the true explanation lay in a state of anaphylaxis having been produced. Several other cases in his experience which had shown untoward symptoms might be similarly explained.

The paper was discussed by Professor Lindsay and Drs. Gardner Robb, Houston, McKisack, and McQuitty, all of whom expressed deep interest in the views put forward in the paper. Several of the speakers had seen the cases referred to by Professor mmers, and agreed that his explanation was very

likely to be the correct one.
Dr. W. J. Wilson read a short paper on
METHODS OF ISOLATING THE TYPHOID BACILLUS.

He described the evolution of the present methods Typhoid and colon bacilli gave identical growths on nutrient agar, and the problem was to differentiate them. If lactose was added to the plate, and a little litmus, colon fermented the lactose, which turned the litmus red, but so many other organisms grew on this medium that it was not easy to find the typhoid. Conradi added a stain which prevented any but intestinal organisms growing, but it had the objection that it turned the whole plate red, and the colonies failed to show. Last year Conradi, after endless experiments, found that brilliant green and picric acid added to the medium in very minute quantities prevented the growth of any but the typhoid bacillus. Dr. Wilson had himself introduced the evaporation method, by which 4 litres of water could be evaporated under reduced pressure in 24 hours. He generally carried on the evaporation till about 10 c.c. was left, and if the water was contaminated this was found to contain large quantities of colon with only a few typhoid bacilli. In testing the method he had put 39 typhoid bacilli and 40,000 colon bacilli in 4 litres of water. In the residue the typhoid bacilli were found with ease, a result which compared favourably with the centrifugal method used by Dr. Houston, the London water expert, who added about 50 times as large a proportion of typhoid bacilli in his test. evaporation method had now been recognised as a standard method.

Dr. Wilson also read a short communication from himself and Dr. Milligan, on "Investigations on the Blood in Typhus Fever." They examined 32 cases in all, but so far their results were inconclusive, as regards finding any organism. They had satisfied themselves that Widal's test was of no use in distinguishing typhus from typhoid, as both reacted in

the same way to it.
Dr. T. Houston and Dr. S. T. IRWIN read a short paper on the

AFTER-HISTORY OF A TYPHOID CARRIER.

The history briefly was as follows:—A servant had had typhoid seven years before she came to Belfast, and from her history she seemed to have infected at least six people, of whom four were in Belfast, and under observation. All four were undoubted cases of typhoid of a mild nature. They were a man and his wife, their baby's nurse, and a hospital nurse who came to nurse them. The lady was tubercular, and had been under treatment in a sanatorium. After the attack of typhoid she did not make a very good re-covery, and tubercle was suspected. Six months later

the temperature began to rise in the evenings. urine was examined several times, and found free; then the fæces were examined, and showed typhoid infection. Two inoculations were given; the temperature came down after the first to normal, she became well, and has remained so since. Her husband made a good recovery from his attack, but the baby's nurse had never been well since her attack, suffering from headaches, and being easily tired. She has been advised to come to hospital for treatment, but has not yet done so. The hospital nurse took typhoid, and remained in poor health. On examination the bacillus of typhoid was found in abundance in her fæces. She was taken into hospital and inoculated, but the results have so far been inconclusive. The original typhoid carrier, the servant, who apparently infected the other patients, was treated in the Royal Victoria Hospital with typhoid inoculations, when her urine, which had contained the bacillus, became free, and her health good.

Dr. J. S. Dickey read a short paper on the "Surface Relations of the Apex of the Lung." The paper was based upon photographs done with a long focus lens, giving orthogonal projection of the dissections, and confirmed by measurements taken during the dis-

secting.

The meeting concluded with a vote of thanks to Professor Symmers for his hospitality to the Society, moved by Dr. Dempsey, seconded by Dr. Calwell, and passed by acclamation.

FRANCE.

Paris, April 4th, 1909.

SPOROTRICHOSIS.

Sporotrichosis, or malady of Beurmann and Gougenot, consists in subcutaneous gummata, which soften and ulcerate.

They resemble syphilis, with which they have hitherto been confounded, and so much the more as the treatment by iodides produces a speedy cure. Distinction is, however, possible, since the above-named authors made a complete study of this curious and new disease a few months ago.

From their researches they were able to divide these gummata into two clinical types—the type Dor and the

type Schenk.

The first-named is sporotrichosis, with large disseminated abscesses; the second (Schenk) resembles

the tuberculo-gumma lymphangitis of Bazin.

sporotrichosis sometimes Clinically, syphilis, sometimes tuberculosis. The gummata may not vicerate, and the persistence of the gumma, as well as the multiplicity of the abscesses, which number anywhere between five-and-thirty, and the rapid evolution of the hard gummata towards softening, facilitate the diagnosis and exclude syphilis. The distinction becomes more difficult in cases of ulceration, but here the lesions are less circular, less profound, than in syphilis. In any case, each time that no history of syphilis or tuberculosis can be discovered as to the nature of the ulceration, sporotrichosis should be suspected and treated by iodide of potassium, which acts as a specific of this malady.

BRONCHITIS AND BRONCHO-PNEUMONIA IN CHILDREN.

The treatment of bronchitis or broncho-pneumonia in children comprises three indications: render the bronchi aseptic, facilitate expectoration, and relieve the cough.

For infants, in the slight form, the patient should be kept in a warm room  $(62^\circ)$ , and the legs wrapped up in cotton wool, covered with impermeable tissue. Twice a day the thorax should be rubbed with turpentine liniment, and the room vapoured with:—

Creosote, 1 dr. Tinc. of benzoin, 2 dr. Essence of turpentine, 3 oz.

A teaspoonful to half-a-pint of boiling water.

If the case be severe, mustard poultices might be applied for two or three minutes, or just enough to redden the skin.

In children over two years of age, and more or less robust, a vomitive of hippo might be given, but not repeated, for fear of weakening the patient and pro-

voking enteritis.

In the intense form of bronchitis in infants, ipecacuanha might be prescribed in very small doses, along with balsams and antispasmodics. If diarrhea appears towards the fourth or fifth day, all treatment should be suspended, the child put on hydric treatment for a few hours, and small doses of calomel given :-

Calomel, 1 gr.

Sugar, 10 gr.
Divide into three powders. One every three hours. If the bronchitis extends to the capillaries and the lobuli—in other words, if from benign it becomes grave (broncho-pneumonia)—mustard poultices should be insisted upon, or the treatment of Preistnitz, consisting in enveloping the thorax in a compress wrung out of cold water and covered with impermeable tissue.

Diffusible stimulants are also indicated in this period :-

Acetate of ammonia, 1 dr. Syrup of ether, 3 dr. Syrup of gum, 1 oz. Water, 4 oz.

A teaspoonful every two hours.

Subcutaneous injections of camphorated oil every two or three days, says Dr. Marfau, are also indicated; up to six months a quarter of the syringe; after six months, one-half; over two years the whole syringe may be given.

In certain cases of suffocating capillary bronchitis, a mustard bath should be ordered, while septic capillary bronchitis is best treated by the cold bath, renewed three times a day.

PSORIASIS.

Cade oil, 3 oz.
Talc powder, 5 dr.
Oxide of zinc, 3 oz.
This ointment does not soil the linen, while, by reason of its adhesive properties, it renders application unnecessary for more than two days.

#### GERMANY.

Berlin, April 4th, 1000.

AT the Medizinische Gesellschaft, Hr. Bier introduced the subject of

LOCAL ANÆSTHESIA FROM THE VEINS. He described the procedure brought forward at last year's Surgical Congress, and which since that time had been subjected to many tests at operations, at which he had further elaborated the method. It was only applicable to the extremities, as it was a necessary part of the procedure that the part should be deprived of its blood. After this had been done, a part of the limb was constricted between two elastic bandages, under Schleich's anæsthesia the vein was sought (by preference the saphena vein or the cephalic) and a per cent. solution of novocain injected, so cc.m. for the arm, 80 cc.m. for the leg. For children a correspondingly smaller quantity was used. poisonous action need be feared; for greater safety, however, before the bandage was finally taken off, it might be lifted for a few seconds, and replaced; the saline solution, before final removal of the elastic bandage. Squeezing the novocain out of the wound did no harm, but it was unnecessary. The part lying between the two ligatures became anæsthetised after. 6 to 8 minutes, and in another 6 to 8 minutes motor action was abolished. The local anæsthesia was not limited to the terminals of the nerves, the nerve trunks also became completely insensible. In this way the severest operations could be performed on the extremities without the slightest pain being felt. The speaker. had performed resections of the large joints, removals of necroses, and the like many times. In 134 operations the anæsthesia had only failed in five cases.

This form of anæsthesia was indicated in operations on the extremities, but contra-indicated in the gangrenes of old age and diabetes.

After removal of the ligatures the motor paralysis disappeared at once, and the sensory after a few minutes; that was an objection, as it presupposed that the operation must be completely ended, even to the putting in of the stitches, before the blood was allowed to return to the part, the arrest of hæmorrhage must, therefore, be most exact, and even the smallest vessels be ligatured, and this was not always to be done with certainty and ease. All attempts to lengthen the period of the anæsthesia after removal of the ligatures, as by the injection of other substances, such as adrenalin, acoin, etc., had hitherto failed. The method was likely to limit the range of lumbar

At the meeting of the 17th ult., Hr. Thumin discussed the

· RELATION BETWEEN THE OVARIES AND THE

PINEAL GLAND.

In a young girl the menses failed to appear, and the symptoms of acromegaly gradually developed. During the course of this there were signs of nephritis, but these passed away; this the speaker took to be due to intoxication. Then the voice changed, it became deeper, and the singing voice was lost; by the laryngoscope the vocal cords were seen to be lengthened, a result of growth of the larynx. Whilst hypophysis tablets were being given the condition became worse, but afterwards it came to a standstill. By Röntgen illumination a tumour was seen at the hypophysis; there was atrophy of the uterus and ovaries. He considered that there was a connection between the two in the case.

Hr. Rosin made some short remarks on some

TYPHOID FEVER.

He had seen three atypical cases during the winter, such as had been described by Litten in 1879, and seen more frequently later by Ewald in Berlin, and Schlesinger in Vienna. The number of cases Schlesinger in Vienna. announced in Berlin had been rather larger than in the previous year, especially in the western part of the city. The cases were mostly amongst the better classes, and the number in hospitals was not increased. The water was not the cause, as the disease occurred in the most varied parts, with the water supply from equally varied sources. Milk and other articles of food had to be considered, caviare, perhaps, in the first line.

Hr. Fürbringer had seen similar atypical cases. The differential diagnosis between these and influenza was very difficult, and this point was not sufficiently noticed in literature.

Hr. Wolff-Eisner doubted whether cases had been more numerous than usual; neither did he think that atypical cases were more numerous in the city than in the country; in the latter parts the means of diagnosis were absent. As regarded caviare as a bearer of infection, it had been ascertained that in salted caviare the bacilli did not remain long alive, only unsalted caviare therefore came into consideration.

## AUSTRIA. |Vienna, April 4th, 1909. CHONDRO-DYSTROPHIC DWARF.

KATHOLICKY, at the Gesellschaft der Aerzte, presented a male, æt. 31, a confectioner, and measuring 120 centimetres, or 47.2 inches. The inhibition of growth seems to be confined to the extremities, which were very little bent in the lower, and not at all in the upper, the latter reaching to the trochanter tuberosity with the point of the finger. The gait is of a waddling character; intelligence good; genital organs perfect; but there is a hydocephalic cranium, measuring 50 centimetres, or 19.67 inches in circumference, set on a long, small neck, with the nose deeply depressed. The peculiarity of this case was its appearance in a family with a good history and no record where a blemish could be transmitted. He exhibited other two of the same character, but with a

different record.

Gluesner next brought forward a father, æt. 56, and son, æt. 20, who measured 101 centimetres and 108 centimetres respectively. Both of these had the characteristic symptoms of chondro-dystrophia—viz., large head, saddle nose, broad pelvis, and short extremities. There were also enlargement at the epiphyseal union, lordosis in the lumbar region, and kyphosis in the dorsal; the elder had the "main à trident" and subluxation of the femur. There was no bending of the long bones, the thyroid normal and functionally active, while the genitals were well developed and the intelligence clear, which confirmed the opinion that the cases were genuine chrondro-dystrophic in nature, that produced the dwarfish condition.

#### PHLEGMON OF PENIS.

As interesting contributions to surgery, Albrecht exhibited three cases he had successfully operated on by making free subcutaneous incisions. The first had been caused by a band tied tightly round the member. The second had been the result of phimosis, or rather para-phimosis, which led to balano-posthitis ulcerosa, and subsequently caused an abscess to form, that burst into the urethra, producing five fistulous openings, from which the urine poured. The third case was the result of an injury that occurred five years ago, with a nail that caught him, tearing the urethra from behind forwards, and damaging the organ so much in the middle that a mere bridge connected the injured part. The patient, before coming to hospital, took the scissors and cut this bridge, mutilating the organ and in-creasing the phlegmon. All of these cases were freely incised and disinfected, with the best results.

TETANY.

Spieler showed a girl, æt. 10, who had suffered for several years with recurring tetany. She had the typical cloudy lens and hypoplasia of the teeth. According to the family history, she was brought up on the breast, and learned to walk between the ninth and tenth month. She had always prominent tubera frontalis, but no special sign of rachitis. Her mind and body seemed always to develop with her age, and nothing special or unusual could be noted in her history. The tria, or Chvostek, Trousseau, and Erb's phenomena were strongly marked—i.e., pressure on the motor nerves, blood-vessels, and eccentric electric stimuli were all exalted. Gently striking the facial muscles produced easily Escherich's-Buckle phenomenon or contraction of the musculus orbicularis oris, This could be induced by striking either the upper or lower lip. If the arm were tied with a cord, or pressure on the plexus brachialis applied, the contractions were immediately induced. If the electric stimuli or galvanic irritation were applied on the left side of the head near the eye, cloudy rays could be seen running from the periphery of the lens towards the centre, while in the right lens a number of fine punctiform specks, varying in size, will be seen, as Peters has described, to radiate from the margin. In addition to these symptoms, it is interesting to note the trophic dis-turbance in the teeth, which has produced a distinct hypoplasia, particularly in the upper and lower in-cisors and pre-molars. In addition to these symptoms of the teeth and lens which the mother had observed, another important observation was made with respect to the hair, which was split up at the ends into points or trichorrhexis, apparently depending upon the disturbed trophic ectodermal surface. All these morbid changes seem to have some connection in tetany with the function of the epithelial bodies in the thyroid. The nails of the patient were remarkably healthy and perfectly normal, neither breaking, cracking, or tearing. In summing up the peculiarities of this case, he said that for eight years a chronic recurrence of tetany had been going on in this girl, which, he considered, had been directly transmitted from infancy and carried on to the puerile state, when the real distinguishing trophic disturbance in the nerves, lens, teeth and hair were physiologically developed, and, according to Pineles and Erdheim, are closely connected with the function of the epithelial bodies. Hence the disease may be correctly described as being of a parathyreopriva pathogenesis which has produced the tetany noxa.

#### HUNGARY.

Budapest, April 4th, 1909. At the recent meeting of the Hospital Association, Dr. F. Wittmann read a paper on INFANT FEEDING.

He discussed the embarrassments of infant feeding when breast milk is not available, and the unsatis-factory results of the common practice of diluting cow's milk with water in such cases. He summarised practically as follows: Cases of difficult feeding in infancy are:—(1) Those of fat indigestion; (2) those of sugar indigestion; (3) those of proteid indigestion. Each of these may occur alone, or in combination with the others. Proteid indigestion is the most common, but fat indigestion is also frequent. Each must be treated individually, the form of indigestion present must be ascertained, if possible, and appropriate measures adopted. The treatment is almost exclu-sively dietary; the fats and sugar can be regulated by varying the amounts of cream and sugar in the food. The composition of cow's milk, with its high caseinogen, must be cut down or eliminated, if need be, and the lactalbumen retained. This twofold object is attained by feeding whey, as advised by F. S. Churchill (America). In conclusion, he suggested the desirability of careful study of artificially fed infants and publication of the results.

THE RELATION OF TUBERCULOSIS TO PREGNANCY.

Dr. Popovics said that, according to the statistics, pregnancy tends to increase the susceptibility of the individual to tuberculosis. Cases occurring during the pregnant state are severe, with a marked tendency to laryngeal involvement. The pregnancy is, as a rule, not interrupted, but it is not uncommon for an advanced case of phthisis to be delivered at full term, the child dying in a few days, and the mother in a few days or weeks. Dr. Popovics has been led to consider that tuberculosis in itself predisposes pregnancy. Similar assertion has been made also by foreign doctors, as, for instance, by Malsbary, of New York. In view of the special susceptibility, pregnant women should be protected from tuberculosis, as from other infectious diseases. The habit prevalent among pregnant women of going into retirement should not be tolerated if such retirement precludes hygienic surroundings, pure air, and sunlight. Fresh air, exercise, and proper diet, combined with the use of tuberculin and creosote, constitute the essentials of treatment. The desirability of artificial interruptions of pregnancy is problematic in these cases, especially when the objective symptoms do not show progression of the disease. As far as pulmonary tuberculosis is concerned, the operation is of no especial benefit.

RADIOTHERAPY IN TRACHOMA. Dr. Pollak exhibited seven cases of trachoma and follicular conjunctivitis treated successfully by radium, the action of which he defined as "cito, tuto et jucunde." He finds a theoretical basis for the success obtained, inasmuch as it is assured by several investigators that the beneficial action of radium is due to its power to decompose the lecithin which forms a substantial element of these growths. As the granula-tions of trachoma also contain a certain percentage of this substance, the effect thereon of radium becomes intelligible. The lecturer picked out seven trachomatous cases of a most pronounced character. amount of radium used was at first 1 mg., and later 10 mg.; time of exposure, 5 to 10 minutes. The tube 10 mg.; time of exposure, 5 to 10 minutes. containing the radium was simply applied over the area treated, and slowly moved about without touching the surface. The results were really astonishing. Five of the seven eyes were entirely cured; the other two are in a fair way of becoming so. The absorption of the granules was not accompanied by any untoward The number of sittings varied from 8 to 14. Dr. Pollak firmly believes that even in cases where the granules are extensive, good results can be obtained with ladium, and that the treatment, when properly conducted, is perfectly harmless.

Dr. Révés lectured on the
TREATMENT OF EPILEPSY.

He stated that many cases of epilepsy are not benefited much by the usual bromide therapy, since, in

the place of an occasional attack of convulsions, they will now suffer from chronic bromism, which renders them absolutely unfit for any mental work. If the patient is seen after the first attack, an attempt should be made to prevent recurrence by hygienic measures alone. This is also indicated in those cases where the attacks recur not oftener than every two to three months, and frequently the proper diet, with attention to the bowels and suitable occupation and surroundings, will mean a permanent cure. Unfortunately, the bromides cannot be replaced in severe cases, and even bromipin is not always well tolerated. In certain instances, atropine, either alone or in combination with oxide of zinc, will accomplish much. The preparations of valerian will also occasionally ward off an attack, but no permanent results have attended its use.

# FROM OUR SPECIAL CORRESPONDENTS AT HOME.

#### SCOTLAND.

EDINBURGH UNIVERSITY SPRING GRADUATION CEREMONIAL.—The graduation ceremonial, which took place on April 2nd, was notable in that for the first time the Sex Faculties of the University were simultaneously represented; the granting of medical degrees in the spring-time is a novelty, depending on the recent rearrangement of the professional examinations, and is, therefore, likely to be repeated in future years. For the first time in the history of the University two ladies received the degree of Bachelor of Laws. The list of recipient of Honorary Degrees was unusually large: it included the names of Professor Crum Brown, Mr. J. M. Barrie, Mr. J. G. Bartholomew, Lord Dundas,. Sir Alfred Keogh, Professor Kronecker, and others. In introducing the recipients of the degree of LL.D., Sir Ludovic Grant described the work of each in one of his usual felicitous speeches—he paid a tribute to the catholicity of Professor Crum Brown's interests, saying that on him had fallen the mantle of the first Professor of Chemistry in the University, who was of such versatility that he was simultaneously appointed Professor of Hebrew and Chemistry. The appropriateness of the remark will be apparent to all who know Professor Crum Brown's accomplishments as an Orientalist. To Sir Alfred Keogh, Sir Ludovic paid the compliment of ascribing to his organising genius. the improved status of Army doctors and the betterment of their relations with the combatant branch of the Service, and also the arrangements which are being made whereby the Territorial forces will enjoy the services of the leading physicians and surgeons throughout the country. Professor Kronecker has just throughout the country. Professor Kronecker has just completed his 70th year, and in congratulating him Sir Ludovic Grant asked his acceptance of the degree Sir Ludovic Grant asked his acceptance of the degree as a birthday offering. After the ordinary degrees had been conferred, the new graduates were addressed by Professor Kirkpatrick, who urged that the teaching of History in the University required amplification by the foundation of Chairs of Greek and Roman History and of Constitutional History. Heales claimed for Modern Languages that they should also claimed for Modern Languages that they should once and for all receive recognition as fully equal to Latin and Greek, and spoke of the reforms needed in the Faculty of Law, whereby the B.L. degree, instead of being limited to Scottish students by the compulsory inclusion of Scots Law and Conveyancing, might become attractive to English, Indian, and Colonial students.

TREASURY COMMITTEE ON SCOTTISH UNIVERSITIES .-The committee which was promised some months ago to consider the claims of the Universities for additional State assistance has now been appointed and consists of the following members, with Lord Elginas chairman:—Miss Haldane, Sir Kenelm Digby, Principal Sir Harry Reichel, Mr. C. M. Douglas, Professor A. R. Forsyth, D.Sc., and Professor Sims Woodlead. Miss Haldane is a sister of the Missier for head. Miss Haldane is a sister of the Minister for War, and is well known in Edinburgh for her interest in educational matters. Professor Woodhead and Mr.

Douglas are connected with Edinburgh, the latter being a son of the late Dr. Halliday Douglas. Sir Harry Reichel is now Principal of Bangor University; he wrote the Moseley Commission Report on Education in 1904. Professor Forsyth is a native of Glasgow, and has been the Sadlerian Professor of Pure Mathematics since 1895.

Hon. Sydney Holland on Edinburgh Poorhouses. The Scotsman of April 1st contained a letter from the Hon. S. Holland adversely criticising the administration of the Edinburgh poorhouses, particularly as regards their hospital management. He was inspired, he says, to come and see for himself how things were done, from a study of Mrs. Sydney Webb's report (the minority report of the Poor-law Commission), and found what she alleged—impossible and intolerable as it seemed—was all true. The gist of his complaint against the Poor-house (Craiglockhart is that particularly specified) is that for an institution with over 800 inmates, 280 of whom are in the hospital, there is only one lady resident medical officer, who supervises the wards, operates when necessary, attends the confinements, performs post-mortems, and examines all persons admitted. The nursing is also inadequate; no proper sterilising apparatus is supplied to the theatre; the only other assistance afforded is that of a consulting medical officer who visits twice a week. An attack of this kind, made by a man occupying so responsible a position as Mr. Holland, cannot, of course, pass unanswered—indeed, much of his criticism appears to be justified. At the same time, it must be remembered that the class of patient admitted to the Poor law hospitals in Scotland differs consider. to the Poor-law hospitals in Scotland differs considerably from that admitted to English infirmaries. Most of the cases here are of chronic disease; sudden cases of acute illness or emergency are seldom, if ever, admitted to Craiglockhart. Again, it is certainly not uncommon for the staff of the Poor-house to obtain the assistance of a surgical specialist when serious operations have to be performed; and, as a matter of practice, the consulting medical officers visit more frequently than the statutory twice weekly. One serious part of Mr. Holland's allegation is that among the duties required of the lady medical officer is that of superintending a ward for male venereal disease. Some years ago, when women were first appointed to these posts, an arrangement was made whereby this class of case was treated only at Craiglockhart, then under the charge of a male resident surgeon. Apparently, however, with the lapse of time this arrangement was forgotten, and though the venereal cases were still drafted to Craiglockhart, a woman was appointed to the house-surgeonship. Apart from the slight resentment which Mr. Holland's rather gratuitous attack may cause, his criticisms, in so far as they are just, will doubtless do good by drawing attention to what defects exist in the management of the Poor-house hospitals. It is only right to add that Mr. Holland most amply bears witness to the efficiency of the lady medical officer—the burden on her, he considers, is not one which can fairly be borne.

#### BELFAST

BELFAST OPHTHALMIC HOSPITAL.—The annual meeting of this hospital was held last week. Mr. Frank Workman presiding. The medical staff report was read by Dr. Cecil Shaw, and spoken to by Dr. Walton Browne. It showed increased work in every department. The total number of patients seen in the extern department was 2,315, and the total number of visits paid was 7,767. An urgent appeal was made for funds to alter and enlarge the extern department at an estimated cost of about from and also for increased mated cost of about £500, and also for increased annual subscriptions. For many years the sum charged for patients sent up from country Unions for special treatment was only 7s. per week, which was quite insufficient to pay for them, and the charge has now been altered to 15s. per week, which it is understood is that paid to most Dublin hospitals where Union patients are sent. The average cost of patients in the hospital

per bed occupied is about 21s, per week.

ROYAL VICTORIA HOSPITAL.—The annual meeting of this hospital was held last week, and as in the smaller

hospital the gist of the business was an appeal for more funds, four wards being empty for want of money to maintain them at work. The treasurer said that he found that the cost per bed in the Royal Hospital came out 48 per cent. cheaper than the average of twelve principal hospitals in London, and 17 per cent. cheaper than the average of nineteen chief English and Scotch provincial hospitals. The medical staff report stated that the number of intern patients treated during the year was 1,375 medical and 1,961 surgical. There were 1,427 operations, with a mortality of 4.62 per cent. In the extern department over 30,000 new cases were treated, and 4,718 teeth were extracted. Mr. R. J. Johnstone, in moving the adoption of this report, appealed for £5,000 or £10,000 for a new X-ray department, which he suggested some wealthy person might give to them.

PUBLIC HEALTH.—During last month the death-rate in Belfast was only 20.3, as compared with 27.3 during the same period last year, while the rate from zymotic disease was only .6, as compared with 2.8. For four weeks there was not a single case of typhoid fever—probably a unique event in the history of Bel-

fast for many years past.

#### LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents, ]

#### "DOCTORS AND MIDWIVES."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The last communication from Dr. Griffith is suggestive. A few thoughts occurred to me while reading it. I think that some of our recently qualified colleagues would be eternally grateful to Dr. Griffith if he would direct them to some of these isolated spots where it would be difficult or impossible to obtain the assistance of a colleague in the event of an emergency. The difficulty of most of us is to prevent our colleagues assisting us against our wish. Personally, I should prefer to be sent for by a nurse unnecessarily, rather than when damage is done; which damage I am expected to repair, with the knowledge that I shall get the credit of having done the mischief.

Just a word about the administration of chloroform. If we allow a nurse to give an anæsthetic we are guilty of "covering." We should be more guilty morally than if we employed an unqualified assistant to perform the same duty, who had completed his curriculum, but who had not as yet passed his final. How we rejoiced when we got rid of the unqualified assistant, and yet if Dr. Griffith's dreams came true we should be merely replacing one abuse by another,

and a greater one.

Then we must remember that the operator is responsible for the anæsthetist, and in the event of a patient dying under an anæsthetic administered by a nurse, I fear that the medical man would not emerge from the inquest without censure.

I am, Sir, yours truly, S. J. Ross.

Monkhams, Bedford, April 3rd, 1909.

#### THE DECLINING BIRTH-RATE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,-Mr. Clement H. Sers seems to overlook many vital facts. The British Empire, including India. holds altogether not more than 60,000,000 of people of European blood. Our colonies, together as big as three Europes, with the finest climates on the earth's surface, and with scarcely touched, inexhaustible resources, are crying out for people. With a properly organised Imperial system of emigration they could take and absorb our normal increase for hundreds of years. If we do not fill these lands ourselves, they will in the end—an end not far off—virtually cease to be British, through swamping by alien peoples, if they are not taken by force by some more virile race. If the present decline in the birth-rate continues, we shall

presently have no surplus to send away. Mr. Sers seems to think that our present mass of wastrels and unemployables represents an irreducible minimum; it is diminishing, and will diminish yearly with greater rapidity as the nation adopts the measures of social reform which all parties in the State are now agreed upon. The number of physically unfit will diminish with improving national sanitation, with the control of tuberculosis; and the prevention of rickets, and all the minor maladies which lead to permanent unfitness of greater or less degree. Reform of the Poor-law, the Children's Bill, with improving education, and such-like measures, will improve the morale of the masses. The prime importance of social reform is accepted by statesmen, and will be worked for with increasing ardour, and there is good reason to suppose that the number of our december with that the number of our degenerates will gradually sink to a negligible quantity. Next, Mr. Sers forgets that Germany has at home 65,000,000 of people, many more millions than we have of whites in our entire Empire, and that she is increasing at the rate of a million a year. Then he forgets that France, which has carried the population question to the logical conclusion of the anti-patriotic egoist, her married citizens all refusing to make the sacrifice needed in rearing more than two children, now lies at the mercy of Germany, having only 39,000,000. Every single year for the last thirty years Germany, through her increase, has become a full army corps stronger than France. If we follow France's example, we shall be as a world power in a similar position within very few years. The French are a dying race; their wealth increases while their men decay. Their decadence is manifest in moral as well as physical phenomena; it forms the most serious as well as most interesting forms the most serious as well as most interesting study in contemporary history, an object-lesson which, it is to be hoped, may not be obscured completely by the prevailing cult of the entente cordiale.

I am, Sir, yours truly,

A STUDENT OF SOCIOLOGY.

March 31st, 1909.

\_\_\_\_\_

#### **OBITUARY.**

PROFESSOR ARTHUR GAMGEE, M.D., LL.D.ED., F.R.S., F.R.C.P.LOND. AND ED.

WE regret to announce that Professor Arthur Gamgee died in Paris on Monday, March 20th, in his 68th year. He was Emeritus Professor of Physiology in the Victoria University, and had been Assistant Physician to St. George's Hospital, London.

Elected a Fellow of the Royal Society at a very early age, his life was devoted to special research work in problems of physiological chemistry; and he held, from time to time, a number of physiological posts in the University of Edinburgh, in Owens College, and in the Royal Institution of Great Britain. He added largely to our knowledge of the chemistry of the blood and of its colouring matter; and much of his work was and of its colouring matter; and much of his work was conducted in the physiological laboratories of Germany, France, and Switzerland. Apart from a large number of papers, he will be chiefly remembered for his "Text-book of Physiological Chemistry of the Animal Body," in which much original research was incorporated, and which has been translated into French and German.

Dr. Gamgee was a fine classical scholar and a good aguist. His unexpected death was due to pneumonia, which developed after an attack of influenza.

#### JAMES HARDIE, M.D.Ed., F.R.C.S.

We regret to announce the death of Mr. James We regret to announce the death of Mr. James Hardie, of Manchester. Born at Tyinghame, in East Lothian, in 1857 he entered the University of Edinburgh as a medical student, and came under the influence of the great Syme and the still greater Lister. The opportunity of becoming a surgeon, which he much desired, came to him when he was made Surgeon to the, at that time, small Clinical Hospital for Diseases of Women and Children at Park Place, Cheetham, now the Northern Hospital. This success

was followed by his appointment as surgeon to the Manchester Township Hospital. His excellent work in these two offices prepared the way for his election to the position of Honorary Assistant Surgeon to the Manchester Royal Infirmary. This was in 1876. On the retirement of Mr. Edward Lund, in 1882, he became full Surgeon to the Institution, which position he occupied until 1901, when he became Consulting Surgeon. As a surgeon Mr. Hardie devoted himself especially to orthopædics. In such cases he was distinguished by the originality and ingenuity of his operations, and the dexterity and success with which he carried them out. For some years he was a member of the Council of the Royal College of Surgeons, a position which he filled with distinction.

#### DAVID PIERCE FOULKES, M.B., C.M.ED.

WE regret to record the death of Dr. D. P. Foulkes, of Conway, which took place at Swansea, following an attack of rheumatic fever. Some six months ago Dr. Foulkes accepted an appointment at the Swansea Hospital, where his fatal illness began, but he had not been in good health for some years. The son of Mr. Thomas Foulkes, of Conway, and formerly of Blaenau Festiniog, he took his degrees of Bachelor of Medicine and Master in Surgery at the Edinburgh University in 1893, and for some years afterwards practised at Conway.

AUGUSTUS HENRY COLLET, B.A., M.R.C.S. WE regret to announce the death of Dr. Augustus Henry Collet, which occurred at Worthing. Dr. Collet, who was within a few days of his 65th birthday, was a native of Worthing, and a member of a highly respected local family. He was prominently identified with local movements, and held some imidentified with local movements, and field some important public positions. He was appointed a member of the honorary medical staff of the Worthing Hospital on December 29th, 1871, following Dr. A. Sharpe, who, in 1864, had succeeded Dr. H. J. Collet. In 1887 the retirement of Mr. W. J. Harris from the medical staff, after nearly 24 years' service, placed Dr. A. H. Collet in the position of Senior Medical Officer, which he held until the last. During the past year he was elected Chairman of the Committee of Manager. was elected Chairman of the Committee of Management. Dr. Collet had by far the longest record of service for the Hospital, having been connected with the institution for 37 years.

#### SAMUEL CLEWIN GRIFFITH, M.D.ST.AND., M.R.C.S.ENG.

WE regret to announce the death, in his 80th year, of Dr. Clewin Griffith, at his house in Woburn Square, London, on March 15th, after a long illness. His father many years ago was a well-known practitioner in Gower Street, and reached the advanced age of 90 years.

The son was for some time in practice in Finsbury Square, and a few years ago filled the office of Master of the Society of Apothecaries. A portrait of his father, who was also a Master of the Society, may be seen at Apothecaries Hall. Dr. Clewin Griffith and his wife, who died several years ago, were forward in a variety of useful and philanthropic works, and their loss will be much felt.

Deceased was educated medically at St. Bartholomew's, University College and Paris. He was M.D. of St Andrew's, M.R.C.S.Eng. (1846), and I.S.A. (1847).

#### MATTHEW DICKSON, M.D.ABER.

WE regret to announce the death of Dr. Matthew Dickson, of Liverpool. Born in Rhynie, Banffshire, in 1842, he was educated at the Aberdeen Grammar School, Marischal College, and Aberdeen University. In his early medical life he was Surgeon to an Arctic expedition, and later two years at the Liverpool Medical Mission. He was also for seven years Medical Missionary in Formosa in connection with the Presbyterian Church of England. Being an ardent naturalist, in many of his journeys he carefully studied the flora, fauna, and ethnology, particularly of Formosa, sending home considerable collections. He discovered several new species of shells, one of which is named after him—Melania Dicksoni.

## EDGAR OSWALD HOPWOOD, B.A., M.D.Oxon., D.P.H.

WE regret to record the death, at his residence at Manchester, of Dr. Edgar Oswald Hopwood, who was well-known in connection with the work of the London Fever Hospital. Of modest and reserved temperament, Dr. Hopwood made himself little known in the medical world, but those associated with him realised that he was one of the soundest authorities on fever in the country. His judgment in diagnosis was particularly good, but he was content to pass his life in the quiet of hospital residence, without seeking to achieve fame outside.

#### REVIEWS OF BOOKS.

PRIESTS OF PROGRESS. (a)

This book is described in the advertisement which accompanies it as "a work of enthralling interest, which sets forth the case against vivisection with a power, vividness and realism which is likely to win many converts to the anti-vivisection cause." It is, we suppose, on account of the views which the author puts forward, and not on account of the story, that we have been asked to review the book, and we shall in consequence deal with it from that point of view The author in his preface states that the methods described are real methods recounted scientific journals, but here attributed to characters essentially and entirely fictitious." Furthermore, we have in an appendix a list of the authorities "for the actual theories and practices attributed to those characters." In this way the author has given a semblance of reality to his story, and will, we have no doubt, create a feeling of belief in the minds of some of his readers in the truth of his inferences and in the sincerity of his arguments. As an example of this we may cite an incident, perhaps the most striking in the book, in which an operation is described as having taken place in a London hospital, and of which the author was informed by a doctor whose friend, a surgeon, witnessed it." The patient, S. J., a young woman, was admitted for treatment of what the doctor described "as ulceration of the skin, just a surface thing." The operation performed, however, by a leading London surgeon, and apparently without the consent of the patient, was excision of the superior maxilla. Furthermore, we are led to believe that the reason for doing this operation was not the diseased condition of the patient, but merely that the surgeon might demonstrate to the class his skill in the performance of a difficult and dangerous operation. That such an incident as this ever took place in any hospital we beg leave to doubt, and further we are convinced that any-one who believed that it did, and had evidence in support of that belief, would be guilty of a grave moral offence in suppressing any of that evidence. If our author has evidence in support of the truth and reality of this incident, as he would lead us to believe he has, his suppression of that evidence is so damaging to his moral character that his views on other questions of morals can have little weight. On the other hand, if he is not in possession of this evidence the way he has introduced the incident into his book is, to say the least of it, disingenuous.

We are, however, inclined to join issue with the supporters of the anti-vivisection movement on the fundamental principle which underlies their position. This principle, stated broadly, is that the infliction of pain when not for the good of the person or animal on which it is inflicted, is wrong, and may be considered as cruelty. If this position be once granted, all experiments on the lower animals are, of course, unjustifiable. The word "cruelty" has at least two meanings which should be carefully distinguished—

(a) "Priests of Progress." By G. Colmore. 8vo. Pp. 392. London: Stanley Paul and Co. 1908.

(1) a disposition to inflict suffering, delight in or indifference to the pain or misery of others; and (2) severity of pain or excessive suffering. Experiments on animals may involve cruelty in the latter sense without the necessary attribution of moral culpability to the experimenter. But this distinction is not kept in view by the anti-vivisectionist. An experiment involves pain, perhaps severe pain; it is at once spoken of as cruel, and the experimenter stigmatised. But what grounds are there for maintaining that the infliction of pain is morally wrong? Throughout the entire animal kingdom, from the lowest organism to the highest, we see that organism lives, and can only live, by preying on others, and thus inflicting pain. Man obtains a large part of his food by killing other animals, and the ultimate sanction of the law which protects the community is the right to inflict pain on those who transgress the law. The penalty of the law is for the protection of the community, and not for the good of the individual punished. It seems idle, then, to argue that the infliction of pain is in itself evil. But the infliction of pain may readily become an evil if the motive of the action is an evil one, and in this sense our author is right when he says that vivisectors maintain that the end justifies the means, but he is wrong if he thinks that in this sense the statement is the opprobrium of ethics. The means are here moral or immoral, according to whether the motive is good or bad.

It will be urged that this argument would as well justify experiments on human beings as on the lower animals, and so it would were human beings merely animals. But since human beings are believed to be something more than animals, the community has deprived the individual of the liberty of treating a human being as he would treat an animal. When experiments are tried on a human being, it is either because the individual has given consent, or because it is believed that the experiment will result in benefit to that individual.

It seems unnecessary to follow our author through all his various arguments, believing, as we do, that the fundamental basis of them is false. There is one, however, which we should like to mention—namely, the objection to the use of therapeutic agents derived from animals, which practice our author considers—and rightly—as one of the results of vivisection. This practice is described as the injection into people of "animal nastiness." We fail to see, if an animal's flesh may be used for food, why its serum should not be used to cure disease, and, if to cure, why not to prevent.

We have devoted our entire consideration to the views expressed in the book, because with them, and not with the story, we, as a medical journal, are concerned, but we may say that, apart from the sceptical views, the story is of little interest, and will not probably attract many readers.

#### THE KNEE-JOINT. (a)

THIS book deserves the attention that its distinguished authorship cannot fail to attract. It is an excellent little monograph, written in the language of an experienced teacher for the benefit of "those who have as yet had less experience than the writer."

While it is by no means an exhaustive treatise on the knee-joint and its ailments, we can commend it to students and practitioners possessing ordinary acumen, as it is likely to prove very helpful to them in familiarising themselves with the crucial points concerned in the differential diagnosis of diseases and injuries connected with this joint. Sir William Bennett's wide clinical and anatomical experience has led him to the belief that unilateral hypermobility is suggestive either of disease or some physical defect, and that the integrity of the joint is largely dependent upon the ilio-tibial band. In treating acute effusions into the knee-joint, the author is opposed to immobilisation and cold applications. He relies on the hyperæmic treatment and hot compresses. As soon as

(a) "Injuries and Diseases of the Knee-Joint. Considered from the Cliuical Aspect." By Sir William Bennett, K.C.V.O., F.R.C.S. With thirty-four illustrations. London: James Nisbet and Co. 1909.

the tension shows signs of diminishing, he adopts gentle movement and massage. The chapters on painless effusion, pain in and about the knee, and recurring effusion after injury, will repay perusal. Chapters VIII. and IX. are devoted to that all-important subject, "Internal Derangements of the Knee." The author supports his opinions by the records of numerous cases that have come under his records of numerous cases that have come under his observation both in private practice and at St. George's Hospital. He deprecates operations in the presence of fluid in the joint, and recommends passive or voluntary movement at the end of a week. In ordinary cases, he says, patients should be walking in a fortnight. He contrasts this modus operandi with that recommended in the latest American work on surgery edited by Keen, viz. —"Fixation for two or three weeks should follow, after which massage and passive manipulations are begun." Early tuberculous disease and induced hyperæmia in the treatment of affections of the knee-joint are well sketched in the two concluding chapters. The X-ray photographs are good.

MANUAL OF BACTERIOLOGY. (a) THE preparation of the third edition of this deservedly famous book has been undertaken with conscientiousness. The text has been brought well up to date; practically all the recent research of any importance being prepared for the reader's assimilation. Many new illustrations add to the helpfulness of the book, diagrams illustrating Ehrlich's side-chain theory being included. Among the additions, the portions dealing with vaccines, opsonic indices, and recently discovered protozoa may especially be commended to the reader's attention.

The chapter on the "Examination of Water" is

thoroughly up-to-date, and has been rewritten in a manner calculated to be of the greatest service to the student. Incidentally, we notice that the author, bearing in mind a lament at the beginning of the book about the chaotic condition of bacteriological nomenclature, is precise as to his terminology; hence we have "ptomine," "B. Welchi," etc. Errors are almost absent, the only ones we have noted being—"mercuric chloride" being substituted for "carbolic acid" on page 605, and the coefficient of mercuric chloride being given as 400. The latter figure refers to tests in which no attempt was made to preclude antiseptic action in the sub-cultures—when this was done Walker showed that the carbolic acid coefficient dropped to 20. Also, when discussing the results of anti-typhoid inoculation, "inoculated" is obviously meant for "uninoculated" (page 343, line 20).

THE PRACTICAL MEDICAL SERIES. (b)
This is the second medical volume of this series for the year 1908, the first of which was reviewed in our columns some months ago, and we are glad to say that the present volume maintains the high opinion that we then expressed of the series. The recent work on the various diseases with which the volume deals is admirably epitomised, and references given to the original papers. Very considerable space is given to typhoid fever and to diseases of the stomach, indeed, more than half of the book is taken up with these important subjects, the work on which is gone into most fully. We cannot say that we have detected any omissions of importance, and the admirable index, both of subjects and authors, makes the task of searching for any paper an easy one. The present volume is marked No. VI., being the sixth of the series for 1908, the former medical volume of the year being No. I. We would suggest to the publishers that as many medical men will not require the entire series, that the volumes dealing with same subjects should be marked consecutively. A practitioner nowadays can hardly afford to be without some such book, and of its kind it, the present volume, is one of the best we have seen.

DICTIONARY OF MEDICAL TREATMENT. (a) THE object of this little book is to present to the practitioner a definite course of treatment for any disease which is commonly seen in medical practice. We are not sure that such a work is suited to the requirements of students, who are more in need of studying principles than methods of treatment. To the junior practitioner, however, such a work presents many advantages, since it helps him in the applica-tion of those principles at a time when as yet his methods have not been, as it were, crystallised by experience. The methods which are here taught are excellent, a due proportion being maintained between those of a general nature and the prescription of drugs. There is also an admirable description of the newer methods, including vaccine therapy. Of this the author has evidently had a good deal of experience, and we are glad to hear him speak so highly as he does of the method. We can heartily recommend the perusal of this book to junior practitioners, and believe that many who are no longer junior will find much to interest them in it.

FOOD MICROSCOPY. (b)

Few medical men realise the deep debt of gratitude the world owes to the late Dr. A. H. Hassall for his researches on the microscopical structures of food materials. His labours placed the detection of adulteration on a sound scientific basis, and very considerably restricted the activities of the food sophisticator. Since the appearance of Hassall's work, "Food: Its Adulteration and the Methods for their Detection," thirty-two years ago, a certain amount of been done, and a revision and additions were necessary to make the work up-to-date. For this task it would have been difficult to find a more suitable editor than Mr. Clayton, who has himself enriched our knowledge of the subject in most valuable ways, and who, as the personal friend of Hassall, can be depended on to render this work a worthy successor to the original one. It is obvious that this revision has been no light work, but it has been accomplished in a manner that Hassall himself, were he still with us, would be the first to appreciate, and to say this is perhaps the greatest compliment we can tender to the author. A very large amount of new matter has been incorporated, and the volume will be found indispensable to the Medical Officer of Health, to the candidate for State Medicine examinations, and to the Public Analyst. A careful perusal of the book has failed to reveal any errors, and, with the exception of a few instances where a difference of opinion may be expected, we find nothing to criticise. The sections on water and parasites may be singled out for especial commendation. The illustrations are invariably accurate, and will allow that sense of safety to the laboratory worker that he is often unable to feel after a scrutiny of the indistinct micro-photographs and diagrams that often have to serve him at the present

THE St. John Ambulance Association has received from Lord Rothschild, Chairman of the British Red Cross Society, two Diplomas of Honour, forwarded by Prince Hilkoff, Secretary of State to his Majesty the Emperor of Russia and President of the Russian Red Cross, awarded to the Association by the Committee of the Empress Marie Féodorovna Funds for the diminution of the sufferings of the sick and wounded in war.

# MEDICAL NEWS IN BRIEF.

#### Royal Visit to the London Hospital.

On Monday last, H.M. the Queen and the Empress Marie Feodorovna paid a visit to the London Hospital, Whitechapel. The Royal visitors were received by the Hon. Sydney Holland, chairman of the hospital; Mr. Buxton, vice-president; Miss Lückes, matron; Mr. E. W. Morris, secretary; and representatives of the medical and surgical and nursing staffs.

In the four wards which they visited the Queen and Empress had a kindly word for each of the patients. In the Finsen light department, which owes its origin mainly to her initiative, the Queen remained a considerable time, and talked with several of the patients who are undergoing treatment. From there the Royal wno are undergoing treatment. From there the Royal party proceeded to inspect the new radiant heat baths, installed for the cure of rheumatism, after the style of those in use at Carlsbad. The donor of these baths was Princess Hatzfeldt, whose generosity was directed into this particular channel by a suggestion from King Edward.

In the surgical ward visited were 56 beds, and the visitors did not miss a single patient. They spoke to all in turn, and asked many questions of the matron and sisters in attendance. The Royal party remained at the hospital for an hour and a-half.

#### West London Hospital.

AT the annual meeting of the West London Hospital, Hammersmith, the Duke of Abercorn, President of the hospital, who occupied the chair, appealed for annual subscriptions, and also said there had been a large diminution in legacies and donations. desired to improve the accommodation provided for the nurses. He moved the adoption of the report. The Bishop of London, in seconding, said it was one of the best traditions of our English life that men in positions such as that occupied by their chairman should take a keen and active interest in philanthropic institutions. He himself had earned a certain amount of popularity by sending an injured man in his carriage to that hospital, which was doing an excellent work. It was a kind of lifeboat for that part of London, and he was sorry that it was heavily in debt. The large sum given by the King's Hospital Fund was a distinct vote of confidence, and he hoped the local religious bodies would stand by the hospital.

#### Administration of Anæsthetics.

By the Medical Acts Amendment Bill, which has been drafted by Dr. Cooper, M.P., a medical practitioner applying for registration on or after January 1st, 1911, will be required to submit evidence of having received practical instruction in the administration of anæsthetics, and any person not a registered medical practitioner will be prohibited from administering an anæsthetic, except under certain conditions, to safeguard the rights of all persons registered as dentists before the commencement of the Act. It is also intended to prohibit any certificate of death being given in the case of any person dying under an anæsthetic.

#### Tuberculous Milk.

Out of 456 samples of milk sent to London between January 18th and March 25th last, the examination by the County Council of 299 has been completed, with the result that 37 samples (or 12.4 per cent.) have been proved to be tuberculous. The Council's veterinary inspector visited 125 farms outside the county, and inspected 2,641 cows, of which 92 (or 3.5 per cent.) were found to be suffering from tuberculosis of the udder. In every case in which a tuberculous udder has been diagnosed, the dairy farmer, or his representative, has undertaken to sell no more milk from the affected

#### Seciety for the Study of Inebriety.

THE annual meeting of the Society will be held in the rooms of the Medical Society of London (11 Chandos Street, Cavendish Square), on Tuesday, April

13th, at 4 p.m. (Afternoon meeting). Business:—To appoint Officers and Council for the ensuing Session, and to receive the report of the Council and the financial statement. A short address will be delivered by the President, after which a discussion on "Alcoholism and Eugenics" will be opened by C. W. Saleeby, M.D., F.R.S.E. Each member and associate is at liberty to introduce a visitor. Tea and coffee at 3.45. Council meeting at 3.30.

The minimum annual subscription to the Society being a merely nominal one (5s., including a copy of the British Journal of Inebriety, post free), the Council has resolved that a reserve fund be established to further the work of the Society, and every member and associate, and all interested in the scientific study of alcoholism, are earnestly invited to forward contribu-tions to the Hon. Treasurer, G. Basil Price, M.D., 53. Devonshire Street, Portland Place, W.

Gresham College.

FOUR Lectures will be delivered by Dr. F. M. Sandwith, Gresham Professor, on Tuesday, Wednesday, Thursday, and Friday, April 20th to 23rd, 1909, at six o'clock each evening, the subject being, "Cancer, its History, Geographical Distribution, Theories of Causation, Symptoms and Treatment."

## The Porthcoming Bazaar for Mercer's Hospital and the Orthopædic Hospital, Dublin,

A very influential meeting was held in the Royal College of Surgeons in Dublin on March 30th, under the Presidency of Lady Aberdeen, for the purpose of explaining the results of the work of the promoters of the large bazaar which is to be held at the Royal Dublin Societies premises from May 25th to 29th next, to obtain funds for the hospitals named above. satisfactory reports of the work done were presented to the meeting, and it is evident that the bazaar will be a great success. It is now some time since a bazaar on a large scale has been held in Dublin, and we hope and believe that the promoters' efforts will result in the addition of a large sum to the funds of the

#### Increase of Cancer in Germany.

News reaches us from Germany that Professor Johannes Orth, an authority on cancer, has just published a report on the experiences which he has gathered during a quarter of a century of practical study of this disease. He states that there has been a steady increase of fatal cases of cancer from year to year during the last 30 years, which has advanced beyond the proportionate growth of population from year to year.

Men are, on the whole, he finds, more liable to Certain kinds of cancer are cancer than women. more prevalent among women, but other kinds, such as cancer of the throat, the lip, or tongue, are far more prevalent among men. Cancer of the stomach also appears more prevalent among men. Pro-fessor Orth does not agree with the conclusion arrived at by other eminent physicians that cancer is becoming more prevalent at the earlier ages of patients than was formerly the case.

#### Slavery and Cocoa.

MESSES VAN HOUTEN AND Co., the well-known cocoa manufacturers, ask us to state that in view of the wide publicity which has been given to the fact that certain cocoa manufacturers have at last decided to discontinue the practice of purchasing cocoa beans produced by slave labour in the Portuguese West African territories of St. Thomé and Principe, that during the 80 years they (Messrs. Van Houten) have been producing cocoa, they have never purchased beans grown in slave-affected areas. In selecting the raw material they have always strictly adhered to the policy of purchasing cocoa beans of the highest quality only, produced under the most satisfactory conditions, and they have, therefore, never entertained the idea of procuring beans from West Africa.

#### Unusual Surgical Case.

An inquest was held at Chelsea, on April 3rd, by Mr. C. L. Drew on the body of Alfred James Wilson,

aged 4½ years, the son of a labourer, of Markham Street, Chelsea. The child had been taken to Victoria Hospital to undergo an operation for some brain trouble. During the operation it was found that a small vein had adhered to the scalp and was torn,

causing death.

Dr. Waterhouse said he considered the case unique in British surgery, and it was likely to be of value to

surgeons.

Dr. Spillsbury, pathologist at St. Mary's Hospital, also said that he had never known such a case before. The jury's verdict was "Death by misadventure."

### Reyal College of Surgeons in Ireland,—Prize List, Winter Session, 1908—1909.

Descriptive Anatomy.—Junior.—W. I. Adams, First Prize (£2) and Medal; G. E. Pepper, Second Prize (£1) and Certificate. Senior.—M. J. Hillery, First Prize (£2) and Medal; I. M. Swanepoel, Second Prize (£1) and Certificate.

Practical Anatomy.—First Year.—G. E. Pepper, First Prize (£2) and Medal; H. A. S. Deane, Second Prize (£1) and Certificate. Second Year.—A. G. Mosbery, First Prize (£2), and Medal; I. M. Swanepoel, Second Prize (£1) and Certificate.

Practice of Medicine.—W. V. Johnston, First Prize (£2) and Medal; J. S. Pegum, Second Prize (£1) and

(£2) and Medal; J. S. Pegum, Second Prize (£1) and Certificate.

Surgery.—J. S. Pegum, First Prize (£2) and Medal. Midwifery.—F. W. Warren, First Prize (£2) and Medal; J. S. Pegum, Second Prize (£1) and Certi-

Physiology.—S. Griffin, First Prize (£2) and Medal; M. J. Hillery, Second Prize (£1) and Certificate. Chemistry.—J. C. Sproule, First Prize (£2) and Medal; B. Goldberg, Second Prize (£1) and Certificate.

Pathology.—J. T. Duncan, First Prize (£2) and Medal; T. M. Thomson, Second Prize (£1) and

Physics.—E. Connell, First Prize (£2) and Medal; C. Sproule, Second Prize (£1) and Certificate. The Lectures and Practical Courses of the Summer

Session commenced on Thursday, April 1st.

#### 1 be Measles Epidemic in Birmingham.

THERE are indications of the decline of the epidemic of measles which during the past two months has proved so serious a menace to the children of Birmingham. For several weeks past the death roll has exceeded 40, for the week ended March 22nd it was 46, whereas last week it was only 31, a gratifying decrease of 15 deaths. The improved weather is probably an important factor in the matter, and as the meteorological conditions improve and the temperature advances the number of deaths, it is expected, will continue to diminish.

Last week, too, there was a decrease in the number of deaths attributed to influenza and phthisis. Unfortunately there was an increase in the number of fatal cases of diphtheria and whooping-cough, and therefore, whilst the general death-rate for last week was 21.4 per 1,000 of the population, as compared with 25.1 for the preceding seven days, the zymotic deathrate for the parallel periods was practically the same, being 4.4 per 1,000 for last week, and 4.8 for the previous week.

#### PASS LISTS.

#### **Liniversity of Durham**

First Examination for the Degree of Bachelor of

First Examination for the Degree of Bachelor of Medicine, March, 1909.—The following candidates have satisfied the Examiners:—Elementary Anatomy and Biology, Chemistry and Physics (Honours—Second Class): William S. Murray, Edward Phillips. Elementary Anatomy and Biology.—Robert E. Bell, G. A. Berkeley-Cole, Garfield Carse, Herbert G. Dodd, Cyril Duncan, Idris D. Evans, Reginald A. Hooper, Robert L. Kitching, Nora Murphy, Carinna A. B. O'Neill, Arthur Patterson, Lionel G. Pearson, James M. Phillips-Jones, Evelyn Ritson, Donald C. Scott, Cedric O. Shackleton. Arthur Sutcliffe. Cedric O. Shackleton, Arthur Sutcliffe.

Chemistry and Physics.—Edgar Babst, Philip Gunn, Frederick W. C. Hinings, Sydney E. Murray, Cecil T. G. Pearce, Sidney Scott, Andrew Smith, Herbert J. Shanley.

John S. Arkle passed in Chemistry, Elementary Anatomy and Biology, and Walter A. Elliott in Elementary Anatomy.

Second Examination for the Degree of Bachelor of Medicine (Honours—Second Class).—Sam P. Bedson. B.Sc., passed in Anatomy, Physiology, and Materia Medica.

Pass List.—F. E. Chapman, William L. Clements, Harold Fairclough, Louis E. S. Gellé, James K. J. Haworth, William J. Hickey, Edwin Kidd, William G. Lidderdale, Colin Mearns, Benjamin B. Noble, James A. C. Scott, William A. Slater, Robert W. Smith, Russell V. Steele, Henri R. G. Vander Beken.

Third Examination for the Degree of Bachelor of Medicine.—The following passed in Pathology, Medical Jurisprudence, Public Health, and Elementary Bacteriology.—William G. Bendle (Honours, Second Class), Bloomfield G. H. Connolly, Roger Errington, Francis P. Evers, Eric L. Hancock, Howard T. Hunter, Eva Lumb, Ernest P. Martin, Alfred T. Thompson, Thomas R. West.

#### University of Glasgow.

THE following candidates have passed the Fourth (Final) Professional Examination for the Degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.): -John Allan, James G. Anderson, William (Ch.B.):—John Allan, James G. Anderson, William H. S. Armstrong, Douglas M. Borland, Morris W. Browdy, John A. G. Burton, John Cameron, Matthew I. T. Cassidy, Weir B. Cunningham, James C. Dick, Alexander G. Gilchrist, George S. Gordon, Edward O'D. Graham, James Harper, M.A.; William Howat, M.A.; John P. Kinloch, David N. Knox, Alexander M. Macdonald, Murdo D. Mackenzie, George Macleod, M.A.; Allan M'Pherson, Thomas-Marlin, Henry N. Rankin, Alfred Roemmele, William W. Rorke, William Rutherford, James J. Sinclair, Arthur Turnbull, M.A., B.Sc.; James B. Whitfield, John A. Wilson.

The following passed with distinction in the sub-

The following passed with distinction in the subjects indicated:—In Surgery and Clinical Surgery, Practice of Medicine and Clinical Medicine, Midwifery—George Macleod, M.A. In Surgery and Clinical Surgery, Midwifery—William Howat, M.A.; William Rutherford, Alexander Stewart. In Surgery and Clinical Surgery—Winifred M. Ross, James J. Sinclair, Arthur Turnbull, M.A., B.Sc. In Midwifery—Matthew I. T. Cassidy, John P. Kinloch, Robert C. Robertson, William W. Rorke.

#### Trinity College, Dublin.

THE following candidates passed the Intermediate-THE following candidates passed the Intermediate-Medical Examination at Hilary Term, 1909:—Part II.—Harry L. W. Woodroffe (passed on High Marks), Robert W. Murphy; Arthur F. B. Shaw and H. Jocelyn Smyly (æq.); Francis C. Crossle, James M. Elliott; Hugh M. Fleming, Thomas G. Harpur, Albert E. Malone (q.); Charles O'Brien, Mary G. Caskey, George J. Meldon, Edgar N. Bateman, Gerald P. Beckett, Frank Crosbie, Matthew M'Knight; James Beckett, Ronald G. M'Entire (æq.).

Ernest S. Friel passed the Previous Dental Examination.

MR. JOHN KERSHAW, F.R.C.S., of North Drive, St. Annes-on-the-Sea, Lancs., who died on February 14th, left estate of the gross value of £79,195 3s. 7d., of which the net personalty has been sworn at £67,129 9s. 1d. The testator bequeathed £10,000 to be distributed by the executors in accordance with memoranda left by him; and to the Victoria University of Manchester his Egyptian Canopus (Cynoce-The residue of his property he left upon phalus). trust for the founding, establishment, maintenance, or endowment of a general hospital and infirmary in the township of Royton, Lancashire.

#### **NOTICES TO** CORRESPONDENTS. &c.

Conrespondence requiring a reply in this column are particularly requested to make use of a Distinctive Signature or Initial, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessary for publication but as evidence of identity.

ADVERTICEMENTS.

ADVERTICEMENTS.

ADVENTICEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.;
Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

&c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

KATHERINE X.—You will want a microscope on your expedition. It should, however, be capable of standing hard wear, and at the same time be strong and portable. If you care to write us more fully, we will make inquiries in the proper quarter. Horfield (Bristol).—Those who talk so earnestly about the necessity of reducing the infantile mortality would do well to try and lessen the evil by checking the sale of patent medicines, which are, beyond a doubt, responsible for many deaths of infants and young children.

ARMI SURGEON.—We are well aware of the elaborate methods of gastrio investigation which you describe. In the opinion of many leading physicians they should be relegated to the laboratory, as they do not, as a rule, advance either diagnosis or help treatment.

MISTURA FERRI GALLICI.

To the Editor of TRE Medical Press and Orrecular.

SIR.—Your comments in last issue on above subject are amusing, and, I presume. ""concal." The idea of feeding hens on rust derived from nalls, scraps of iron, etc., emanates, of course, from a "lay" journal, a "foul" suggestion at best. In course of time, by evolution, the bens might be induced to layer priately stored in the hatchway of warships, and when supply became short the ship might be obliged to "lay to" anyway!

I am, Sir, yours truly,

A. D.

A. D.

London, W.

SURGEON-GENERAL O'D.—It is a fact that Poor-law children cannot be sent by Guardians to the training-ship Exmouth, except with consent of the parents. No doubt that difficulty accounts for the small use that is made of that most excellent organisation by local authorities. A service would be done to the ratepayer, as well as to the naval authorities, were the many advantages offered by the training-ship Exmouth to be widely impressed upon the public.

T. A. CROTHERS.—Although the spread of measles has never been actually traced to the agency of flies, it would be unsafe to exclude that possibility from any detailed scheme of prevention.

EUTHANASIA

to exclude that possibility from any detailed scheme of prevention.

EUTHANASIA.

EUTHANASIA is a word of various meanings. The sense in which you use it, namely, that of putting to death human heings who are hopelessly sick, or otherwise useless to society, is no new idea in the speculations of moral philosophy. Some persons hold that it would be better to begin at the other end of the stick, and prevent the marriage of the unfit, and at the same time destroy defective infants. It will probably take a good many centuries for mankind to arrive at a satisfactory solution of the problem. Pessibly eugenics may out the Gordian knot by evolving a perfect race.

Labrador.—The fruit of the pincapple, it is stated, contains a digestive principle closely resembling pepsin in its action. On the casein of milk pincapple juice acts as a digestive in almost the same degree as rennet. Hence the juice is indicated in some forms of dyspepsia.

Dr. W. H. B.—Statistics have recently shown that the birthrate is falling in the United States, and not increasing, as our correspondent suggests. In a lecture delivered at the Cornell tuiversity on Births and Birth-rate, towards the end of last year, the statement was made that from 1860-1900 the proportion to each 1,000 women of child-bearing age in the United States has decreased by 152, or an average of about 30 in each decade. This means that the continuance of this decrease, if unchecked, would, in a century-and-a-half, eliminate the birth-rate entirely.

## Meetings of the Societies, Tectures, &c.

WEDNESDAY, APRIL 77H.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tettenham, N.).—Clinics: 2.30 p.m: Medical Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks).

THURSDAY, APRIL 87H.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.50 p.m.: Gynrocological Operations (Dr. A. E. Giles). Clinics: Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. H. W. Carson); X.Rays. 5 p.m.: Medical In-patient (Dr. G. P. Chappel). Demonstration: Dr. F. Thomson: Infectious Fevers (at the North-Eastern Fever Hospital, St Ann's Road, N.

FRIDAY, APRIL 97H.

NORTH-EAST LONDON POST GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—10 a.m.: Clinic: Surgical Out-patient (Mr. H. Evans). 2.50 p.m.: Operations: (Mr. W. Edmunds). Clinics: Medical Out-patient (Dr. A. G. Auld); Eye (Mr. R. P. Brooks). 3 p.m.: Medical In-patient (Dr. R. M. Leslie).

MANSON, J. S., M.B., Ch.B.Edin., Honorary Assistant Surgeon to the Warrington Infirmary.

MILINE, LINDSAY S., M.B., Ch.B.Edin., First Assistant in the Russell Sage Institute for Pathology, New York, U.S.A.

MORDE, EDWARD, L.R.C.P. and S.Edin., Medical Officer of Health of Torrington (Devon, M.B., C.P.Lond., M.R.C.S., Medical Superintendent of Wonford House, Exeter.

ROSE, WILLIAM, M.B., B.S.Lond., F.R.C.S.Eng., Consulting Surgeon to the British Hospital for Mental Disorders and Brain Diseases, Camden Road, N.W.

SIMPSON, HAROLD C., L.M.S.S.A.Lond., Medical Officer of Health for the Skirlaugh Rural District Council, Hull.

WHITE, CLIFFORD, M.D., B.S.Lond., M.R.C.P.Lond., Pathologist and Registrar to Queen Charlotte's Lying-in Hospital.

#### Vacancies.

Birkenhead Union.—Resident Assistant Medical Officer. Salary. £120 per annum, with board, washing, and apartments. Applications to John Carter, Clerk to the Guardians, Poor-Law Offices, Conway Street, Birkenhead.

Metropolitan Borough of St. Marylebone.—Medical Officer of Health. Salary, £500 per annum. Applications to James Wilson, Town Clerk, Town Hall, St. Marylebone, W. County Asylum, Rainhill, near Liverpool.—Assistant Medical Officer. Salary, £150 per annum, together with furnished apartments, hoard, attendance, and washing. Applications to the Medical Superintendent.

Township of Manchester.—Assistant Medical Officer. Salary, £130 a year, with furnished apartments, fire, light, washing, and attendance. Applications to James Macdonald, Clerk to the Guardians, Poor-Law Offices, New Bridge Street, Manchester. Urban District Council of Barking Town.—Medical Officer of Health. Salary, £350 per annum. Applications to H. Hargraeves, Clerk, Public Offices, Barking, Essex.

Staffordshire County Asylum, Cheddleton, Leek.—Temporary Assistant Medical Officer. Salary £150 per annum, with apartments, board and washing. Applications to the Medical Superintendent.

The Hospital for Sick Children, Great Ormond Street, London. W.C.—House Surgeon Salary £30 for six months, washing allowance £2 10s., with board and residence in the Hospital. Applications to the Secretary. (See advt.)

The Hospital for Sick Children, Great Ormond Street, London. W.C.—Assistant Casualty Medical Officer. Salary £30 for six months, washing allowance £2 10s., and board and residence in the Hospital. Applications to the Secretary. (See advt.)

#### Births.

ARMSTRONG.—On March 30th, at Jaffna, London Road, Reading, the wife of Dr. E. Frankland Armstrong, of a son.

SCOTT.—On March 31st, at 46, Queen Anne Street, Cavendish Square, London, the wife of Sydney R. Scott, M.S.Lond., F.R.C.S.Eng., of a son.

SMITH.—On March 30th, at Digby House, Melton Mowbray, the wife of James A. Smyth, M.B., of a son.

#### Marriages.

DICKEY—CARTER.—On March 27th, at Christ Church, Turnham Green, William Crautuird McNaghten Dickey, M.R.C.S.Eng., L.R.C.P.Lond, only son of W. Crautuird Dickey, dental surgeon, of Chiswick, to Rosamond Alice, only daughter of Mr. and Mrs. Charles Carter, of Brighton.

#### Beaths.

GEOGHEGAN. - On April 2nd, after a long illness, Alfred Osmond Geoghegan, M.D., Lieut. - Colonel R.A.M.C. (Retired), in his 53rd

Geoghegan, M.D., Llett., Colonier R.A.M.C., (Newfield), in his con-year.

GRAY.—On April 2nd, at The Grange, Westbourne Road, Birkdale,
Alice Penrose Gray, aged 43, widow of the late Andrew Gray,
M.D., 8t. Helens, and daughter of E. P. Twyford, M.D., late of
St. Helens.

Ramsbortham.—On March 30th, at Fairstead, Harrogate, Samuel
Henry Ramsbotham, M.D.Edim., M.R.C.S.Eng., late of Leeds,
oldest son of the late John Hodgson Ramsbotham, M.D.,
F.R.C.S., aged 70 years.

Wilson.—On March 31st, at the London Hospital, of blood poisoning, after a short illness, Angus Bewley Wilson, M.B.Cantab.
house physician, second son of A. Christy Wilson, M.D., Hall
trate, Doncaster, aged 32 years.

ووووواواواواوافافافافاقا

An Ideal Tonic in Convalescence.

An Active Aid to the Digestion of Farinaceous Foods.

'Byno' Hypophosphites may be taken when the digestive organs are weak and impaired, and when ordinary tonics cannot be tolerated.

THE constituents of 'Byno' Hypophosphites ensures the effectual combination required in a perfect tonic. This combination, though somewhat complex, is in practice most successful, and 'Byno' Hypophosphites will be found much superior to the official syrup of which it is the analogue. It stimulates the appetite whilst aiding digestion; it conserves and invigorates the nervous system.

PRACTICAL CLINICAL EXPERIENCE of many years has proved that what theoretically is expected of 'Byno' Hypophosphites by reason of its composition is fully justified. It is, as the British Medical Journal says,

"One of the Most Popular Tonics of the Day."

SAMPLES SENT FREE TO MEDICAL MEN, ON REQUEST.

# ALLEN & HANBURYS Ltd.,

37, Lombard Street, LONDON, E.C.

UNITED STATES: Niagara Falls, New York. CANADA: Gerrard Street East, Toronto.

AUSTRALASIA: Bridge and Loftus Streets, Sydney. SOUTH AFRICA: Castle Street, Cape Town.

# HOMMEL'S Hæmatogen

CONTAINS NEITHER ALCOHOL NOR ANTISEPTICS

A combination of 80 parts purified and concentrated Hæmoglobin with 20 parts chemically pure Glycerine and Aromatic Flavouring.

The best of all the existing preparations of Hæmoglobin. More efficacious than Cod-Liver Oil or the ordinary manufactured preparations of Iron. Very strengthening both for Children and Adults. An energetic Blood Former. Increases the Appetite. Aids Digestion.

Extremely useful in Rickets, Scrofula, General Debility, Ansemia, Weak Heart, Neurasthenia, and Convalescence from illness such as Pneumonia or Influenza.

Unsurpassed as a Strengthening Restorative in Diseases of the Lungs. Has a very agreeable taste, and is taken with the utmost relish even by Children.

FREE FROM BACTERIAL GROWTH. UNCHANGED BY KEEPING.

These important qualities are guaranteed by using the highest permissible temperature in the process of manufacture (130° to 140° Fahr. for 24 hours). No guarantee of this description is possible for preparations made by a cold process with ether.

In prescribing, always state "HOMMEL'S" Hæmatogen as spurious imitations are offered.

ONLY SUPPLIED IN FLUID, NOT IN CAPSULES OR OTHER FORMS.

The from Half to One Teaspoonful twice a day in milk.

Children

Mults - Take from Half to One Teaspoonful twice a day in milk.

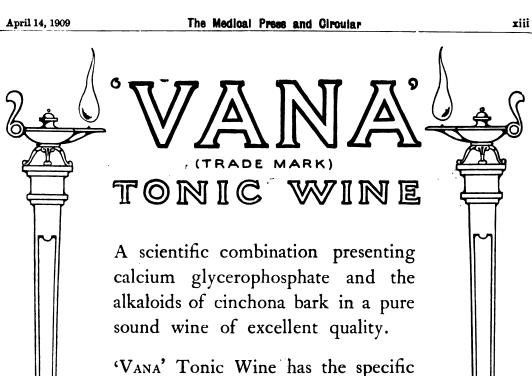

" One or Two Dessertspoonfuls daily, either pure or mixed with any convenient liquid.
" One Tablespoonful avice a day before the two principal meals.

SAMPLES AND LITERATURE, gratis and carriage paid, on application.

MICOLAY & CO., 36 & 36a, ST. ANDREW'S HILL, LONDON, E.C.

The Non-Toxic

# Cyllin Bactericide

Has a guaranteed Rideal-Walker Co-efficient of 20.0. It is therefore equal to Perchloride of Mercury as a bactericide. (Vide "The Medical Press," Feb. 14, 1906.)

N.B.—It has been found necessary to substitute the term "Rideal-Walker Co-efficient" for that originally introduced by the authors, viz.. "Carbolic Acid Co-efficient," owing to the abuse of the latter on the part of unscrupulous manufacturers and vendors.—Vide British Medical Journal, April 6, 1907.

#### Preparations of Cyllin;-

Cyllin Capsules (palatinoids)—Recommended for Gastric or Intestinal Antisepsis.

Cyllin Syrup-For use where indicated in Infantile Diarrhoea.

Cyllin Inhalant—For use with Cyllin Inhalator in suppurative conditions of the bronchial passages, &c.

Lano-Cyllin-For use in Eczema, Pruritus, and other Inflammatory conditions of the Skin.

Cyllin Pastilles—Antiseptic Throat Lozenges; invaluable for purposes of mouth hygiene.

Cyllin Obstetrical Lubricant, Soaps, Lint, Dusting Powder, etc.

See Pamphlet entitled "Standard Chemical Disinfectants." Copies, together with working Samples, sent gratis and postage paid on applying to

Jeyes' Sanitary Compounds Co.. Ltd., 64 Cannon Street,

By Appointment

to H.M. the King.

# Influenza?

The present mild outbreak of "influenza," in which gastric and intestinal symptoms are prominent, may be combated to a large degree by efficient intestinal antisepsis. These symptoms are indisputably those of fermentation, of bacterial origin. It is not necessary that the influenza organism (Pfeiffer's bacillus) should reach the gastric and upper intestinal regions to effect such troubles, as the devitalising influence, produced generally by the growth of this bacillus in any part of the body, affords free opportunity for the untrammelled activities of certain intestinal organisms which in health remain in a state of inhibition, or at least fail to assume pathogenic powers.

# Cyllin Palatinoids

are accordingly indicated as a direct and reliable preventive measure.

Cyllin Inhalant as an auxiliary agent may be relied upon to supplement the action of Cyllin Palatinoids in the respiratory tubes, more especially the naso-pharynx, pharynx, and upper larynx. To be used pure in special Inhalator.

See Pamphlet entitled "STANDARD CHEMICAL DISINFECTANTS." Copies, together with working Samples, sent gratis and postage paid on applying to

Jeyes' Sanitary Compounds Co., Ltd., 64 Cannon Street, London, E.C.

### Notes and Comments.

Appendicitis. and Corsets THE ætiology of disease is one of the most difficult parts of medicine, and the exact causation of many maladies is a subject of great doubt to medical men. To the gentlemen

who write for newspapers, both in the editorial and advertisement columns, there are no such hindrances to knowledge, and the cause of disease may be either evolved out of the writer's inner consciousness on the spur of the moment, or a theory may be obtained at equally short notice from the proverbial well-known Harley Street specialist. After having invented a cause, the next process is to continue to harp on it till the public are convinced of its truth, and when this desirable end is accomplished comes the final stage, in which the journalist triumphantly upsets the theory, and shows how wrong the public have been all the time. An instance of this entertaining game has been going on of late. Some quill-driving pathologist discovered that the wearing of corsets was the cause of appendicitis, and good ink and paper were wasted in the crusade of impressing the world with the momentous fact. Finally came the débacle in the shape of quotation by a weekly paper of some remarks made by Dr. John B. Murphy, of Chicago, who pointed out the fact that as appendicitis is four times as common in men as in women, corsets could not be an ætiological factor. We can only trust that this will lay that ghost for the time being.

THE British Dental Association are "Hygienic fortunate in being armed with a Institute" in better instrument for offensive purposes than the Medical Act, and they are showing creditable activity in availing themselves of its provisions for the suppression of unregistered dental practitioners. amusing and interesting prosecution took place at their instance at Bishop Aukland on the first of this month, when the local manager of a business calling itself the "Hygienic Institute" was summoned for unlawfully representing himself to be a duly qualified and registered dentist, contrary to the Dentists Act, 1878. For the purposes of obtaining evidence, two policemen, disguised as working men, had gone to the Institute, and one of them asked for the dentist. The manager came forward, and when asked, "Are you the dentist?" replied, "I am." The constable then consulted him about a tooth, which Smith, the manager, advised him to have pulled out at the cost of a shilling. In an adjoining room into which he was shown was an operator who injected something into the gum, and pulled out the tooth while Smith held the patient's head. There is something

irresistibly comic in the idea of a policeman going to collect evidence against an unregistered dental practitioner, and in his devotion to duty going so far as even to allow one of his teeth to be extracted. Or did he, we wonder, take this as a favourable opportunity of getting a troublesome tooth pulled out at the expense of the county funds?

As, however, the tooth came out in due course, and the constable de-Fines, Damages, and clined to have a second one extracted, Appeals. it may be that it was really professional zeal that prompted the heroic act. The manager being called to give evidence on his own behalf, admitted that he had only been in the business about a year, but, with some reluc-tance, admitted that prior to this he had been a traveller for a firm of wholesale fruit merchants! The Bench found him guilty of a breach of the Act, and fined him £5 and £3 13s. costs, declining to allow an appeal on the question of fact, but agreeing to state a case on the point of law. Even more unfortunate was the Institute at Cardiff, for there a civil action was brought against them for £100 damages for the alleged ignorance and unskilfulness of the persons in their employ, with the result that the jury awarded the plaintiff £60, though here, again, an appeal was granted. It is an interesting fact that though the public are so ready to prosecute medical men whom they suspect of having injured them by lack of care or skill, yet they seldom seek redress from unregistered or irregular practitioner for the same offence. It would seem to follow as the night the day that an unregistered dentist has, legally, not sufficient skill to practice dentistry, and that, therefore, any person who consults him, provided there was no false representation, has only himself to blame.

Poor-law but almost necessary type, in which Regulations and Emergency. patient without his fee being guaranteed, has occurred at West Hartlepool. It seems that an unknown man was taken ill in the street, and, after being carried into a neighbouring house, the police were informed by

a neighbouring house, the police were informed by a bystander. The superintendent of the police then telephoned to the Poor-law medical officer, requesting him to attend, and the doctor asked if the police would be responsible for his fee. Being told "No," apparently he said he would not attend without an order, but almost immediately afterwards a message arrived that the man had died. An inquest was held in due course, and these facts were stated in evidence, and the jury, after finding that death was due to apoplexy, added that they desired to express

their disapproval of the conduct of the parish doctor in refusing to attend without his fee being guaranteed. It is most unfair that in cases such as this private practitioners should be made the scapegoats of a thoroughly bad system. As parish medical officer, the doctor can only attend on an order, and consequently any service rendered has to be given in his private capacity. The police refused to be responsible for his fee and did not send their own surgeon, who, presumably, could have charged a fee. It is invidious in the extreme that medical men should be placed in such situations and made to bear the brunt of the meanness and short-sightedness of local authorities.

South-West London Inquests. MR. TROUTBECK seems to carry on the process of conducting inquests on patients who die after operations, though, considering the number of large hospitals and infirmaries in his

districts, it is difficult to know on what principle he appears to select deaths at the Bolingbroke Hospital for his special attention. Also, it would also be interesting to learn at what period after an operation a patient may die without his relatives incurring the unnecessary pain and distress of an inquest, If, as Mr. Troutbeck maintains, an operation is an "accident," presumably the law as to length of time pertaining to deaths after accidents applies to deaths after operations, in which case the time of his courts would be pretty well filled up in inquiring into all such cases. Indeed, if Mr. Troutbeck is sincere in his view and abides by his own interpretation of the Coroners' Act, he should at least be consistent. We have no definite information as to how many of these deaths are really made the subject of inquests, but from the number reported we judge them to be few and spasmodic. If we are correct in this conjecture, it is neither creditable to Mr. Troutbeck's sources of information nor to his determination. It seems to us that there is a hiatus, a gross hiatus, and that it should be bridged over.

Evidence Thereat. We note also that the person selected to perform the post-mortem is still Dr. Freyberger, and that he is called upon to tell the jury the cause of death. Now, although the surgeon

death. Now, although the surgeon be also called, it is plain that Dr. Freyberger's knowledge of what took place at the operation is simply hearsay, and although the coroner's court is a law unto itself, it is pertinent to point out that such evidence is rightly regarded as worthless in every English court of law. If Mr. Troutbeck insists on having a "special pathologist," it would be as well to confine his evidence to facts actually noted by himself and to deductions drawn from those facts, uninfluenced by what may be told him by others. In the report of a case before us, in which a patient had died after an operation for cancer of the bladder, Dr. Freyberger is reported to have said: "Death was caused by sudden failure of the heart in consequence of the shock of a prolonged operation, while the deceased was suffering from the effects of cancer." And, again, in another case he is reported as having said: "Death was due to heart failure in consequence of collapse caused by the gangrenous state of the bowel. He could not entirely dissociate from the death the shock caused by the anæsthetic."

Legal Purism. WE have never maintained that the advice of a recognised pathologist might not be usefully sought in a certain class of cases of pathological difficulty. Such difficulty, of course,

did not exist in these instances, and there was no

need for a pathologist. In both cases the operating surgeon was called, and his evidence as tothe cause of death and the necessity of the operation would far outweigh in value that of a pathologist. In fact, Dr. Freyberger's evidence was totally unnecessary, and if he had confined himself to facts observed would merely have been unnecessary. When, however, he says that an operation is a "prolonged" one, it is obvious that he is speaking of facts outside his own knowledge, and when he says that gangrenous bowel has been a cause of death, when the gangrenous bowel had been removed at the operation, it would seem that he is doing so again. Mr. Troutbeck holds himself out as a lawyer and glories in his interpretation of the law, though most other people, including the late Lord Chancellor, think he is mistaken. But obviously if there is any value in a special pathologist's evidence, it is confined to a strict adherence to facts within his observation, and if the reports before us are at all correct, even this elementary legal maxim is disregarded in this court of law.

#### LEADING ARTICLES.

THE QUACK MEDICINE PERIL.

For years past the question of infantile mortality has been pressed upon the public attention. In season and out of season the matter has been discussed from every possible standpoint, and the community have been very properly educated upon the preventability of much of the yearly "massacre of the infants," as it is termed by a certain class of journalists. Nor can it be doubted that much good has arisen from the agitation. Such topics as the proper eeding of infants, the special dangers of infantile maladies, the need of isolation in infectious disorders, and the bearing of tuberculous milk upon tuberculosis in children have all been brought home to parents by a thousand agencies, voluntary and official, in all parts of the kingdom. One most important addition to our comprehension of the whole subject has been the demonstration by Alderman Broadbent in Huddersfield, and by practical philanthropists elsewhere, that given an additional incentive in the shape of a premium, the infantile mortality of a given district could be materially reduced. It would be difficult to devise any more absolute logical test of the preventability of a large percentage of the infantile death-rate in a modern town population. Curiously, the share taken by quack medicines in the needless destruction of child life has not taken the prominent place in the public attention to which, in our opinion, it is justly entitled. It seems more than likely that the facts of the case can only be brought out with anything like sufficient fulness by the agency of a Royal Commission. The unchecked existence of so grievous a drain upon the life of the country presents an extraordinary contrast to the zealous. care with which life is protected by the State in other directions. If it be desirable to protect the health of the community and to reduce mortality to its lowest possible ratio, then it

becomes at once imperative to control so injurious and destructive an agency of mischief as that inflicted by the sale of secret remedies. State, however, which tacitly permits the sale of nostrums for children by anyone who pays the stamp duty, exercises no greater care over adult citizens. The terrible injury wrought by patent medicines was fully revealed in the recently issued report by the Australian Government Inquiry. The facts demonstrated therein apply with equal force on our own side of the globe, for the operations of the advertising nostrum vendor are world-wide as his capital is unbounded and his cynical disregard of all interests but his own is unparalleled. Sooner or later the legislature will have to be compelled to turn their attention to the matter, and we have consistently maintained in the columns of THE MEDICAL PRESS AND CIRCULAR that the best way of going to work would be by way of Royal Commission. The suggestion deserves the close attention of members of the medical profession, who are daily brought face to face with the evils arising out of the traffic in patent medicines, and who are capable of exerting in the aggregate a potent influence upon the mind of the nation. Were all medical practitioners, for instance, to advocate strenuously that in future every patent medicine should bear on its label a statement of its ingredients, a flood of light would be thrown upon the nature of a trade that can thrive only in secrecy. Were such a condition enforced by the legislature, this nefarious trade would receive a deadly blow which would infallibly deprive it of a vast deal of its powers for mischief. The practical Germans, with their inherent love for hard-headed social legislation, have long ago adopted this simple plan. In Germany the purchaser of a patent medicine knows the exact composition of the stuff he is buying. What a contrast from the state of affairs in the United Kingdom, where poisons and injurious drugs are sold wholesale for the "cure" of a thousand different complaints under the ægis of a government stamp! Short of legislation we have long claimed that the police have ample existing powers to check the sellers of nostrums professing to cure hopeless maladies as locomotor ataxy, cancer, and so on, or to "cure" fifty complaints with one remedy, and that often of a worthless nature. The short and simple plan of prosecuting such gentry for obtaining money under false pretences would possibly obviate the need of special legislation. We commend this view of the matter to Mr. Herbert Gladstone, in the hope that he may find time to enforce some such policy in the important Government department over which he presides with dignity and distinction. No statesman could find a more solid and permanent claim to the gratitude of the nation than that which will be due to the Hercules who sweeps clean this Augean stable of quackery.

THE STATE AND THE MOTHER.

THERE are few subjects of more general interest or of keener controversy than the falling birth-rate. Of the fact that families are becoming more limited in numbers there is, of course, no doubt. Not only does this obtain in Great Britain, but in all civilised countries where proper statistics are kept, the same phenomenon is shown. We omit from the term "civilised countries" dominions such as Russia, where a condition resembling mediæval barbarism reigns wholly or partially. The fashion is to deplore this fall and to prognosticate all sorts of woes, degeneration, decline, and national extinction for the populations so affected. The other side of the question is that, generally speaking, where the birth-rate is high the infant mortality is large, and where the birth-rate is low the infant mortality is low. Without arguing about the causes of these phenomena, the desirability of one state of things, or the undesirability of the other, it is pertinent to observe that since the British birth-rate shows a tendency to fall, the duty of preserving infant life is correspondingly important, even if no question of morality or duty comes in. It will hardly be a matter for dispute that the path to prevention of infantile deaths lies through the mother, and whether by education, legislation, subsidy, or what not, so long as the value of home life and home influence continue to be regarded with the just veneration which they command at the present day, the State mother solution will be put aside in favour of the fostering of the natural or home mother. State care of the pauper, as represented by the guardians, has not been so brilliant a success as to invite one to attempt to construct the municipal crêche, with the municipal wet-nurse to take the place of the domestic hearth and the "own" mother. Difficulties in the way there are in battalions. The mother may be educated to the duties of motherhood; she may be lectured to, demonstrated to, and rounded up by health visitors, who, being estimable ladies with no children of their own, are reckoned to be better able to instruct working-class mothers than women who have had the nurture of a numerous progeny. Without decrying these efforts, indeed, while according all praise to the good they contain, we naturally ask if, supposing education of the mother be raised to university pitch, the question of infantile neglect and mortality would be solved? To that question there can be but one answer. Where maternal ignorance kills its hundreds, maternal inability to carry out the counsels of perfection in which she is instructed slays its thousands. It is easy enough to tell a mother to feed her infant every two or three hours, to give him as much sleep as possible, to train him into habits of regularity, to keep him constantly warm, and so on; but when a month after her confinement a mother has to go out to work for ten or twelve hours a day, advice of this kind is like sounding brass and tinkling cymbals. The real fact is that the mother should never go out to work, and that she should not be made to do more than is consistent with whole-hearted devotion to her baby. Theoretically, a working-man in full employment, even with a fair-sized family, should earn enough to keep things going, but practically the necessity of mothers going to work is

frequently very great. When the husband is ill and when he is unemployed, the wife has to go out if the mouths are to be filled without recourse to the Poor-law; widows with young children have to support their families by labour; and in some households the expenses are so large that the man's earnings have to be supplemented by the woman's. In poor neighbourhoods these circumstances are the commonplaces of life, and while such occupations as office-cleaning, charing, and many kinds of the less-well-paid forms of labour are considered to be "women's work," the man has often to rely on his wife for help in times of poverty and stress. We believe this matter of the employment of mothers to be one of the most urgent and complicated problems of the day, and we certainly see no royal road to its solution. Mr. Robert Harcourt, M.P., has just introduced into the House of Commons a Bill entitled the Local Authorities (Necessitous Mothers) Bill, which seeks to raise the standard of motherhood, and to secure supervision lest the responsibilities of maternity be neglected. Mr. Harcourt endeavours to make pregnant and nursing mothers remain at home and abstain from heavy physical labour, and to enforce on them the advantages of suckling their infants. He seeks to co-ordinate the Public Health authority with the Poor-law authority in securing supervision of the mother combined with monetary relief, and to provide the necessaries of life to the mother during the time she is nursing. Wholly praiseworthy as is the Bill in intention, we do not believe that inspection of this type is good for good mothers, and we are sure that habitual recourse to the Poor-law authorities cannot, in the long run, be beneficial to the sense of respectability and self-respect. Yet the problem remains, and we should be infinitely glad if some Napoleonic brain would indicate a simple and practical method of dealing with it.

#### CURRENT TOPICS.

#### The Territorial Medical Service.

SIR ALFRED KEOGH, Director-General of the Army Medical Service, may be congratulated on the encouraging success that has so far been obtained in the attempt to place the Territorial Medical Service on a sound footing. The wave of enthusiasm which has created a great citizen army within a brief space of time has happily ncluded that most important branch of organisation which deals with the care of the sick and wounded in war. So far as the Metropolis is concerned a most satisfactory state of affairs is reported. The 3rd London Field Ambulance Corps, for instance, has reached its full establishment of 230, and last year's camp was attended by 159 members of the 185 then on the roll. The two general hospitals in connection with the London force are also complete. Good work of a similar kind has been done all over the country by the consolidated corps which the Medical Service now represents. In future warfare the efficiency of the medical arm will probably rank as one of the most essential features of a first-rate military organisation.

# Poor-Law Infirmaries and Medical Teaching.

THE bettering of the conditions of Poor-law infirmaries has been one of the not least remarkable features of modern social progress. However cold and repellant the workhouse and outdoor poor relief may be to inmates and recipients, a very different atmosphere pervades a modern up-to-date Poor-law infirmary. Everything is bright, cheerful and well appointed, good wards, good nursing, highly skilled medical attentionin a word, both equipment and maintenance are up to the level of a first-rate voluntary hospital. In this way a vast amount and variety of disease is dealt with under the best modern scientific conditions, and an unrivalled field is furnished for the purpose of clinical medical and surgical teaching. The ratepayers who furnish the lowest expenditure necessary to Poor-law infirmaries might with reason ask that medical education might be advanced thereby. In the long run it. is clearly in the interests of the public that every possible facility should be afforded to the medical schools in their efforts to turn out well-educated medical practitioners. The waste of clinical material under the present system is obvious, and has long since attained the dignity of an accepted truism. For all that, its virtues appear to be strongly overlooked in the many schemes for Poor-law reform that are from time to timelaid before the public. Possibly the Asylums may one day be induced to lead the way in organising a scheme for co-ordinating their vast hospital organisation with the teaching forces of the medical schools.

#### Death Under Chloroform and the Compensation Act. The question of the administration of anæsthetics

has cropped up under various guises in legal actions arising out of the Workmen's Compensation Act. One of the most recent decisions upholds a claimant who refuses to undergo a remedial operation, provided he can obtain the support of a single medical man in his objection to surgical intervention. Last week another decision of farreaching importance was delivered by the Master of the Rolls in the Appeal Court. Some time agoa Stalybridge man in the employ of the Calico Printers' Association, Ltd., met with an accident in the course of his employment. At a subsequent date he, while undergoing an operation, unfortunately died whilst under the influence of the chloroform. The County Court Judge before whom the claim for compensation was brought disallowed the application. On appeal, however, the Master of the Rolls said the County Court Judge had misdirected himself, for the step taken by the workman was not only courageous, but was, moreover, in the interests of his employers. The case was accordingly remitted to the County Court, not for the purpose of re-hearing, but to assess the amount of the compensation.

#### Proposed Legislation against Research.

The opponents of research by experiments on animals are making themselves active in the present

session of Parliament, no fewer than four Bills dealing with the subject having been introduced. Two of these have been brought forward by such "whole-hoggers" as Sir George Kekewich and Mr. Hodge, and aim at the entire suppression of experiments on living animals. Another, for which Mr. George Greenwood is chief sponsor, is much less far-reaching in its aims, and is directed toward imposing further restrictions as regards the granting of licences for research, and toward increasing the powers of inspection. This Bill, by a stroke of luck, came up in the early morning of the all-night sitting on the Annual Army Bill, and was advanced a stage. The fourth measure before the House is the Dogs Protection Bill of Sir F. Banbury, which prohibits under severe penalties all experiments on dogs. None of the Bills are likely to go far, and it was only by unusual luck that the Cruelty to Animals Bill came up last week.

# Administrative Measures against Tuberculosis.

DR. NEWSHOLME, the Medical Officer of the Local Government Board, has issued a valuable memorandum on administrative measures against tuberculosis. Its object is to supplement, from a medical standpoint, the information contained in the circular letter issued recently to all sanitary authorities by the Local Government Board. Dr. Newsholme wishes to direct activity in particular towards two ends-early recognition of the disease and the prevention of infection. As an aid to early diagnosis, it is important that practitioners should have vailable a free bacteriological examination of the sputum. Moreover, it is hoped, and with reason, that the medical inspection of school children will lead to an earlier recognition of many cases. For the prevention of infection various administrative measures are required. Of these the chief is the general education of the public and of school children in matters of hygiene, and more particularly instruction of those specially liable to infection by tuberculosis. To this class would belong not only those in close contact with the infected, but others like barmen, potters, cutters, hairdressers, who are most exposed to infection by reason of their occupation.

#### Unreadable Prescriptions.

THE illegibility of the prescriptions of medical men has become proverbial. So fixed is the characteristic that it must be accepted as significant of some determining condition of professional life. It may to some extent be due to long use of surgery pens of varying degrees of badness, and partly to the little care bestowed upon the mere mechanical act of writing by energies that have but recently emerged from the strain of determining diagnosis and treatment. But whatever the real origin, the outstanding fact remains that the handwriting of the average medical man is unutterably bad. Happily from long practice in its interpretation, the chemists can as a rule read what are hopeless hieroglyphics to the man in the street. The remedy is not easy to find. Possibly the General Medical Council might attach extra marks to caligraphy in the scheme of preliminary medical education, or insist upon production of evidence of capability to write legibly before qualification. In any case, it is clear that some extra precaution should be taken when a bad writer is ordering poisonous or otherwise dangerous drugs.

#### PERSONAL.

PRINCESS CHRISTIAN visited Purley on March 31st in order to open a Cottage Hospital built by subscriptions raised in the district. The High Sheriff of Surrey, Sir Frederick T. Edridge, welcomed her Royal Highness on behalf of the committee.

THE John Tomes Dentil Prize for 1906-1908 was awarded to Mr. Arthur Swayne Underwood, M.R.C.S., L.D.S.Eng.

SIR RICHARD DOUGLAS POWELL, M.D., was reelected President of the Royal College of Physicians of London by a practically unanimous vote, recorded on the 5th inst., at a Comitia of the College.

INSPECTOR-GENERAL JAMES PORTER, C.B., M.D., Director-General of the Medical Department of the Navy, has been appointed Honorary Physician to the King, in the place of Inspector-General Sir John Watt Reid, K.C.B., deceased.

AFTER two years spent in Central Africa investigating, on behalf of the Liverpool School of Tropical Medicine, means of checking the spread of sleeping sickness, Dr. Kinghorn and Mr. Montgomery have returned to England.

THE DUKE OF DEVONSHIPE has been unanimously elected President of the West End Hospital for Nervous Diseases, in succession to the late Lord Egerton of Tatton, and Mr. H. C. Willock-Pollen has been elected Vice-Chairman in the place of the late Mr. A. W. Elam.

THE Jacksonian Prize was awarded to Mr. J. P. Lockhart Mummery, F.R.C.S., for his essay on "The Pathology and Treatment of those Conditions and Diseases of the Colon which are Relievable by Operative Measures."

At the annual Graduation Ceremonial at the Unversity of St. Andrews, which took place on March 31st, the honorary degree of LL.D. was conferred upon Dr. James Wallace, D.Sc., M.D., F.R.S., Professor of Chemistry in the University of Edin burgh.

THE Radcliffe Prize for 1909 in the University of Oxford has been awarded by the Master and Fellows of University College, upon the report of the examiners, to Dr. Arthur Frederick Hertz, formerly Demy of Magdalen College. The subject of Dr. Hertz's dissertation was "The Physiology and Pathology of the Movement of the Intestines."

THE Lady Mayoress presided on the afternoon of March 31st at a drawing-room meeting at the Mansion House in connection with the Royal Institute of Public Health, for the purpose of calling attention to the need of hygiene in the home. Her Majesty the Queen and Her Royal Highness the Princess of Wales have consented to become patroness and vice-patroness respectively of the Ladies' Committee in course of formation.

At the last quarterly meeting of the Council of the Royal College of Surgeons of England on April 1st, Sir Shirley Murphy, Medical Officer of Health to the County of London, and Mr. G. Dancer Thane, Professor of Anatomy at University College, London, were elected Fellows of the College under the clause of the Charter relating to the election of members of twenty years' standing.

## A CLINICAL LECTURE

ON

# DUODENAL ULCER: ITS DIAGNOSIS AND SURGICAL TREATMENT. (a)

By JAMES SHERREN, F.R.C.S.,

Assistant Surgeon to the London Hospital, Surgeon to the Poplar Hospital for Accidents.

Part II.—(Concluded from page 348.)

Prognosis after Perforation.—Without operation, perforation of a duodenal ulcer is fatal in almost every case. With operation, the death-rate is much greater than in perforation of gastric ulcers. For example, in the past six years I have operated upon eleven cases of perforated duodenal ulcers, of whom eight died, and upon fifteen cases of perforated gastric ulcer, of whom seven died. The mortality figures for these two conditions at the London Hospital for the last ten years, which have been taken out by Mr. Milne, Surgical Registrar to the Hospital, show the same difference. Thirty-two cases of perforated gastric ulcer have been operated upon, with a death-rate of 67.4 per cent.: 42 cases of duodenal ulcer, with a death-rate of 80.9 per cent. A similar difference is shown in the figures given by Crisp English for St. George's Hospital for the years 1892-1903—42 gastric ulcers, with a death-rate of 42 per cent.; 8 duodenal, with a death-rate of 75 per cent. The high death-rate at the London Hospital is due to the late period at which many of these cases are admitted. In the district drained by the Hospital, medical advice and operation are put off as long as the patient thinks is possible. Mayo Robson collected 155 cases of perforated duodenal ulcers, with a death-rate of 66 per cent., but of these 61 were operated upon within the first 24 hours, whereas in the London Hospital cases 6 would be the outside number of early

To what can the difference in the mortality in gastric and duodenal ulcers be attributed. Considering that many of the cases of perforating ulcers of the duodenum are just at the pylorus, and produce a sudden onset of symptoms, I think it must be due to the relatively less severe symptoms in some cases, which render an early diagnosis less likely, particularly in ulcers situated in the second part or the junction of the first and second portions. The death-rate of the first group into which I divided the symptoms of perforating duodenal ulcer is the same as that of perforative gastric ulcers operated upon at the same time after perforation.

It is in the second group of cases in which the symptoms arise more insiduously, that diagnostic difficulties and consequent delays in resorting to operative measures arise. As the knowledge increases that all cases of sudden abdominal pain must be considered surgical, so the death-rate will diminish. As individual experience increases and attention is drawn to the difficulties, there is no doubt that even in hospital practice the death-rate will diminish markedly in the next few years. But the ideal state is to diagnose and operate upon these cases before perforation.

Turning now to the cases of chronic duodenal ulcer before perforation has taken place. What are the symptoms which are met with in these cases? Is it a condition easy of diagnosis? A vivid description of the symptoms in a typical case has been given by Moynihan, and I cannot do better than quote this. "The symptoms of duodenal ulcer are, in the great majority of cases, sufficient to enable a diagnosis to be made without any physical examination of the patient. The anamnesis is to this effect. After food is taken, the patient is free from pain, the period of an hour or two which follows a meal, is the best time of the day. At a time varying from 1½ to 4 hours after the meal, a sense of uneasiness is noticed in the upper part of the abdomen. A burning gnaw-

(a) Delivered at the Medical Graduates' College and Polyclinic.

ing sensation develops, and there is a bitter taste in the mouth, with it may be eructation of food or gas, bitter and acid in taste. The pain, which gradually increases, may be relieved, often considerably, by belching or by pressure. As it increases in severity it strikes through to the back, to the right of the middle line, and it may radiate round the right side of the chest. As all patients discover for themselves, the taking of food relieves the pain. . . The more substantial the food the greater the interval of relief. If meat is taken in good quantity there will be a long period of ease; if only fluid foods are taken, the relief is short or not experienced at all."

If these symptoms are present I am in agreement

If these symptoms are present I am in agreement that the case is one of ulcer of the duodenum, but, unfortunately, such a typical history is by no means

always to be obtained.

It must, however, be pointed out that the mere fact that pain is present after food, relieved by a warm drink or by sodii bicarb. is not sufficient to enable us to diagnose duodenal ulcer. These symptoms must persist in spite of medical treatment, or recur after treatment. It must also come on at least an hour and a-half after food, for in some cases the pain in chronic gastric ulcer is also relieved by taking food or sodii bicarb.

All observers are agreed that pain is the most important symptom, pain coming on at a considerable interval after food, often waking the patient at night, and relieved by food. In many of the cases seen at the present time, when the ulcer has been in existence for years, vomiting is present, due to dilatation of the stomach, and in these late cases melana is often noticed, the patient giving a history of attacks of faintness, followed by the passage of blood. In only one of my cases was melæna the most prominent symptom.

To review now the 13 cases of chronic duodenal ulcer upon which I have operated before perforation occurred. Twelve were males, and of these nine were correctly diagnosed before operation, and fell into group two. These were all males, and although in no case was the history so typical as that I have quoted yet, it was sufficiently so to make the diagnosis evident. In all, pain coming on an hour and a-half to two hours after food and waking the patient at night was a prominent feature. Vomiting was not often met with unless dilatation of the stomach had supervened, and if met with did not often relieve the pain, although one patient induced vomiting in order to do so.

I have been struck in looking through my notes by the long period during which the patients had had symptoms, and in many cases had been treated

medically.

Out of the 13 cases, the symptoms had been present off and on for 12 years in one case, 10 years in two cases, 7 years in three cases, 5 years in two cases, 22 years in two cases, in two only nine months duration. Of these cases four had had melæna.

Of the 9 cases in which a definite diagnosis was possible, the pain came on more than two hours after food, or was said to have no relation to it. In six of these cases, the patient volunteered the statement that the pain was relieved by taking food, and that it woke him at night. In no case have I yet observed that the more solid the food the greater the ease. In all the patients in this group, there had been remissions of almost perfect health, and in several the symptoms had never been severe enough to make them

give up work. In many cases the pain was more to the right side than the left, but when dilatation of the stomach has supervened this is often masked by the symptoms due to this late complication. In one patient only, in whom the ulcer had been in existence twelve years, was there a history of jaundice, this came on three years after the commencement of the illness, and lasted a month.

Comparing these cases now with those of chronic gastric ulcer operated upon during the same period, cases in which the ulcer could be seen and felt. Out of 32 cases, 16 were women. In all except three the pain began within an hour of taking food, often within 15 minutes, and in all but two vomiting was a marked symptom, and relieved the pain. In 29 cases there was no suspicion that the ulcer had any other situation but the stomach. But in two cases a man of 42 and a woman of 37, the diagnosis was obscure, and

the suspicion was that it was doudenal.

II. S., æt. 44, was quite well until 2½ years before admission. He then noticed a sinking feeling in the epigastrium, followed by pain two and a half to three hours often food. This was a possible to the second transfer of the food. hours after food. This was relieved by lying down or taking a meal. This attack lasted six months, and then he had another of three months' duration, and free interval of five months, then an attack which lasted until admission. The pain was chiefly to the right of the midline, but when severe affected the left side also. He vomited on two occasions only.

had never had hæmatemesis or melæna.

He was a thin, rather sallow, man. The abdomen appeared normal, the stomach was not dilated, but there was a spot of deep tenderness one inch to the

right and above the umbilicus.

I considered this a case of duodenal ulcer. At the operation I found the duodenum perfectly healthy and free from adhesions, but there was a small saddleshaped ulcer on the lesser curvature of the stomach, midway between the pylorus and cardia. ulcer present and no scars. I operated December 2nd, 1908, and he went out free from symptoms on December 23rd.

In the next case, a woman, æt. 37, was admitted to hospital November 11th, 1908. At the age of 20 she had pain after food and vomiting; at the age of 22 she had hæmatemesis on one occasion. She then got almost well until the last three years, when she had been suffering from pain, coming on an hour and a-half after food, gnawing in character, and sionally waking her at night. The pain lasted till the next meal or until she took some sodii bicarb. No vomiting for years. Never any melæna. Has taken no meat or vegetables for years. In this case I diagnosed a duodenal ulcer, and thought that the original gastric ulcer had healed. The abdominal examination was negative.

The duodenum and anterior surface of the stomach were normal. On tearing through the meso-colon into the lesser sac, I came upon a hard mass the size of a shilling on the posterior wall of the stomach, close to the middle of the lesser curvature. I did a posterior no loop gastro-enterostomy, and she left hospital free

from symptoms 19 days later.

These two cases fall into the third group, in which the diagnosis between gastric and duodenal ulcer is impossible. Although a careful search was made, no trace of a duodenal ulcer was discovered. It must be remembered that these two conditions may co-exist, but, as Moynihan has pointed out, the gastric ulcer has usually healed. It must be a matter of great rarity for an ulcer to be diagnosed as gastric and turn out at the operation to be duodenal.

There still remains a group in which no symptoms indicative of a peptic ulcer exist; in these cases the patient is usually considered to be suffering from

gall-stones.

J. A., a Hebrew, æt. 30, was admitted to the hospital for attacks of pain, coming on irrespective of food, situated in the right hypochondrium, and of great severity. In addition to the sudden attacks of pain he had a constant pain in this region. He had never vomited or passed blood in the stools. He was sent to me with the diagnosis of gall-stones. The diagnosis evidently lay between this and duodenal

ulcer, and on the whole I inclined to the latter. At the operation I found a large mass in the second part of the duodenum, and did a posterior gastroenterostomy. He has now lost his pain and eats anything, but complains of some pain when he works.

In the next case the diagnosis was not at all evident.

H. P., a blacksmith, æt. 48, was admitted under my care, November 7th, 1908. For two years he had been suffering from epigastric pain, gnawing in character, varying in intensity, but gradually getting worse. It was not affected by food, never relieved by food, often waking him at night. The attacks lasted several waking him at night. The attacks lasted several hours, and during the last week the pain had gone to the right shoulder once or twice. Between the attacks he felt quite well. He eats anything, and had never had indigestion. He was a big, healthy-looking man. The abdominal examination was negative. I thought in this case that gall-stones was the most probable diagnosis.

On November 11th I explored and found the gallbladder healthy; on further search I found a hard mass on the anterior surface of the second part of the duodenum. I did a posterior gastro-enterostomy, and he left hospital free from pain and feeling quite well,

December 5th.

In both these cases the ulcers were in the second

part of the duodenum.

Passing the symptoms now in review. We can say that chronic ulcers situated in the first part of the duodenum can be accurately diagnosed in the majority of cases, that occasionally a gastric ulcer will be found where a duodenal ulcer was expected, that in all, the principal symptom is pain coming on a considerable time after a meal, often said to have no relation to food, at other times that it is relieved by taking food, often waking the patient at night. Vomiting is not a feature of the case unless the condition has led to dilatation of the stomach. Vomiting occurred in 11 out of the 13, but it was not a pro-Vomiting minent feature except in the cases I have mentioned. Difficulties arise in the cases in which the ulcer is situate in second part of the duodenum, or at the junction of the first and second parts. An effort should always be made to diagnose these cases early, and to investigate carefully every "dyspepsia" occurring in men of adult age, so as to avoid the desperate condition of perforation.

Treatment.—It appears probable that a duodenal ulcer does not heal except as the result of operation. If the condition is diagnosed, operation should be undertaken without delay. While in cases of chronic gastric ulcer, medical treatment should be thoroughly tried, I believe that it is useless when once a duodenal ulcer is present. Posterior gastro-enterostomy should be performed in the pyloric segment of the stomach, so as to preserve the normal functions of the stomach as far as possible. Gastro-enterostomy is an operation associated with very little risk. Since 1904, I have done sixty operations of this nature in simple conditions of the stomach without a death. Moynihan and Robson have recorded much longer series of cases

without a death.

The prognosis after operation is extremely good. I know of no condition, apart from chronic gastric ulcer, in which the relief is so striking, and the patients are free from those minor inconveniences which sometimes trouble after a successful gastro-enterostomy for gastric ulcer.

I have traced the after-history of all my patients. One case died, the first done in 1904. This patient died of broncho-pneumonia, five days after operation. This patient At the post-mortem examination, the anastomosis was perfect and the abdomen normal. The pathologist's diagnosis was "aspiration broncho-pneumonia."

Of the other cases, all have lost their symptoms, and in only one, the patient already mentioned, is there even discomfort. All surgeons report the same results. Mayo reported 175 operations with two deaths, of these patients he could trace 103, 93 of these were cured. Dr. E. B. Leech reports that of 6 cases of duodenal ulcer operated upon at Manchester Royal Infirmary, one died, and of the remainder, four were cured, one nearly so.

We have, then, in gastro-enterostomy a cure for duodenal ulcer, a cure which should not be left too

long before it is applied.

The question will arise as to surgical treatment during an attack of bleeding from a duodenal ulcer. Every case must be freated on its merits, no patient should be allowed a second attack of bleeding. I think that it rarely is necessary to operate during the attack, but if, in the opinion of those in attendance, the bleeding, if not rapidly arrested, will prove fatal, or the recurrence of the hæmorrhage be fatal, immediate operation will be advisable, and it may be necessary to open the duodenum and directly secure the bleeding point.

I have only been called in once to see a case in which there was severe hæmorrhage from a duodenal ulcer at the time of the bleeding in which the question

of immediate operation arose.

S. B., æt. 30, was admitted to a medical ward in the London Hospital, May 19th, 1905, with a history of ten years' indigestion. He had had many attacks of pain coming on two or three hours after food, sometimes accompanied by vomiting, but the vomiting never relieved the pain. He had never had any hæmatemesis, but his motions had been black. Three days after admission he was seized with an attack of giddiness, and passed 16 oz. of blood per rectum, and about the same amount on the following day. The next day he had another fainting fit, and then vomited blood. When I saw him the bleeding had ceased, and I dea large ulcer at the junction of the first and second parts of the duodenum. I did a posterior gastro-enterostomy, and he left hospital 28 days later. I saw him four weeks ago, fat, of a good colour, and without any pain or discomfort after food.

In conclusion, I would urge upon you the desirability of solutions and the colour is due.

bility of early diagnosis and early operation in duodenal ulcer, before serious complication such as per-

foration or bleeding occur.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Andrew Fullerton, M.D., F.R.C.S., Hon. Assistant Surgeon to the Royal Victoria Hospital, Belfast, and the Belfast Hospital for Sick Children. Subject: " Renal Calculus."

#### ORIGINAL PAPERS.

#### THE PREVENTION OF BLINDNESS DUE TO OPHTHALMIA OF THE NEW-BORN.

By N. BISHOP HARMAN, M.A., M.B.CANTAB., F.R.C.S.Eng.,

Lecturer in Ophthalmology, West London Post-Graduate College Assistant Ophthalmic Surgeon, West London Hospital; Ophthal-mic Surgeon, Belgrave Hospital for Children; Chief Clinical Assistant, Moorfields Hospital; Coulist, London County Council Blind Schools.

THE body politic, or the State, has done no greater honour to the medical profession than that which it has done in placing the national health in the protection of that branch of the profession controlling the public health departments. The recognition of the fact that modern medicine aims as much at the prevention of disease as at the relief of suffering is one of the greatest tributes that has been put to the credit of our art.

In these days we are as much in earnest in improving the physical possibilities of the children, and therefore of the race, as we are in the prevention of disease, for the one conduces to the other perhaps as much as the direct attack on the sources of infection. In all directions strenuous efforts are being made to improve the chances of happy and successful life for the coming generation, and the success that attends our efforts in guiding the energies of public-spirited lay workers to a fruitful result, will measure the degree of the continuance of the confidence that has been

reposed upon us by direction of the State in the many enactments that are written in the books of the law of civilised States.

Great things have been done, and yet much remains to be done. A very little acquaintance with certain of our public elementary schools will show that there are blots upon our success in the prevention of disease that should engage our earnest attention.

BLIND CHILDREN. For the past six years, by the direction of Dr. James Kerr, Medical Officer for Education of the London County Council, I have had the oversight of the Schools for the Blind and Partially Blind which form a part of the Special School system of the County. During that time I have examined over 400 children, noting the condition of their eyes, the degree of blindness and determining by every means in my power the cause of the blindness. The conditions affecting the eyes of these children are many, but by a very little arrangement it is possible to group them so as to show how heavy is the toll of blindness arising from certain

particular diseases. The figures which I arrived at and published recently in a little book, may be summarised as

follows: -

Inherited syphilis: (Interstitial keratitis, uveal disease, and optic atrophy)	6.36
Inherited syphilis:  (Interstitial keratitis, uveal disease, and optic atrophy) r  Optic atrophy, various causes	
(Interstitial keratitis, uveal disease, and optic atrophy) r. Optic atrophy, various causes	- 60
Optic atrophy, various causes	- 6-
	7.60
Macula damage	9.36
	1.38
Retinitis pigmentosa	1.38
Purulent ophthalmia	2,20
	0.82
Sympathetic ophthalmia	2.75
Trachoma	0.55
Phlyctenular keratitis	1.95
Congenital defects:	),
(Cataract, high myopia, microph-	
thalmia, buphthalmia, colobomata of	
iris and uvea, albumin, hydroce-	
phalus, etc.) 2	5-34
a effective and a second secon	0.27
<del></del>	

At the head of the list is the maximum percentage produced by one form of inflammation of the conjunctiva, and one that acts for only a very short period of the life of the subject. 36.36 per cent. of the blindness is due to the effects of the ophthalmia of the new-born

Great as this percentage is, it is in reality greater for, by careful attention and operation, some of the cases which figure in the list under those headings have been relieved to such an extent that they will escape from the category of blind; and then, by the exigency of official arrangements, the high myopes, who are not blind, but for whom an ordinary elementary school curriculum would be injurious, are collected in these schools. If all those who, in later years, would pass as bad-sighted, and not as blind, were eliminated, the percentage of blindness from ophthalmia neonatorum would exceed 40 per cent.

The figures obtained from the London County County

cil schools can be paralleled by those from any other country examined. Reinhard debited Germany, Austria, Denmark, and Holland with 40 per cent.; Claisse gave Paris 46 per cent.; Magnus gave Breslau 34 per cent.; and Katz gave Berlin 41 per cent. as blind from this cause.

INCIDENCE OF OPHTHALMIA NEONATORUM.

To obtain some indication of the incidence of the disease amongst the population generally, I have made two sets of inquiries: (1) A London district was selected, a suburb containing a fair average of London population. The practice in the district would be known as "Mixed." Half the population live in tenements, the other half in houses rented from £30 to £80 per annum, but there are few at the higher rental. At the lowest estimate, three-quarters of the children living in the district attend public elementary schools. I saw many of the doctors in private practice in this

neighbourhood and inquired their experiences of purulent ophthalmia in the new-born. I have now statistics of 15,000 live births. Amongst these the incidence of of injury to the eyes of infants from the disease averaged 0.047 per cent. Roughly, it may be said that of every hundred children born one contracts the disease and of every 2,000 born one is blinded or partly blinded by the effects of the disease. (2) As a check to this inquiry I examined the returns of the examination of the vision of children attending elementary schools in London, and found that one child in about every 4,000 showed the effects of the disease. It must be remembered in comparing the results of these two inquiries that no allowance is made for the death of affected infants, and according to Lobenstine and Harrar, of New York, children born of gonorrhœal mothers are less viable than those born of healthy mothers.

CENSUS OF THE BLIND.

In examining the Census returns of England and Wales for 1901, in a population of 32,527,843 souls, as many as 25,317 were returned as blind. Of these, 4,621 were returned as being blind from childhood, or one person in every 7,000. Of those blind from childhood, it is, of course, not possible to say with certainty the cause of the blindness, but those with experience of blind schools and asylums will not hesitate to agree that the conditions found in the London schools may be applied to the whole population. This would mean that in 1901 there were living 1,000 to 2,000 persons who were blind from purulent ophthalmia occurring at birth, and whose blindness

might have been prevented.

For a moment I might call attention to the seriousness of the loss which this means to the community. Let sentiment alone, and neglect the thought of the deprivation for so many of the chiefest joy of sense, and the greatest aid to freedom, usefulness, and pleasure. Consider only the cost of these damaged and the greatest and to treedom, userumess, and pleasure. Consider only the cost of these damaged folk to the community. Mr. Foulerton, the Medical Officer of Health for Surrey, in reviewing my book wrote:—"It may be pointed out that, accepting Mr. Harman's lowest estimate of 1,000 of the population blind from this cause, the cost of their maintenance must amount to over £50,000 per annum (the actual amount is probably nearly twice that sum), apart from the loss to the State of the services of so many workers." When we look into the accounts of the cost of providing education for the children in the elemenof providing education for the children in the elementary schools, and compare the cost of the normal child with that of the blind child, we are not surprised at Mr. Foulerton's estimate.

THREE CLINICAL POINTS.

I do not propose in this place to discuss the clinical aspect of the disease. Only on two points will it be worth while to revert to certain clinical features.

1. What is the cause, or most frequent cause, of the condition usually known as ophthalmia neonatorum? It is quite easy for anyone with a rudimentary know-ledge of bacteriology to satisfy himself of the com-moner infections that underly the purulent discharges of infants. For all practical purposes the micro-scopical examination of suitably stained film preparations of the pus form a sufficient diagnosis; and the conditions of staining are: that one be treated with an aniline dye such as Loeffler's methylene blue, and the other by the useful Gram's selective process.

A careful examination of large numbers of cases of purulent discharge in the new-born has shown that so per cent. are due to inoculation of the eyes at or about the time of delivery with the gonorrheal virus, the micrococcus of Neisser; and these are the cases that are dangerous to sight, for they produce the severest and most destructive form of inflamination, and consequently endanger the integrity of the cornea. The remaining 20 per cent. are cases of milder order, and are due to accidental inoculation with the Koch-Weeks bacillus, the colon bacillus, or the pneumo-As I have said, film preparations form a COCCUS. sufficiently accurate means of detecting these organisms in discharges from the conjunctiva.

2. Is the disease a danger to the members of the community other than the infants affected?

It is necessary to estimate the risk which these cases present to the community at large, for our view of the possible bearing of certain legislative enact-ments will be influenced thereby. It would be pos-sible to cite instances, and not rare instances of attendants on these children who have contracted the disease from their charges and whose sight has been seriously damaged thereby, but these cases are not talked of too much, they have a tragic side. Let me cite by way of evidence the following:-On one day at Moorfields Hospital I saw a mother and three girls, aged ten, eight and four years, and an infant of four weeks. The baby had developed ophthalmia neonatorum on the fourth day of life, a week later the youngest girl contracted the disease, a few days later the second caught it, and subsequently the eldest girl; and at the time they were seen the four children had the disease, and the mother showed the initial symptoms of an attack. Further, it was found that each of the children suffered from a gonorrhœal vulvitis. Such a series of secondary infections demonstrates more forcibly than any argument the risk of such a disease to the community at large.

3. What class of the population are most affected by the disease? I can best answer this by giving my experience at the Belgrave Hospital. For many years it was situated in Pimlico, and tended a small but very poor district. Amongst the infants under the age of 12 months, 34.4 per cent. were suffering from the ophthalmia of the new-born. In the new hospital at Kennington the patients are more numerous, and, on the average better kept. Of the infants under the age of 12 months that have attended here, only 6.2 per cent. were the subject of the disease. It is evident from these figures poverty and neglect tend to increase

the liability to the disease.

PREVENTION OF THE DISEASE.

Long before the microbic origin and the essential contagiousness of the disease had been determined, some sage observers came to conclusions as to its nature, and the precautions to be taken for its preven-

tion, that cannot be bettered to-day.

To Gibson, of Manchester, belongs the credit of first pointing out what should be done to stay the ravages of the disease. He wrote in 1807, giving three directions :

(1) The leucorrhœa of the mother ought, if possible, to be cured during pregnancy.

(2) When this has not been done, the noxious secretion ought to be removed from the vagina during delivery.

(3) The infant's eyes ought, immediately after birth, to be cleansed with a fluid which either removes the noxious matter, or is able to prevent its injurious effects.

No directions could be better. many would not believe in the true contagiousness of the disease. Stellwag, writing in 1860, recommends, for the prevention of the disease, "to keep the child away as far as possible from all dazzling light."
Cleanliness is of little count in his mind, and he repudiates the idea of inoculation from maternal discharges. The discovery by Neisser of the organism responsible for the most serious form of the disease justified Gibson and his preventive methods, and thenceforward there came the general introduction of regular practices of cleansing the passages of the

mother and the eyes of the child.

The name of Credé is particularly associated with the modern practice of prophylaxis. In his earliest publication he lays stress on the necessity for the dis-infection of the vagina, and the subsequent cleansing of the eyes of the child with an antiseptic solution. Gradually attention became focussed on the child's eyes. That the organism in question could be easily destroyed was shown by Piringer. He found that pus from an acute case of the disease might be inoculated into the conjunctival sac without injury, provided it was well washed out with water not later than three minutes after the inoculation.

Credé ultimately recommended the instillation of a 2 per cent. solution of silver nitrate into the eyes of the child immediately after birth. The benefit of the measure as applied in certain lying-in institutions is

beyond doubt. In Credé's clinic in Leipsig, prior to the use of this prophylaxis, the average incidence of the disease was 10.8 per cent.; after its use the incidence fell to between 0.1 and 0.2 per cent., and under similar conditions as good results have been obtained

Such results as these are very striking, and it is no wonder they have elicited much enthusiasm from those who know how much of the blindness found in our asylums is due to this one disease. From the recognition of the boon such a method may be under certain conditions, it is but a short step to suppose that it could be of equal value were it carried out under all conditions. Accordingly, it has been proposed that the method of Credé should be made compulsory by law-that is, that the eyes of every child should be treated with silver drops as soon as it has been born.

Such a proposition as this could not be made without exciting discussion, and there has been plenty of it, both at medical society meetings and in the medical

To sustain an argument for compulsory prophylaxis, two points must be made:-

(1) That there is a general or fairly general liability to the disease.

(2) That the prophylaxis is a certain preventive of the disease.

The first proposition is absurd. It can only be held by men who work so long at certain classes of disease that they become so obsessed by the disease that they consider all contaminated thereby. But the disease is not like small-pox, to which all unprotected are liable, be they clean or dirty, moral or immoral. It has at least for 80 per cent. of the cases a basis which proves a breach against the ordinary canons of morality held by the community. To brand the whole community because of a relatively few sinners would be as absurd as to damn with faint praise the pleasant lake of Windermere because we find on part of its leeward shore a filthy scum of froth and rotting weed and

But let us take a few figures. Of the 15,000 London births of which I obtained information privately, 12,000 were delivered by doctors who used no other prophylaxis than scrupulous cleanliness, and left silver or mercury solutions for the suspect cases. The incidence of the disease amongst these children was 0.72 per cent., and the injury rate 0.04 per cent. This compares very favourably with the best Leipsig results when Credé's method is practised.

As to the second proposition, the efficacy of the prophylaxis, we may admit that the use of silver nitrate drops of 2 per cent. is effective in cases where they are properly employed, but the usage may occasionally do direct injury to eyes, and, again, it may only cover slovenly practice.

There is a distinct body of evidence to show that

the use of the silver solution, or, for that matter, any germicide of sufficiently powerful effect, is not always innocuous to infants. Any such re-agent by its very nature is an irritant, and is liable to produce a transitory inflammation of the conjunctiva; this is a small matter when the effects are watched by skilled observers, but it would not be so if the usage became so prevalent and were placed in the hands of untrained, or partially trained, midwives; they would be likely to mistake the "silver catarrh," as it is called, for an initial sign of ophthalmia neonatorum, and probably increase the mischief by a further use of the germicide. I have seen this done, and with serious effects in weakly and ill-developed children.

Of the 15,000 private cases I have referred to, 3,000 were treated by the full Credé method, yet there were 1.2 per cent. of mild purulent cases, and o.1 per cent. of severe purulent cases, and in two cases, or 0.06 per cent., eyes were blinded. The figures for these 3,000 cases are not so good as were those of the other 12,000 of the same district where there was no routine use of germicides.

From these observations we may conclude: That Credé's method has done wonders in reducing the incidence of ophthalmia neonatorum in lying-in institutions, but it has not extinguished the ophthalmia, though the method is applied by experts and the

infants are under complete control. Further, special routine methods may be necessary in hospitals where there is a cumulation of sources of infection. experience of private practitioners, men who have carefully tried both methods, prefer strict cleanliness to a routine use of a germicide, reserving the germicide for suspicious cases; and in this they are following the dictate of rational medicine, and also the lines of prophylaxis, first suggested by Gibson.

At this point I might outline a course of procedure

for those who like rules.

1. Directly the head of the infant is born, wipe the eyes dry with clean, dry cotton wool.

2. As soon as the mother is settled, wash the eyelids of the infant freely with a simple lotion, then part the lids and run plenty of the clean fluid between them. For midwives, Condy's fluid is best, for the colour is impressive. The water used in the first bath of the child must not get into the child's eyes. At no time during the lying-in period may the mother's sponges,

napkins, etc., be used for the child.

3. If at delivery there be a suspicion of a purulent discharge from the vagina of the mother, cleanse the eyes in the same way, and wash thoroughly, then instil a drop of silver nitrate, 2 per cent., between the lids. The eyes must be re-examined and washed at the end of eight hours, and if there be any suspicion of discharge instil silver nitrate of r per cent., and no stronger, once in twelve hours, and wash with Condy every three hours. I lay as much stress on the washing as on the use of the germicide.

Recently an experienced lady doctor, a supervisor of midwives, asked me how I defined a "suspicious discharge" in infants, seeing that in most pledgets of mucus appear at the inner canthus by the end of the first twenty-four hours. My answer was to quote the words of the memorial to the President of the Local Government Board in 1884:—"If the child's eyelids become red and swollen, or begin to run with matter. . . . "

#### NOTIFICATION.

It is not enough to leave the matter here. Our present methods, even with the aid of the Notification of Births Act, do not give us effective control over the disease. It is still appallingly common to get children brought to the eye hospitals with the eyes irretrievably damaged within the first month of life.

Compulsory notification of ail cases has been suggested as the best means of controlling the disease. The idea is an excellent one. This manner of attacking a disease is not new and unfamiliar; it has the advantage of custom and use. Some diseases must be notified at all times; others are added or removed from the list as occasion and epidemics suggest. The Infectious Disease (Notification) Act of 1889 has worked with conspicuous success in the case of those diseases scheduled under the Act, but the ophthalmia of the new-born is not amongst them.

Notification of a disease is one of the first requisites to our knowing what is the true incidence of the disease. The tale of its effects we may know, but the number of cases from which these arise we do not know. So those who look to the compulsory use of a germicide must urge the necessity for notification as a preliminary to their demands.

I can best illustrate the advantages to be derived from notification by the following:—
In a series of 60 cases of ophthalmia neonatorum, 22

were first seen by me three or more weeks after the onset of the disease; of these 18 came with one or both eyes permanently damaged. The other 38 cases were seen in the first week of the disease; only one suffered any permanent injury to the eyes, and in this instance the parents lived twenty miles from the hospital and failed to bring the child for attention. The moral is clear—get the cases early and treatment will be a brilliant success. This is why we desire compulsory notification.

Notification is not only a controlling measure, it is of the highest educative value to the general public. It brings home to those most interested the seriousness which is attached to the disease by the authorities, and it is an infinitely preferable mode of education to such

wild-cat schemes as that proposed by Fieuzal, of Havre—that a booklet with warnings of the dangers of the disease should be given to those registered as just married; or the even more appalling proposition of Cohn—that the dangers of the disease should be explained to children in schools!

There are two objections to notification that I may

deal with here:

That the disease is essentially venereal, and that notification of the occurrence of the disease would be a hint of the "C.D. Acts." This objection disappears entirely when we remember that 20 per cent. of the cases of purulent conjunctivitis in the new-born are due to organisms other than the gonococcus. It is true that this is the most frequent and most dangerous

cause of the disease, but there are others.
2. The Infectious Disease (Notification) Act was drawn up, it is sometimes said, with the intent of protecting the public, and not to secure for the sufferers prompt treatment. The history of the family I have given, where the disease of the baby was communicated to the three elder girls and then to the mother, and ultimately produced a vulvitis in all the girls, is sufficient answer to that objection. The disease is essentially contagious, and is a danger to the community. It may not kill, but it certainly blinds.

#### SUGGESTED SCHEME.

Happily, no fresh legislation is necessary to make ophthalmia neonatorum a disease which must be notified. Under the powers of the Act of 1889 every local authority is enabled to add to the list of diseases the occurrence of which must be notified to it, subject to the consent of the Local Government Board. power has been fully used, and is increasingly taken advantage of.

The next concern is the machinery available for the treatment and oversight of the cases that may be notified. Here the difficulty is great owing to the overlapping and lack of co-ordination of the many health lapping and lack of co-ordination of the many health authorities. The medical officer of health of a district may not treat cases himself, but if he cannot do it directly, he can influence it indirectly. He can require the certification by a medical man that the case is being so treated as will prevent its being a danger to the community; and, failing that assurance, he could probably deal with the case as he would with a case of infectious fever—require the removal of the case of infectious fever-require the removal of the patient to a proper hospital or infirmary.

In the Midwives Act of 1902 we have already con-

trol in theory over a large number of those who conduct confinements; and as time goes on this control will be more effectual; but so far the arrangements do not permit of the oversight of cases occurring in their

Briefly, we should aim at:-

1. An exercise of the powers of the local sanitary authorities under the Infectious Disease (Notification) Act of 1889, to proclaim all cases of purulent ophthalmia occurring in children within twenty-one days of birth, notifiable by the attendant in whose knowledge they come, under penalties provided in the

2. The arrangement of such a plan as will enable the case to be promptly diagnosed by a medical officer skilled in the bacteriology of the disease: also to enable the case to be promptly and efficiently treated, ether by a private doctor, or by a doctor or doctors deputed by the Midwives Supervision Boards, or by a public hospital; or, failing these, to provide for the removal of the child to a Poor-law infirmary or such other convenient place as may be arranged, the mothers being provided for within the hospital for such time as necessary.

That the results of all such cases on the cessation of the disease should be notified to the medical officer of health for the district, for return to the Local Government Board, and subsequent publication with

the returns of infectious diseases.

I believe the working out of such a scheme as this would result in the almost total extinction of blindness due to purulent ophthalmia at birth, both by ensuring the prompt and efficient treatment of all cases of the disease, and also by educating the public to a sense of the seriousness sibility in the matter.

Conclusion. of the seriousness of the disease and their own respon-

In conclusion, I would urge the necessity for speedy action in this matter. With the extension of the Employers' Liability Acts, it will be increasingly difficult for the physically defective to obtain employment. Contracting out by the employers is not permitted, and the risks of employers are proportionately increased when a workman suffers so grave a physical defect as that of blindness. The scope of useful and remunerative manual work for the blind of ordinary ability is not wide, and there is difficulty even now in meeting the need satisfactorily. With the risks of employers liability pressing so heavily, the prospect of employment being found from philanthropic motives will steadily diminish, so that in some way or other the burden of support of the blind will fall on the State, either by the necessity for the provision of special workshops for them, or else by their drifting destitute and helpless on the poor relief funds. Public opinion would scarcely tolerate this latter condition, if the State by the extension of the employers' liability hinders the continuance of philanthropic effort which has been so successful in the past, the State will be compelled to take up the burden it has made impossible for private effort.

With such a prospect in view, it is indeed necessary for the State, if only from mere pecuniary motives, to do all in its power to prevent the occurrence of blind-

ness which is preventable.

# THE TREATMENT OF VARICOSE VEINS OF THE LOWER LIMB BY INTRAVENOUS INJECTIONS OF IODINE.

BY PROF. B. SCHIASSI, M.D., Surgical Tutor to the Faculty of Medicine of Bologna. [SPECIALLY REPORTED FOR THIS JOURNAL.]

In operating on varicose veins in the lower limb, I have often asked myself whether it was not possible to discover a means of dispensing with the necessity for the multiple incisions and innumerable ligatures

entailed by surgical intervention.

It has occurred to me that this might be done by turning to account an ancient practice which had for object to bring about the obliteration of the varicose veins by means of a chemical action provoked by substances introduced directly into the dilated vessels. But, before elaborating this idea, I had to dispose of the objection that has been raised to the principle involved in this mode of treatment—viz., that oblitera-tion of the veins thus induced by a process of thrombosis exposes the patient to the risk of the de-tachment of an embolus which may find its way into the general circulation and inflict irretrievable damage on some vital organ.

Personally, I am disposed to regard this risk of embolism as purely hypothetical. So far as I am aware, not a single instance in which a fatal embolus has been set free as the result of chemical phlebitis of a superficial vein has been observed, and, until it has actually occurred, I hold that it is extremely unlikely to happen, because, when we determine the chemical obturation of a vein by the irritating action of a non-necrosing agent, the obliteration takes place by a slow, gradual process of endothelial irritation followed by an increase in the number of young connective tissue cells which by-and-bye become adult and permanent. Under these conditions, the detachment of an embolus is hardly conceivable. Moreover, when we are dealing with the lower limb, the hydro-dynamical conditions in which the superficial venous pleaus of varicose subjects are placed, cause the circulation to be slowed down, and are distinctly unfavourable to the ascending displacement of embolic dibris. This argument is the more cogent seeing that Professor Bier, in some thousands of cases of varicose veins of the leg, thrombosed or not, has induced very active hyperæmia without having ever witnessed the slightest embolic manifestion.

Even if we admit, in the face of the evidence, that chemical thrombosis may give rise to embolism, the method of treatment employed by me provides an effectual guarantee against its occurrence, and need,

therefore, excite no apprehension.

Of the substances at my disposal I have selected the most irritating and the least toxic-viz., iodine. based my choice on experiments carried out by various observers, and on observations of my own on the intra-venous injection of iodine, previously undertaken with another object in view, which convinced me that it was likely to produce the effects I desired.

My procedure is the following: Having anæsthetised the skin by the injection of a few cubic centimetres of novocain, or under the influence of intraspinal anæsthesia, I make an incision two or three inches in length above or below the femoral condyle, accordin length above or below the remoral condyie, according to circumstances, and expose the saphena vein to that extent. This I ligature at the upper part of the wound, and at the lower angle I apply a pressure forceps to the vessel, which is then cut through near the ligature. This gives me an inch or an inch-and-a-half of vein. An assistant seizes the gaping vessel with a pair of forceps, and introduces a small glass the with a polivary and this is tied in position. tube with an olivary end. This is tied in position, and is joined at its free end with a piece of rubber tube, into which a large glass syringe is inserted. This syringe is previously filled with the following solution of iodine:

Iodine, 16 gr. Potassii iodidi, 23 gr. Aquæ dest sterilis fl. oz. iiiss.

The syringe having been joined up, the blood is allowed to invade and entirely fill the glass and rubber tubes in order to avoid the introduction of air bubbles. The injection is then made rather slowly, and directed towards the extremity of the limb. The injection is repeated until we have introduced from 30 to 50 c.c. (about an ounce and a-half) of the solution, according to the number and size of the varicosities and the dimensions of the limb. Then the vessel end is tied just below the glass tube, the end is cut off, and the small cutaneous wound is closed with two or three sutures.

As a rule, the patient does not complain of much pain during the intravenous injection of the iodised solution, though some subjects experience a burning sensation in the injected limb. When this is the case, the sensation may be obviated by injecting a solution of novocain, 25 per thousand, beforehand, but, in any case, the disagreeable feeling only lasts a few minutes.

I have never witnessed any disturbance, either local or constitutional, immediate or delayed, as the result of such injections, when practised of the strength and in the manner I have laid down. At most in the course of two or three hours the patient may present a slight rise of temperature (101-102.5° F.), and this subsides in a few hours.

The iodine injected infiltrates the whole of the superficial veins of the leg as far as the malleoli; a small quantity, indeed, passes vid the communicating veins

into the deep veins.

It is hardly necessary to describe the histological changes that take place in the walls of the veins consequent upon contact with the iodine, these having been thoroughly investigated by many authors. The interesting clinical fact is that six or eight days after the injection the greater part of the veins through which the iodine has circulated are transformed into hard cords perceptible on palpation, and are completely and finally obliterated. It follows that the passive hyperæmia which obtained in the domain of the superficial circulation of the leg is abolished, and varicose ulcers and eczematous patches due to the embarrassed local circulation improve and cicatrise.

This method has at any rate the merit of simplicity, and I term it the "minor means," because, by a very

and I term it the "minor means," because, by a very trifling operative act, we obtain a very striking result. I am convinced, as most of us are at present, I imagine, of the accuracy of Verneuil's theory of the deep origin of varicose veins, but in many cases it is necessary to get rid of the passive hyperæmia of the superficial plexus of veins in the leg, since this greatly assists the deep circulation. For instance the force assists the deep circulation. For instance, the force

which pushes the blood upwards, instead of being divided between the superficial and deep circulations, once the superficial circulation has been remedied, is wholly directed to the deep circulation increasing the rapidity of the flow, and preventing passive varicose

hyperæmia.

It is hardly necessary to remark that this treatment will not cure all cases of varicose veins, old-standing ulcers, and chronic thrombosis; indeed, it does not appear to me likely that any one method of treatment can prove successful in these various conditions. As, however, I have applied the method in some sixty cases, and have since been enabled to follow up the patients, I can recommend it with confidence.

#### STREPTOTHRICOSIS: WITH SPECIAL REFERENCE TO THE ÆTIOLOGY OF MYCETOMA. (a)

BY PROFESSOR MUSGRAVE, M.D., M.CH.

AND

MR. M. T. CLEGG.

BEFORE entering on a study of the ætiology of mycetoma, it is necessary to define the disease. is exceedingly difficult, either from a clinical or an ætiologic standpoint. Formerly the diagnosis was based upon a clinical picture the essentials of which were a chronically enlarged foot with sinuses from which were discharged small granules of various colours and consistency, accompanied by a peculiar oily degeneration of the tissue. However, when bacteriologic studies began to show the multiplicity of the organisms concerned in the production of Madura foot it became necessary either to consider it a "clinical" entity of "multiple" ætiology or to attempt an "ætiologic" classification. This was made still more imperative by the discovery that the organisms causing this symptom complex were found also producing lesions in other parts of the body. A number of authors have continued to use a clinical classification, while others have attempted to give one based upon ætiologic findings. The result is great confusion in the nomenclature of the disease. Authorities differ as to where the group of organisms belongs in the vegetable kingdom, some placing it among the bacteria and others higher up among the fungi. Practically all the latest writers upon the subject agree as to the great similarity between the various species of these organisms and the majority have placed them as species of a single genus, or as parts of two or even three closely allied genera. In order to establish a uniform and clear conception, and after carefully studying all phases of the question we have decided tentatively to accept 'Streptothrix' Cohn 1875, as the generic name of the group of organisms under discussion.

THE DISEASE DEFINED.

Mycetoma may be defined and classified in one of three ways, if "Streptothrix" is accepted as the most available generic name.

(I) It may be considered as a clinical disease of multiple ætiology (which may or may not be limited to "Streptothrix" infections); (2) the term may appropriately be made synonymous with streptothricosis. actinomycosis, nocardiosis, etc.; (3) it may be made a clinical type (foot infection) by a "Streptothrix (Actinomyces or Nocardia")." Each of these classifications has something in its favour and also may be criticised. The first would make diagnosis easy, for all forms of foot enlargement giving certain clinical manifestations regardless of the ætiology, known or unknown, might be included, but it is open to the objection of not being definite and does not conform to our present methods of ætiologic classification. The second method has much in its favour and is practically adopted by Manson. The objections to it are that it adds a new significance to a term which does not clearly express

<sup>(</sup>a) Abstract of Paper read at the Bombay Medical Congress, Feb. 25th, 1909, in reference to "Schemes for Sanitation in India."

the conditions and also adds a further synonym to a group of infections already rendered confusing by the number of its synonyms. The difficulty can more

the number of its synonyms. The uniform more satisfactorily be met by the third method.

We have therefore decided to follow the third classification making mycetoma a "clinical" type or variety of streptothricosis—"Streptothricosis pedis" —and to define it as follows: A disease consisting of a "Streptothrix" infection of the foot ("Streptothricosis pedis, Actinomycosis pedis"), characterised by a chronic course, swelling and deformity of the part, a peculiar, oily degeneration of the tissues with cavity and sinus formations and the discharge through the fistulous openings of mycotic aggregations containing the micro-organisms. Mycetoma, with this definition, becomes so intimate a part of streptothri-cosis that a balanced conception of it can only be obtained by a study of the whole subject of streptothricosis and a classification of the organisms concerned. For this reason, the scope of this paper has been enlarged to include a discussion in two parts of the whole subject of "Streptothrix or Nocardia" infections.

#### SPECIES DETERMINATION.

Following the generic name of the entire group of organisms under consideration, the next logical step of the problem is a discussion of the species properly belonging to the genus. The classification of species is a more difficult problem than the generic determination, largely because of the imperfect description of many of the so-called species or varieties. In fact, but few have been described with sufficient

clearness to make determination possible.

If we carefully study the literature of species determination, it will be found in greater part to be only of historic interest and value. The work is generally too incomplete to be final for species determinations, and in cases even the generic position of the described parasites is doubtful. For this reason we have considered only the technical descriptions of the organisms which have been cultivated and described with sufficient accuracy and completeness to make them available for comparative purposes. Much of the work of the older writers was well done when due consideration is given to the technique developed at the time of publication, and this work should always be kept before us in giving historical summaries. Many of the articles in the literature are incomplete, and a careful study of such descriptions as are given convinces us that not more than ten different species are represented in the group. Several of the varieties may show slight morphologic and biologic differences, but these are not sufficient to warrant their being classed as separate species.

DISCUSSIONS AND CONCLUSIONS.

The subject of streptothricosis or nocardiosis becomes somewhat simplified if the results of our own work are combined with those taken from the litera-ture, but we realise fully that after considering all possible evidence, points must still remain open for discussion, and complete harmony regarding this subject can only be obtained by common adoption of a somewhat arbitrary classification.

It is difficult to determine upon the correct name of the disease, because of the botanical confusion regarding the position and designation of the group of organisms concerned, and of the lack of clearness of definition specifying definite limitations for the organisms to be included as the ætiology factor.

Whatever the nomenclature, it is a fact that we have here a group of closely allied vegetable parasites of man and animals, which have the following principal characteristics: Branching, filamentous organisms which develop into colonies made up of the organisms and "transformation products." The terminal hyphæ may or may not be radially placed on the surface of the colony and they may or may not develop "clubs." The group in general take Gram's stain and several members show acid-fast properties in a varying degree. The organisms grow on artificial media, differing in their requirements for oxygen and in pigment productions. To a less degree they show other variations in appearance on artificial media. The majority of the organisms produce lesions in monkeys, which histologically resemble those found in the human infections and in those of other animal diseases caused by members of this genus.

There is, in human pathology, a very important group of branching, filamentous micro-organisms which logically belong to a single genus. The generic name is variously given as "Streptothrix, Actinomyces or Nocardia"; the last of these names is probably scientifically the most correct, but because of the present botanical confusion and uncertainty of the present botanical confusion and uncertainty the first is here employed because of its more general acceptance.

#### IMPORTANT SPECIES.

The following species, to judge from our work and from a study of the literature, are the most important and may be recognised as established. (There are probably a number of others, but the description of many of them are too imperfect to allow of their recognition):—"S. actinomyces," Bostroem, 1850; "S. actinomyces," Wolff and Israel, 1891, and Wright, 1905; "S. nocardii"; "S. eppingeri"; "S. madura"; "S. capræ" Silberschmidt.

The disease caused by infection with these parasites is properly named streptothricosis, with actinomycosis and nocardiosis as synonyms. Other names, such as lumpy-jaw, madura foot, mycetoma, etc., should be considered more as describing anatomic location rather than as designations, relating to any special or specific cause of infection. Mycetoma might well be taken as the correct name for the group of infections if a strict interpretation of rules of nomenclature is followed, but usage renders it perhaps more desirable to retain the name as representing "Streptothricosis pedis." If mycetoma is to be considered in any more comprehensive light than this, it should become another synonym for streptothricosis. It should not be considered a disease caused by organisms other than "streptothrica."

#### CHARACTERISTICS.

Streptothricosis is an infectious disease of man and animals caused by one or more species of "Streptothrix." It is characterised anatomically by a peculiar low grade of inflammation, usually confined to one part of the body, but in rare instances assuming the proportions of a general infection. The inflammatory process usually is accompanied by suppuration of a certain kind; the discharges contain granules made up principally of colonies of "Streptothrix." The general picture of chronic inflammatory disturbance is seen clinically, and enlargement, suppuration and the presence of the causative organism in the lesions is observed locally.

The diagnosis of "Streptothrix" infections is made clinically by the character of the exposed lesions and discharges and by laboratory methods. Obviously, the common and frequent involvement of internal organs is rarely recognised except by microscopic examinations at operations or at autopsy. The thoracic types may be determined by microscopic and bacteriologic studies of the sputum or aspirated fluid from the pleural cavities. It is generally stated by competent observers that these types are frequently overlooked, even in sputum examinations and it is not improbable because of the acid-fast properties of some of the organisms that they may occasionally be mistaken for the tubercle bacilli.
The resemblance may, at times be quite close. In some of our experimental lesions the similarity has been striking. The microscopic examination of material from exposed lesions often requires some patience and care to enable the observer to find the been striking. organisms; unless a granule is encountered, when, of course, the determination is easy. Inasmuch as some other closely related organisms such as "Oidia, Leptothrix and Cladothrix" may cause somewhat similar lesions, "Streptothrica" should not be diagnosed positively without careful microscopic study of the organisms present in the lesions.

PROPHYLAXIS AND TREATMENT.

Prophylaxis.—From what we know of the distribution of the organisms of this disease and the mode of transmission and the prevalence of certain anatomical types, prophylaxis should consist in guarding against wound infection and generally by care in food and drink. In the Tropics most of the types consist in local foot or other skin wound infections, which should be guarded against by wearing shoes and by promptly treating skin wounds and abrasions accord-

ing to antiseptic methods.

Prognosis.—The prognosis depends to a considerable extent upon the location and extent of the lesions. The general infections and those of the internal organs almost always end fatally. The external types are much more amenable to treatment and the mortality is small. According to the statistics of Duvan, and Poncet and Berard who analysed 257 cases, the mortality was as follows: Skin 2.3 per cent.; face and neck, 10; jaw and temporal region, 30; abdominal cavity and intestine, 65; thoracic, 85; liver, 100; and brain and spinal cord, 100. The mortality in mycetoma, under proper treatment, is very small. The course of the disease is usually chronic, but it may be general and acute, and general infection may take place during the course of a chronic localised type of the infection.

Complications.—While streptothricosis may be found together with a number of other diseases, or may develop its symptoms as sequels of other diseases, the principal direct complications are those due to mixed infections of bacteria. Several of the pathogenic bacteria have been found associated with "Streptothrica" in lesions and the course and outcome of the disease is influenced accordingly. Tuberculosis, because of its close clinical relation to streptothricosis and the frequent lung involvement of both organisms, has led to confusion in some of the reported cases.

Treatment.—The varieties of treatment most useful in this disease are general, as well as local surgical intervention, if cause is indicated and a combination of all these methods may be necessary. Potassium iodide administered in large doses over a long period of time is generally admitted to have a favourable influence on the course of the disease and complete cures have been reported from this method of treatment. Local measures consist in antiseptic dressings and the use of the Rontgen rays. Surgical measures consist in drainage, removal, or amputation according to the location and extent of the lesions. A combination of all three forms of treatment would suggest itself as offering the most favourable opportunity for recovery.

#### CLINICAL RECORDS.

NOTES OF

TWO CASES OF "PURPURA HÆMORRHAGICA"
TREATED WITH POLYVALENT ANTI-STREPTOCOCCIC SERUM. (a)

By J. A. COUTTS, M.B.CANTAB., F.R.C.P.

As an addition to the cases of recently reported purpura, brief notes of the two following ones may be of interest. The classification of cases of purpura is still unsettled, and more or less in a state of chaos. The ætiology, too, in a majority of cases is equally uncertain. Especially is this last the case in dealing with so-called "purpura hæmorrhagica," taking this title in its widest definition, as including all cases where hæmorrhage into the skin is complicated with bleeding into deeper parts. The more usual sites for these internal hæmorrhages are the gastro-intestinal track or some part of the urinary system, but in cases with an identical affection of the skin bleeding may occur into the pericardium, the lungs, the brain and its meninges, the joints, and numerous other situa-

(a) "West London Medico Chirurgical Journal," September, 1908.

tions. The prognosis in "purpura hæmorrhagica" is as uncertain as the ætiology is obscure, but in cases of any severity the mortality is far from inconsiderable. A recent theory that some of these cases of "purpura hæmorrhagica" are of microbic origin is receiving increased support, and the theory is strengthened by success in treatment based upon it. (a) If further experience should confirm the success of this treatment, then its adoption marks a distinct gain in therapeutics.

A. O., æt. 3½, was admitted into the East London Children's Hospital on February 24th, under my care. A week before (Monday, February 17th) the mother noticed "spots and bruises" on the back, and the following day these "had spread all over him." Three days after the first appearance of the spots bleeding occurred from the mouth, gums, and nose, and one day later the water contained blood. There had been no vomiting, and there was no complaint of pain in joints or abdomen. The child had never been ill before, and the family history contained nothing of

interest.

On admission the patient was a well-nourished child, but blanched from hæmorrhage and apathetic. His face, body, and limbs were thickly covered with purpuric spots of medium size, and there were some larger bruises in one or two regions. The more recent spots were bright red, and the older ones were undergoing the usual changes in colour. The mucous membranes, lips, gums, and eyelids were extremely pale, and there was some slight hæmorrhage on the surface of the tongue. There was a well-marked hæmic murmur at the apex of the heart. The motions were normal, but the urine apparently consisted of little but pure blood. A blood examination showed Hb. 35 per cent., red cells 2,500,000, white cells 6,000. The temperature which was 98.4° F. on admission, fell to normal the same night, and did not rise above normal again. The case was unmistakably a severe one and the prognosis grave. The child was put on 5-grain doses of calcium lactate every four hours, and a rectal injection of 10 c.c. of polyvalent anti-streptococcic serum, three of these injections being given altogether at intervals of two days.

Two days later, February 26th, the child was much better; one or two fresh purpuric spots have appeared on the abdomen, but the rest of the eruption is failing. The urine is no longer bright red, and contains much

less blood.

A week later, March 4th, the urine contained no albumin, and showed no trace of blood by the guaiacum test.

March 8th: The child is now quite well and the

purpuric eruption entirely disappeared.

M. S., æt. 13, was admitted into hospital on March 2nd, under my care. Five days previously, February 27th, he complained of pain in his right leg from the knee downwards. Two days later, February 29th, a red patch developed over the right elbow, and there was pain and swelling of the joint. The next night, March 1st, the left elbow became similarly painful and swollen. In addition to that in the swollen joints there was pain over the body generally, not especially severe in abdomen. There was no history of hæmophilia or bleeding from gums or elsewhere. On the day of admission the boy was seen, in the surgical out-patient department, by one of my colleagues. There no diagnosis was arrived at, but the patient was sent in with the suggestion that the case was possibly one of some form of epiphysitis.

On admission the patient was a fairly nourished lad. Both elbows were swollen and painful both to pressure and passive motion. On careful examination in a good light there seemed to be some infiltration into the skin around the elbows, and on the right some very slight discoloration like that of a fading bruise. It was considered that the joint effusions were probably hæmorrhagic, and an exploratory needle inserted into one drew off only a slight quantity of blood. There were no other cutaneous

<sup>(</sup>a) Soltau Fenwick and Porter Parkinson, "Med. Chir. Trans.." London, vol. lxxxix., 1906.

hæmorrhages, and the urine contained neither albumin nor blood. The temperature was normal and the leucocyte count 9,000. As one of my colleagues considered the proof of the value of the neither serum treatment in the former case was discounted by the fact of the simultaneous administration of the doses of the last drug, every four hours, and the serum temporarily withheld. A week later, March 9th, the patient was worse. The swelling of the elbows had disappeared, and there was some discoloration, like that of a fading bruise in the neighbourhood of each joint. A cutaneous swelling had developed over the left forearm, and both hands were puffy and swollen. The day before swellings, which were taken to be hæmatomata, had appeared in the scalp over each parietal bone. These quickly in the scalp over each parietal bone. These quickly invaded the whole side of the head, thrusting the ear before them on both sides. There were a few small purpuric spots on the side of the nose, and some larger ones dotted sparsely over the lower extremities. For the last two days there had been abdominal pain and the motions contained a considerable amount of dark blood. The calcium lactate was then dropped, and the boy given a rectal injection of

20 c.c. of anti-streptococcic serum.

The further progress of the case can be briefly summed up. The hæmatomata speedily resolved, and the swellings over the left forearm and hands disappeared, leaving faint, bruise-like stainings. About week after the injection the boy had a return of abdominal pain, and a trace of blood reappeared in the stools. He was then given a second rectal injection of 20 c.c. of the serum. After this he had no further trouble, and his progress to recovery was uninterrupted. About ten days, however, after the first rectal injection a profuse coppery-coloured eruption developed, mainly around the ankles and the elbow-joints. My colleague, Dr. Graham Little, who kindly saw the case for me, was inclined to regard this as a manifestation of the original disease, but I attributed it to the effects of the serum, the rash from the last being modified perhaps by the boy's tendency to purpura. It gradually faded without taking on the hæmorrhagic character of the previous purpura

These two cases in themselves prove little, but they are at least confirmatory of the excellent result of the serum treatment of purpura hæmorrhagica in the hands of others. I used the anti-streptococcic serum mainly because, as far as I know, it is the only one that has been tried with success in such cases. It is quite possible, however, that other forms of sera would prove equally efficacious. Such interesting results, indeed, are now being obtained in numerous conditions by the use of normal serum that I would feel inclined to give it a trial in future cases of purpura hæmorrhagica.

Many of the fortunately rare cases of acute hæmatemesis in infants are now regarded as belonging to the category of purpura hæmorrhagica. Whether anyone has used the polyvalent antistreptococcic serum in such cases I am not aware, but the remedy would seem well worthy of a trial in a complaint where recovery so seldom occurs.

#### **OUT-PATIENT'S ROOM**

CREAT NORTHERN HOSPITAL.

F'at Foo!

BY ARTHUR EDMUNDS, M.S., F.R.C.S.

AMONGST the out-patients was a girl, æt. 16, who came up with her foot in plaster of Paris. She had presented herself at the out-patient department several weeks previously complaining of severe pains in the left foot. She was a tall, overgrown weakly girl, and it was obvious that before it would be worth while attempting any serious treatment of the flat foot her general health would require careful attention. Accordingly arrangements were made for her admission to a convalescent home for a few weeks, and she returned from the institution considerably stronger, and in better health in every way.

Flat foot, Mr. Edmunds said, is primarily in this type of case due to a muscular weakness, and it must be remembered that however efficient the treatment for restoration of the arch, the support of this structure ultimately depends on muscular tone, and for this reason the patient's general health is of prime importance. The condition present in this girl was more however than a mere muscular defect as it was impossible to restore the arch by posture or by simple manipulations. The head of the astragalus formed a conspicuous projection on the inner side of the foot, but there was no evidence of any deformity of this bone. The patient had been admitted to hospital, and under chloroform the contracted ligaments on the outer side of the foot had been torn across, and the foot forced into a natural position, the prominence caused by the astragalus completely disappearing. The foot was then put up in a firm plaster of Paris casing which was left on for three weeks. At the end of this time the patient once more presented herself at the out-patient department, and the plaster was carefully removed in such a way as to allow the posterior and lateral portions to used as a splint until a proper apparatus could be constructed. This Mr. Edmunds pointed out is best made on the lines laid down by Whitman, that is to say a cast is taken of the foot as it lies upon its outer side with the arch restored as much as possible. method adopted in this case is, he thought, perhaps the simplest: the foot is well greased or oiled and arranged upon a chair similar to the one on which the patient is seated, lying upon its cuter side, the knee being flexed nearly to a right angle. A thick plaster cream is then mixed, and a sheet of lint about a foot square thoroughly impregnated with it; the foot is laid upon the sheet with the outer border parallel to and about three inches from one of its sides. The lint is then folded up over the sole of the foot and brought up on the inner side to a point just at the level of the internal malleolus; al! projecting corners are folded backwards towards the sole, and the plaster allowed to set. When this has occurred the foot is allowed to set. When this has occurred the root is removed from the plaster casing, a matter of but little difficulty, especially if it be done before the plaster is quite hard. A few cracks may form, but it would be easy to make these close without distorting the mould. The mould is now lubricated, and some fresh plaster cream prepared come explanation. and some fresh plaster cream prepared; some ordinary tow is impregnated with this cream and laid in the mould so as to build up a thick hollow lining to it. When this fibrous plaster has set the mould can easily be removed by forcing open the two sides and a cast of the foot obtained when which the addiagram and of the foot obtained, upon which the ordinary markings by Whitman's brace can be made for the instrument maker. This method, he considered, is simpler and more accurate at any rate in any but the most skilled hands than the method of making a plaster cast in two halves, and the whole process can be finished with but very little mess in about twenty minutes. When this cast has been satisfactorily made the plaster casing is reapplied, and the patient sent home until the steel brace can be prepared.

#### OPERATING THEATRES.

ROYAL FREE HOSPITAL

APPENDICITIS WITH ABSCESS .- MR. WILLMOTT EVANS operated on a young woman, ret. 23, who had been complaining for about three weeks of an indefinite dull pain in the right iliac region. She had felt out of sorts, but had been able to do her ordinary work. On the day before admission the pain had become more acute, and she had had some fever. A doctor had then seen her, and had recommended her removal to the hespital. When admitted the abdominal wall in the right iliac fossa was found to be rather har though it moved slightly on respiration. Nothing definite could be felt on palpation, though she complained of a little tenderness. The bowels were acting regularly; her temperature was a little over 100°, and her general condition seemed very good.

It was decided to watch the patient; she was ordered milk diet. The next morning she remained in the same condition, and the day following also, but on the evening of the third day the temperature began to rise, and when the patient was seen by Mr. Evans at 10 o'clock the temperature was 102°, and a definite localised swelling could be felt in the right iliac fessa. He decided to operate at once. The patient was taken to the theatre and anæsthetised. An incision was made in the right iliac fossa directed to the right iliac fossa directed and inverted and inverted its length was about three downwards and inwards, its length was about three inches, and its upper extremity situated about three inches above, and internal to the anterior superior iliac spine. The incision was deepened until the subperitoneal tissue was reached; as far as possible the muscular fibres were separated rather than divided. Slight ædema of the subperitoneal tissue was noticed, and the peritoneum had a yellowish tinge. An incision was made through the peritoneum, and some four ounces of pus were evacuated. The cæcum presented in the wound, and by gentle rotation it was possible with very little disturbance of the parts to reach the base of the appendix. The appendix was ligatured close to its base, and was cut through. About an inch of it was removed as far as the place where it was completely disorganised. The meso-It would not have been appendix was ligatured. possible to discover and remove the remainder of the appendix without much more disturbance of the parts.

A drain was inserted into the abscess cavity which was found by a finger to pass inwards over the brim of the pelvis. The wound was dressed with cyanide gauze after a couple of stitches had been put in in the

upper end of the incision.

Mr. Evans said the time for operating on a case of appendicitis is still unsettled. When appendicectomy was first introduced the practice of many surgeons was to operate for the removal cf the appendix at the earliest possible moment, and this practice was even more prevalent in the United States of America than in this country. A few surgeons still maintain that it is wise to remove the appendix as soon as the diagnosis of appendicitis is made, but in this country at least they form a very small minority. Very soon it was recognised that the best time to operate on an appendix was not during an attack of appendicitis, but after that attack had subsided, and therefore it is the custom now with most surgeons to postpone operation in some cases while they operate early in others. In classifying these cases for therapeutic methods a sharp distinction must be drawn between those in which an abscess has formed and those in which no abscess has formed. To consider the latter class first, Mr. Evans said: If we were to leave these cases untreated we should find that in a large proportion of cases of appendicitis in which the symptoms are not very acute recovery will follow without any surgical treatment. In some of these no second attack of appendicitis will ever occur, while in others a second attack, third or even more will follow at irregular intervals. What then should be done? He thought it might be laid down as a rule that in cases where the general condition of the patient, the small degree of fever, the quietness of the pulse point small degree of lever, the quietness of the pulse point to a mild attack, it is well worth while to postpone any operative interference until the attack has subsided; then if indications for operation are present appendicectomy can be done. What are these indications? If after the first attack some palpable swelling is left behind or marked tenderness, then he considered it advisable that operation should performed without waiting for a second attack. Still more if the appendicitis just past is not the first, but the second, third, or later attack, the indication for operation is still more imperative. If on the other hand the attack is the first from which the patient has suffered, and physical examination after its subsidence gives no evidence of any abnormal condition, no thickening, no swelling, then he thinks the surgeon is justified in suggesting that the operation should be postponed for a time to see what may happen; and it will be found that in a large proportion of these cases, probably over 60 per cent., no further attack of appendicitis will ever occur. The operation of

appendicectomy in the interval between two attacks (the interval operation as it is called) is accompanied by an exceedingly low mortality, in fact in competent hands it has no mortality at all. There are, however, some cases in which though no abscess has formed, the attack is of an exceedingly great virulence: the microbic involvement of the appendix has resulted in widespread death of the appendical wall, and the sloughing wall will give way, and the contents will pour out into the general peritoneal cavity before any protective adhesions have had time to form. The only hope of saving these cases is by immediate removal of the appendix. How then can these full protecting cases he recognised. these fulminating cases be recognised? Some say that it is impossible to recognise them, but Mr. Evans thought this view was too pessimistic; many points have to be considered, and too much reliance must not be placed on any single point. First as to the temperature. Severe cases are usually characterised by a high temperature, though it must be remembered that sometimes the temperature is normal or even subnormal. The pain is also usually more acute, and the rigid motionless abdomen points in the same direction. On the whole the most trustworthy criterion is to be found in the pulse, the rapidity of which is usually out of all proportion to the temperature. He would also lay great stress on the general aspect of the patient: it was impossible to describe in words, he said, what that aspect is, he could only say that the patient looks more ill than his symptoms and signs would suggest he was.

Secondly, he spoke of those cases in which an abscess has formed: in these it is well to evacuate the pus as soon as proof of its presence has been obtained, but as a rule it is not advisable to insist on removing the appendix at the same operation unless the lie of the parts renders it possible without risking the hreaking down of protective addesions.

ing the breaking down of protective adhesions.

Lastly, he pointed out there are certain cases in which an abscess has formed, and has burst into the general peritoneal cavity before the surgeon has seen the case. He would only say at present that the best treatment was to drain the abdominal cavity as thoroughly as possible, the result depending, in his opinion, rather on the nature of the microbial infection than on the special method employed for cleansing the peritoneum.

The abscess cavity in the present case slowly filled up, and eventually healed, though there was some weakness of the abdominal wall at the site of the scar.

#### TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

MEETING HELD FRIDAY, MARCH 26TH, 1909.

The President, Dr. W. G. SMITH, in the Chair.

GAS IN THE STOMACH: ITS CAUSATION AND TREATMENT. DR. CAHILL defined the terms "fermentation" and "putrefaction"—the former being mainly applicable to the decomposition of "carbohydrates," the latter to the decomposition of "proteids" and "fats." The end-products of each process was discussed. The causal factors in the production of gastric gas were considered under the following heads:—(1) Air swallowing. (2) Chemic gastric respiration. (3) Mechanic gastric respiration. (4) Inorganic production of CO<sub>2</sub>. (5) Organic production of CO<sub>2</sub> and associated gases. (6) Spasm of cardia or pressure from without. The treatment of the various causes—including "lavage" diet, rectal feeding, drugs—was referred to, and a plea was made for the more careful investigation of the causes of "flatulency."

The PRESIDENT took exception to the distinction drawn between fermentation and putrefaction. He looked on putrefaction as a mere accident of decomposition; it was simply fermentation plus smell. He thought the terms were not susceptible of accurate

definition in the sense in which Dr. Cahill used them. He was not hopeful of the possibilities of intestinal antiseptic treatment, as none of the things used had

come up to expectation.

Dr. Cox said it was a rare thing for an amount of air capable of causing trouble to get into the stomach by swallowing. He thought the troubles must be looked for within. They had seen cases where mental trouble or sudden shock had led to gas being formed by a process which was probably neither fermentation nor putrefaction, and in which a great amount of misery and depression was relieved by the expulsion of gas. In such cases he thought the subjective sensations were as much to be accounted for by the depression associated with mental causes as by poisoning of the blood by the by-products of digestion, or the un-

eliminated products of liver digestion.
Sir John W. Moore said that people with bad teeth, who could not masticate their food, swallowed with it very considerable quantities of air. They were familiar also with the connection between cardiac and vascular lesions and gas in the stomach. It was exceedingly hard to disinfect either the stomach or intestines, but symptoms could often be relieved by attention to the toilet of the mouth.

attention to the toilet of the mouth.

Dr. Cahill, in reply, said the distinction drawn between "fermentation" and "putrefaction" is only for clinical use, seeing that the processes exhibit no absolute line of demarcation. Stress laid on air swallowing by Sir John W. Moore is in agreement with the observations of the writer. An illustrative case of inflammable gas (CH<sub>4</sub>) was quoted, a parallel to that noted by the President from the work of Sir Henry Marsh. Henry Marsh.

NOTES ON A CASE OF PORT WINE COLOURED URINE (H.EMATOPORPHYRINURIA).

CHLEMATOPORPHYRINURIA).

Dr. PARSONS said Miss A. B. came under his care early in June suffering from diffuse abdominal pain, vomiting, and constipation. The urine, on standing, became of a deep port wine colour (specimen exhibited). It contained neither albumin nor blood. Neither trime after ten days patient improved and Neither trional nor sulphonal had been administered at this time. After ten days patient improved, and went away for a change. The symptoms, however, recurred, and she was admitted to hospital towards the end of June. Abdominal pain was present. Sleeplessness was pronounced, and she was given on four consecutive nights 15 gr. of trional. The urine was of a similar colour to that passed early in her illness. Towards the end of the first week after admittance she complained of severe pain in her feet, and on July 7th complained of severe pain in her feet, and on July 7th her arms were almost powerless, and she was so ill and feeble that she could barely move in bed. On July teeble that she could barely move in bed. On July noth the rectal sphincter was relaxed and she commenced to pass under her. A few days later swallowing became difficult, and death took place in a little over two weeks after her admission to hospital, and in less than seven weeks from the onset of her symptoms. Specimens of the urine passed shortly after her admission to hospital, and a day or two before her death, were exhibited. They were of a rich port wine colour, and, though nearly three years old, were acid in reaction and showed no evidence of decomposition. Though hæmatoporphyrin was probably present, the red colour was not due to this substance, and it was considered that the term hæmatoporphyrinuria, applied to urine of this class, was misleading.

The paper was discussed by the President and Dr. Eustace.

#### CORRESPONDENCE.

#### FROM OUR SPECIAL CORRESPONDENTS ABROAD.

GERMANY.

Berlin, April 11th, 1909.
At the Medical Society, Hr. Ernst Rosenberg spoke

DIAGNOSIS AND TREATMENT OF DEEP-SEATED DISEASES OF THE COLON.

In describing the means of diagnosis, he first mentioned digital examination, examination of the fæces,

and recto-romanoscopy. It did not matter with what instrument the latter was carried out. Any of those described answered the purpose very well. It was rather a question of which the user was the most accustomed to. It was not necessary to inflate with air. The parts should be thoroughly cleaned, after which the knee-elbow position could be made use of. He gave a note of warning against the use of the sound. He described acute and chronic inflammations of the large intestine, and the usual treatment. He dwelt on the treatment of the chronic form of inflammation of the colon, and recommended flushing of the parts with astringents, after first washing out with soda solution. When the end was not attained by this means, he made local applications in the form of powder (magn. ust. tannin, and zinc. sozoiodolicum), by means of the recto-romanoscope. The aim was attained by this method only when the extreme upper The aim was Amongst the diseased surface could be reached. Amongst the diseases of the large intestine a special place was taken by strictures, for the treatment of which he made use of dilators which he had had constructed after the manner of Kollmann's urethral dilator.

At the Verein für Innere Medizin, Paul Mayer contributed a note on

#### BOUMA'S DIABETES MILK.

This milk contained only the smallest quantity of milk sugar (about o.1 per cent.); it was rich in fat, well tasted, and it could be sterilised. He had procured it in a sterilised condition from Vienna, and had used it with success in a number of cases of diabetes, the success being specially pronounced in the cases marked by emaciation. The milk could be obtained in Berlin in a fresh state, price about 6d. the half-litre.

Hr. Langstein showed an eight months' child that for the last four weeks had suffered from intestinal catarrh, with great thirst. On examining the urine it was found to contain 3.5 per cent. of sugar. This proportion was greater than had ever been recorded in the case of so young a child, with the exception of one reported by Rossbach, coming on after injury to the head. He had prepared a sugar-free milk, and after the use of this the sugar entirely disappeared from the urine; a marked acidosis, however, still remained. It was ascertained that the mother had given the infant large quantities of sugar every day for the last six months (200 grm. a day).

Hr. F. Blumenthal was in entire agreement with Mayer's favourable opinion of Bouma's milk. Its decomposition differed from that of other milk. As it contained no sugar it did not turn sour, but decomposed; but the products of decomposition did not make their presence known by emission of sulphuretted hydrogen until after the fourth day.

#### A CASE OF FÆCAL TUMOUR.

Hr. Lazarus related the case of a young man, æt. 35, who had suffered for five years from tuberculosis and diarrhæa, with abdominal pains, so that the bowel affection was looked upon by the medical man in attendance as tuberculous. There was persistent diarrhæa, which could only be kept in check by large doses of opium. When the speaker first saw the patient he was in a very much reduced condition; on examination a large, nobbly, easily movable tumour examination a large, nobbly, easily movable tumour was felt in the region of the colon, the nature of which he could not at the time determine. It might be the rolled up omentum, but the ease with which it could be pushed downwards was against this view. It might be a packet of enlarged glands, but against this was the fact that the tumour changed its position every day, and was observed to be smaller after defæcation. The patient got no more opium, his stools became formed, and he ate with a good appetite. But he died. The preparation shown was the colon filled along its whole extent with a stony, hard, black fæcal mass; no way out could be found for it.

Hr. Rothmann, senr., had seen two cases of fæcal tumour, there was high fever in one of the cases. After infusions from a height the tumour diminished in size and at last disappeared; finally a blackish, stony hard piece came away. The second case was stony hard piece came away.

similar to the first, was treated and ended in a similar manner

Hr. Kraus remarked that in patients treated with tannin such tumours sometimes formed, but Hr. Lazarus said he had discovered no mention of tannin in the prescriptions which he had looked through.

# AUSTRIA. Vienna, April 11th, 1909.

BARLOW'S DISEASE.

KNOPTELMACHER presented a case to the Gesellschaft der Aerzte, aged 9 months, with the typical symptoms of Barlow's disease, viz., pale and anæmic, restless, and great swelling over the left tibia, particularly the and great swelling over the left tibia, particularly the lower third of the bone, where the tenderness and pain were severe. The left ulna was swollen, but the changes were greatest in the middle portion of the bone. There was hæmorrhage into the skin in both upper and lower eyelids, as well as the mucous membrane of the lips and cheeks, while the gums were quite normal. The most striking symptom was the exophthalmus, the left being greater than the right, which led to the presumption of retro-bulbar subperiosteal hæmorrhage in the orbit. been fed with mother's milk at first, but latterly with cow's milk mixed and reduced with water.

POLIO-MYELITIS ACUTA ANTERIOR.

Semeleder showed a female, æt. 14, who was attacked with paralysis in her second year of life in both lower extremities, the right being complete, while the left retained the power of extension and adduction in a small degree. After the lapse of twelve years a faint contraction can be observed, but the contraction of

nothing but orthopædic aid could be offered, but every home and foreign instrument failed to give any relief. Having the shoulders well developed. leder has devised an apparatus by which the force of these muscles can be utilised for hips and legs. With this apparatus the patient can rise and walk about

with comparative ease.

with comparative ease.

TETANY PARA-THYREOPRIVA.

Eiselsberg exhibited a case of tetany, æt. 33, on whom he had operated for goitre in 1905, which had caused a good deal of constriction in the air passage by the stenosis in the trachea. A few days after the operation tonic cramps in the hands and feet commenced, while Chvostek and Trousseau symptoms were well marked. The use of thyroid tablets only gave temporary relief, which were persevered in till the following year, when it was deemed advisable to transplant a few epithelial bodies into the sheath of the rectus muscle, but in spite of this, though feeding with raw sheep's gland and taking the tablets regularly, the cramps persisted. In June, 1908, she became larly, the cramps persisted. In June, 1908, she became pregnant, when the fits relaxed, but a month ago they commenced with more severity than ever in the upper and lower limbs, with great difficulty of breathing at night. The right vocal cord is paretic, and the voice is hoarse. The left ulnar is active under the galvanic current, but not unduly excited. In conclusion, he criticised the removal of the epithelial bodies, and thought they were too important to be neglected. He had no doubt the extirpation of these bodies with the gland was the cause of the tetany, which may be alleviated by transplantation, etc., but seemed to fail

UNILATERAL TABES.

Flesch recorded a peculiar case of tabes affecting one side of the cord, though the symptoms were often bilateral. The tendon reflex of the Achilles was not affected on the right side, though quite lost on the

Wirth asked if lumbar puncture and Wassermann's test, when applied, or the globulin reaction of Nonneapelt, would be of use in these cases; but Flesch could see no useful end these would serve.

Algyogyi said he had observed lightning pains in the lower intercostal spaces of one side in tabes, cases which may be of the same nature as Flesch's results.

PRECIPITATION IN TUBERCULAR SERUM.

Stork recounted the result of 800 cases on whom he had experimented with a 1 per cent. solution of

carbolic acid in a physiological solution of common salt. When this is added to the sera of phthisical patients, and the mixture placed in the incubator for 12 hours, a precipitate is formed, while a "bacillen-lipoid" is found floating on the surface, which seems to come from the bacilli in the fermentation. When emulsified, a ½-gram of lipoid material may be obtained from a ½ of a litre of the saturated solution. He found this in 75 per cent. of his cases, all of whom were suffering from pulmonary tuberculosis. Unhappily the reaction is not confined to this class of cases, Unhapas he found it present in tumours and diabetes when well advanced. It was also met with in the first stage well advanced. It was also met with in the first stage of infectious diseases, or after a rich milk diet. It is worthy of note that the morning serum is devoid of this reaction. Other bodies, like lecithin, glycocholate of soda, and even vaseline, require to be guarded against in this reaction.

#### HUNGARY. Budapest, April 11th, 1909.

SHORTSIGHTEDNESS 14 CHILDREN.

In concluding his very instructive article on the examination of 200 school text-books from a sanitary point of view, Dr. Fejér draws particular attention to the fact, as substantiated by many prominent investi-gators, that shortsightedness in children either originates or develops in school. The chief causative agency, therefore, is to be found in too prolonged reading, writing and drawing, whereby accommoda-tion as well as convergence are greatly fatigued. Undue strain of the muscles of accommodation causes an active hyperæmia, the return flow of the venous circulation is greatly hindered, there is an increase of the intraocular pressure, and the sclerotic is gradually stretched. Too strong convergence works even greater harm for the eye in various ways. It must also be observed that in some of the children shortsightedness is hereditary and they become affected so much sooner than their healthy comrades. In addition to the above cause producing shortsightedness, mention must be made of poor, or insufficient lights with which many school buildings are supplied; the same may be said of unhygienic school furniture. As regards the influence of books on eyesight, the author insists that paper should not be polished, for under artificial light a polish on a paper prevents the eye from seeing well, and necessitates moving the book to and fro, as well as frequent changes in the position of the head. Again, the paper should be thick enough to prevent the printing of the next page from intruding itself upon the reader's eye. Although a few authors recommend yellow paper, the majority speak in favour of white, for the contrast between the print and the paper is so much more striking the whiter the paper. PREVENTION OF IODISM.

Dr. Leser believes (Orvosok Lapja, 1909, No. 13) that iodised alkalies suddenly flooding the organism, and pouring out through the mucous membranes, cause catarrhal conditions on these, and thus lead to iodine intoxication. He suggests, as a prophylactic measure, that the iodine salts be administered in a mucilaginous vehicle in order to render absorption slower and gradual. In some cases it may be advisable to give the iodine per rectum, where absorption is also slower. Another prophylactic measure is to use the iodine in the form of iodised fats, or the injection of iodipin. In cases of pronounced idiosyncrasy, the latter may be used at first in small injections in order to accustom the organism gradually, and then the internal administration may be gradually substituted.

ANTI-STREPTOCOCCUS SERUM IN ARTICULAR

RHEUMATISM.

The employment of sera in this disease has been made the subject of careful study by Dr. Weiss, of Pistyan (Hungary), who claims that the lymphatic ring in the pharynx affords the point of entrance for the cocci, as also stated by Menzer, of Germany. Weiss produced his serum from streptococci derived from the original, associated with articular rheumatism. As the serum is not passed through animals, however, exact dosage is not possible, he has lately made a new test of this agent in 15 cases, most of which were characterised by an early passage from the acute into the chronic stage, and in which other remedies had met with little or no success. From one to eight injections were given in each case, the dose varying from 5 to 20 cc.m. The quantity was rapidly increased until a distinct reaction was obtained, the next injection being then delayed until the effects of the other had fully subsided. The reaction varied greatly in different patients. In some there was high fever and marked local changes, in others only the latter appeared, and in a few no change at all took place. Local reactions were observed only in the joints, where the injection had been made, the others remained free. In summarising his results, Dr. Weiss states that definite benefits were seen in six cases, a certain degree of improvement in four, and no effect at all in five. The good effects consisted in an abatement of the pain and increased mobility. He does not believe that this serum exerts a specific action similar to that produced by diphtheria serum or tuberculin. He admits, however, that undoubted results have been obtained, especially in the subacute cases. In acute cases very little effect was observed, and in chronic cases none at all. It does not seem advisable to employ the serum until all other methods have failed, and a better standardising is at present a great desideratum.

# FROM OUR SPECIAL CORRESPONDENTS AT HOME,

#### SCOTLAND.

Mr. Sydney Holland's Allegations Craiglockhart Poor-house.—The Parish Council have communicated to the Press a report dealing with Mr. Holland's attack on the management of the poor-A direct denial of the accuracy of some of Mr. Holland's statements is given—operations are not performed by the lady house surgeon; the consulting medical officer attends at least thrice a week, not twice, as stated; there is no ophthalmic ward; records of all cases are preserved. Other parts of Mr. Holland's charge are described as misleading—(1) The duties of the resident are laid down by the Local Government Board, and a great deal of medical work, e.g., ordering diets, is of a routine nature. (2) There are 9 day nurses and 6 night nurses for the 13 wards; so that to say "many" of the wards have no trained nurses is an exaggeration. (3) The conditions under which operations take place may be likened to what exist in a private house; there is no great amount of surgery done, and to compare the theatre with standards of the same training of the same training and to compare the theatre with standards of the same training of the done, and to compare the theatre with standards of a general hospital is unfair. (4) Not more than half-adozen post-mortems are performed annually. Expert surgical help is available for special cases. Three-fourths of the 280 cases require no active medical or surgical treatment, they are chronic senile, nervous and rheumatic cases, needing little except nursing. The Chairman of the Parish Council points out that while he sympathises with the disappointment one accustomed to the relation that while he sympathies with the disappointment one accustomed to the palatial theatres of London hospitals would feel on viewing the simple, though thoroughly hygienic, arrangements in Scottish poorhouses, the Council can only administer the law as it stands, and they are fully aware of its many shortcomings.

MEDICAL INSPECTION OF SCHOOL CHILDREN.—In a memorandum issued by the Scottish Education Department for the guidance of School Boards, the principle is definitely laid down that for each area a single responsible medical inspector is required. Neither he nor his assistants should be allowed to engage in private practice. In rural parishes it may be possible, however, to utilise the services of local practitioners as assistants, and in some districts the employment of nurses may be indispensible. Great difficulties are anticipated in carrying out the work in certain districts of the Highlands where the population is much scattered. The memorandum is especially emphatic in protesting against any arrangement being come to which will allow of one practitioner being called upon to examine another practitioner's patients.

Notification of Births in Glasgow.—During 1908, 86.3 per cent. of the births were notified, the ratio of notifications to births was highest (99.3 per cent.) in Cowcaddens Ward, one of the poorest districts. In the better quarters of the town it was lower. Of the 20,000 odd births notified, 45 per cent. were attended by medical men, 55 per cent. by midwives. The incidence of puerperal fever was considerably higher in the latter group than in the former; 117 cases were notified, of which 32 had been attended by medical men (3.4 per 1,000), and 85 by midwives (7.5 per 1,000).

#### LETTERS TO THE EDITOR.

[We do not hold curselves responsible for the opinions expressed by our Correspondents.]

#### ALCOHOLIC SHAM TONICS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Some weeks ago you allowed me to call attention to the traffic in sham tonics containing alcohol. I pointed out that vast sums were being spent on advertising these pernicious compounds, a measure of the extent of their sales; that a craving for alcohol was being created in great numbers of innocent people; and that secret drinkers among women were being provided with the means to indulge their vice without some of the restraining shame hitherto existing. Since I wrote, a series of authoritative analyses of these "tonics" has been published, and in every instance it has been proved that they contain as much alcohol as is found in ordinary port wine. Thus the wretched dupes who put their trust in these compounds are often taking the equivalent of from three to six glasses of port a day. No doubt the worst of these concoctions contain no wine whatever. It would take a clever palate to distinguish what is the alcoholic constituent of a mixture of so-called 'beef tea" with various "flavouring" ingredients, and it is not likely that the unscrupulous vendors of such mixtures would use good wine when "silent" spirit would answer the same purpose. I ask again, Sir, whether the temperance organisations would not be well employed in forcing this question on the attention of Government? The Times a few weeks ago had a leader on the "Care of the Inebriate," exposing the evils of the traffic, and advocating the prohibition of the sale of alcoholic medicines by law. This exposure has not, however, stopped the appearance of enormous and costly puffs of these preparations in all the leading newspapers.

I am, Sir, yours truly,

MEDICAL TEMPERANCE REFORMER.
London, S.W., April 10th, 1909.

#### THE DECLINING BIRTH RATE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Through a curious coincidence since offering my few simple remarks on this subject it has come to pass (so the Daily Mail informs us) that the birth rate has risen "The first increase in fourteen years." Moreover I read recently an increase has also taken place in France. I refer to this as a fulfilment of one of my predictions, viz., that amongst the homo species the supply would always be equal to the demand. Perhaps not apparent, but nevertheless real. Let us hope that this increase may not prove the old adage that "The last feather breaks the camel's back."

The facts your correspondent, "Student of Sociology," calls attention to are matters of common knowledge, which no careful observer or constant reader of the daily papers would be likely to overlook. If a diminishing birth-rate on the face of a surplus population, alien emigration, unemployment, intense competition, and widespread destitution is farcically called "Racial suicide," I venture to think an increasing birth-rate under these conditions might with equal propriety and with more reason be styled racial homicide.

Your correspondent's remarks about India are surely ill-timed or inopportune. It should, I think, be

evident that this portion of our Empire is above all others the most fragile and insecure. Religious animosities, the spread of education, the admission of natives in the Supreme Councils of State are perilous in the extreme. No living being can forecast security of tenure in these regions. In the Brighton Herald (November 14th, 1908) there appeared a report of a speech by Mr. Kennedy on the "Curse of Empire," in which he stated: "From January 1st, 1889, to September 30th, 1901, two British subjects in India died from starvation every minute of every day and every night." Assuming this statement to be approximately correct, would your correspondent, I ask, advance this as an argument in favour of an increasing birth-rate and Empire building? But for your valuable space I could add a good deal more,

In conclusion will your correspondent bear in mind that our insular position as a nation, plus the navy, no longer, nor can it in the future, afford us the security as heretofore. The issues of the fight in future warfare are no longer confined to terra firma nor the surface of the water. For what with undercurrent explosives and aerial navigation, which may spill its spoil at any moment, and on any spot, with ghastly destruction so much so that war may almost be described in the future as being waged in the seven heavens and the bottomless pit. The only card (as appears to me) left our country to play is in the spread of agriculture. Landowners will probably realise ere long that title deeds no longer afford the security to their estates as of yore, especially when we discover international treaties are openly defied and brought to nought. Hence landowners may be induced to surrender land, the only possible means of rearing an increasing and healthy population to protect our shores, and which we sorely need, and which we cannot afford under existing circumstances to send abroad.

I am, Sir, yours truly,

CLEMENT H. SERS.

Brighton, April 8th, 1909.

NATIONAL SERVICE AND THE MEDICAL PROFESSION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,-Your issue of March 24th contains a letter from "Criticus," in which an endeavour is made to discredit the system of National Service, on the grounds that it would lead to an increase in venereal disease, and the writer goes so far as to say that, "In Germany it is recognised that military service increases the amount of venereal disease." I trust that you will let your readers have an opportunity of knowing the real truth on this point, vouched for by statistics given on the highest authority. On page 15 of the Report of the Army Medical Department for the year 1906, Table No. 7 shows that in the German Army the admissions to hospital for venereal disease were in the ratio of 19.8 per thousand, or rather less than 2 men out of every 100. This fact entirely refutes the statement in the same letter that "the garrison towns of Germany are known to be the hotbeds of the most virulent forms of venereal disease," but in order to give full effect to the relatively minute ratio of the disease mentioned among German soldiers, I will quote the figures for the voluntary armies of England and the United States respectively from the same table. They are:—
"United Kingdom, 81.8 per thousand; United States, 178.72 per thousand."

I am, Sir, yours truly,
GEORGE T. SHEE, Secretary.
National Service League, 72, Victoria Street,
Westminster, S.W., April 5th, 1909.
P.S.—The figures for 1907 are:—Germany, 18.8;
England, 71.9; United States, 158.91.

#### **OBITUARY.**

SURGEON-COLONEL BACKHOUSE, F.R.C.S.

We regret to record the death of a well-known citizen of Dublin-Surgeon Lieutenant-Colonel

Backhouse, late of the Indian Medical Service, after a short illness. Colonel Backhouse, who was a student of the Royal College of Surgeons of Ireland, received his medical training at that school and at the Meath Hospital and Mercer's Hospital. He was qualified in 1868, and took the Fellowship of his College in 1882. His father was an Army Surgeon, and was attached to the 3rd Dragoons, and so it was only natural that the son too should seek to enter the military branch of his profession. Accordingly, shortly after he was qualified he entered the Indian Medical Service, in which he spent the greater part of his professional life. In India he won a distinguished position, and on several occasions his work was brought prominently to the notice of the Government of that country. He retired with the rank of Lieutenant-Colonel in 1897, and since that time he devoted himself to the task of assisting the work of the medical charities in Dublin. He took a very active part in the work of the Dublin Hospital Sunday Fund, and as a member of its visiting committee he was a well-known figure at the different hospitals. He was also a strong supporter of the Royal Medical Benevolent Fund of Ireland, and of the National Children's Hospital in Harcourt Street. By all these institutions and charities his loss will be deeply felt.

DR. THOS. CRAWFORD HAYES.

THE death of this gentleman occurred at his residence in Clarges Street, Mayfair, London, last week. Dr. Hayes was a gold medallist of Trinity College, Dublin, and graduated M.D.Dub. in 1875. He soon after proceeded to London, and was made a Fellow of the Royal College of Physicians in 1889. He was also an Hon. Fellow of King's College, and took up gynæcology as his speciality. At the time of his decease he was Emeritus Professor of Medicine of King's College, and a Consulting Physician to the King's College and Royal Free Hospitals. He also held appointments at the Evelina Hospital for Sick Children and the General Lying-in Hospital.

#### REVIEWS OF BOOKS.

THREE BOOKS ON CANCER. (a) THREE works on cancer lie before us, and it is interesting to compare them on their merits. first is a series of lectures on the pathology of cancer by Dr. C. P. White, which are full of scholarly information and illustrated with a number of excellent black-and-white plates. Dr. White uses the word "cancer" as covering all malignant growths, and we think, considering the modern trend of opinion, that he is justified in doing so. In the first part, on tumours in general the author essays a classification, which, if bold, is certainly very well done. Part II. deals with malignant growths generally, especially their characteristics, and modes of extension. Both these parts are brief and business-like. "Causation" is the subject of the third part, and we confess to finding it a little disappointing. We wish for a close study of the subject, and we get chiefly a résumé of opinions. The final section deals with the "Bearings of Pathology on Treatment," in which ancient and modern methods are discussed and criticised. Finally, there is an appendix, occupying nearly half the book, and consistent of illustrations. sisting chiefly of illustrations. As a sound abstract of modern views, these lectures are worthy of perusal.

Mr. Gibson's book is a conscientious study by a scientific man, approaching his subject from the statistical and biological points of view, and presenting a large number of interesting facts. It is certainly worthy of careful attention by those interested in the subject, and we shall await with interest the larger work, of which the present volume is only the fore-

<sup>(</sup>a) 1—"Lectures on the Pathology of Cancer." By C. P. White: M.A., M.D., F.R.C.S., Pilkington Cancer Research Fellow. London Shirratt and Hughes. 3s. 6d. net. 2.—"The Etiology and Nature of Cancerous and other Growths." By W. T. Gibson, A.R.C.S. London: John Bale, Sons, and Danielsson. 1909. 3.—"A Taeory regarding the Origin of Cancer." By C. E. Green. Edinburgh and London: William Green and Sons.

runner. We hope that the author will therein define more exactly the sources of the evidence he relies on. What we suffer from chiefly in regard to cancer is too wild, hypothetical, and half-true statements; and what we lack is definite information. For instance, all are agreed that cancer follows trauma in a certain number of cases. But how frequently there is such a relationship; what tumours most frequently occur, and in what sites, are merely matters of conjecture. Patients when they find a tumour think "they must have had a blow," and down in the hospital records goes, "History of Injury." Such evidence is worse than useless: it is misleading. We hope in this and similar matters Mr. Gibson will help us to more exact

The third book we have to deal with is also by a layman, but he, too, is of a scientific turn of mind, and his brochure is very suggestive. He approaches his subject from the botanical and industrial side, and cuts forward an assumption that cancer is due to a fungoid parasite and to the presence of sulphuric or sulphurous acid. Like many ingenious theories of cancer, it is *primá facie* plausible, but the author does not bring his charge home. Let him demonstrate his case, and we will be charmed to listen to what he has

to say.

#### SMALL-POX. (a)

Dr. RICKETTS states in his preface that for more than ten years he has been revolving the idea of writing a book on the diagnosis of small-pox, and we may truly say that his deliberation has amply justified itself, for the result he presents is unique. In the first place, the strict purpose of the book is to establish Dr. Rickett's theory as to the value in diagnosis of the distribution of the rash, and that he has done-satisfactorily. In the second place this book is unique in the value of the illustrations, which are so good that it is difficult to speak soberly about them. Both Mr. it is difficult to speak soberly about them. Byles's black-and-white photographs and the colour-photographs are as clear and realistic as anything we have seen, and the author is much to be congratulated on having secured an illustrator of such skill. For, as he himself says, without the illustrations to bear out his assertions, the demonstration of his theory would be almost impossible. As it is, it may be asserted that Dr. Ricketts has proved his point asserted that Dr. Ricketts has proved his point—namely, that the determining factor in the diagnosis of small-pox is the distribution of the rash, and thereby he takes us a long step forward in the solution of one of the most difficult of public health problems. Admittedly, the difficulty of nipping an outbreak of small-pox in the bud is the danger of mild cases being unrecognised, and yet to a practitioner at all acquainted with the characteristics of small-pox lesions, who knows how to appraise the value of the sites on which they appear, the problem of definite diagnosis is enormously simplified. We cannot here follow the argument for centrifugal distribution in detail, but it is carefully set out, step by step, in the book before us, and each step is abundantly illustrated, so that anyone who studies it carefully can hardly rise from the perusal without the conviction that his knowledge has been extended, clarified, and systematised, and his efficiency as a custodian of the public health definitely increased. It is a pleasure in these days of book-making to read such an able, sincere, and valuable work as that which Dr. Ricketts and Mr. Byles have given us.

SOURED MILK IN THE TREATMENT OF DISEASE. (b)

This little book of 32 pages is an amplification of a paper by the same author, which appeared in the Lancet of August 8th, 1908. In it he claims to set

London: Henry Glaisher.

forth, just so much of our present knowledge of lactic acid ferments as may be likely to be of assistance to the practitioner of medicine, in prescribing them in a scientific manner. It is divided into three chapters. The first chapter gives a brief account of autointoxication generally, and a more detailed account of intestinal putrefaction and the form of auto-intoxication which is produced by it. The manner of its recognition, and tests by which its amount can be estimated are also dealt with. Chapter II, is of special importance and value, for in it the author states how we may select a suitable preparation of lactic acid bacilli, either for the curdling of milk or for the acclimatisation of the organism in the intestines, from the many spurious commercial preparations in the market. The exact directions for use are carefully and lucidly described. The last chapter contains a list of the abnormal conditions for which the administration of lactic acid ferments may be employed. Some of these are diseases in which their value has been demonstrated, but their administration for others stands on a more questionable basis. We think, for example, that the author's enthusiasm has led him beyond the present state of our knowledge, when he includes neuritis and polyneuritis, progressive muscular atrophy, acute ascending paralysis, and chronic ill-health without any obvious cause, among the indications for this line of treatment. We would recommend anyone who intends to use lactic acid ferments, to first read this little book, for we feel sure that by thus acquiring a method of scientific therapeusis, he will be saved from much disappointment due to faulty methods of administration or the employment of inert preparations.

#### THE SOLAR SYSTEM. (a)

THE study of the solar system is not part of the medical curriculum, and may therefore attract the attention of those who have had a surfeit of Esculapian lore. The author's object has been to present the principal astronomical phenomena in a non-technical way, free from the mathematical embellishments that frighten the general reader. Thus described, few subjects possess such an overwhelming interest as the study of the heavens, and the reader is led on to familiarise himself with the awe-inspiring phenomena which are constantly recurring in space. Such a study is a useful "alterative" to the petty cares and worries of daily life. The author has accomplished in English what Flammerion long since did in French in the direction of generalising a know-ledge of these celestial wonders. Everybody, in the abstract, would like to know how and why the oceans rush hither and thither under the influence of the tides, why winter is characterised by cold, and summer by heat, why the moon is so inconstant, and so on. When we at last understand the means employed to estimate the distance of the sun and stars, we cannot but feel proud of our human intellect, which, limited though be its scope, is yet capable of bridging over the abyss, and of determining beforehand the exact phases of planetary oscillations. We cordially recommend this "popular astronomy" to the notice of our readers with energy and leisure enough to devise of things outside medicine.

#### DISEASES OF THE EAR. (b)

THE author has written a short practical account of diseases of the ear, specially intended for those who have not had an opportunity of devoting much time to the subject. The work is liberally illustrated with photographs of instruments which it is highly improbable that the reader-presumably a student or general practitioner-will ever use or require to recognise. Anyhow, the frontal mirror, with its central aperture, is quite old-fashioned. Most specialists aperture, is quite old-fashioned. nowadays make use of the French model of electric

reflector, with double eye apertures, and in any event it was hardly worth reproducing so familiar an object. In this connection the author would possibly have been well advised to "rub in" more thoroughly the ever-present risk of mastoid and cerebral complica-tions in middle-ear disease. They are mentioned, it is true, but not in a way that strikes the attention, and yet the general practitioner can make no more frightful blunder than to overlook symptoms pointing to mastoid or cerebral infection, since prompt intervention alone can save the situation.

MIND AND ITS DISORDERS. (a)

WITH all new text-books one naturally asks oneself, is the appearance of this work justified? There are books galore on the subject, and is a fresh one needed? In the case of Dr. Stoddart's "Mind and Its Disorders," we have no hesitation in saying "Yes" to both questions. Indeed, if we compare it with much of the stuff which fifteen or twenty years ago passed as authoritative writing on insanity, we cannot fail to be struck with the great gulf which has been bridged. But, even among current works, Dr. Stoddart's is destined, we believe, to take a high, if not a commanding place, because it is the product of clear, definite conception of the physiology and pathology of the mind, applied to clinical phenomena. We are aware that dangers lie in a too rigid application of logic to conditions so nebulous as many mental disorders, but to the student it is an inestimable boon to have a definite philosophy running throughout his reading and ward-work, and even when his philosophy becomes a little shaky, or definitely breaks down, the departure from the normal impresses him at least as much as consistency would have done. Without being a full and exhaustive book, the one in our hand contains all that is necessary for general practice or examinations, and if it is free from jaunty tales or spicy bon-mols, which we have come to regard as the stock-in-trade of works on "insanity," it is at least stock-in-trade of works on "insanity," it is at least full of good pathology and good sense. There are, naturally, points that call for criticism. For instance, while we agree with Dr. Stoddart that a great deal of hysteria following injury is put down as "traumatic neurasthenia," we do not agree with the suggestion that traumatic neurasthenia has no positive existence. It is a definite malady, typically seen after head injuries, and has its clinical features and its clinical course. It is not uncommon to find a patient who has had a severe blow on the head become precisely such a neurasthenic as Dr. Stoddart describes in Chapter XIII. But, taken as a whole, we warmly recommend this book to such as wish to acquire a clear, balanced view of the disorders of the mind.

#### APPLIED PHYSIOLOGY. (b)

It is very true, as the author observes, that students are very apt to store their knowledge of the various subjects in water-tight compartments, forgetting that physiology, for instance, is useful only in so far as it enables us to gain an insight into pathology—in other words they are taught the normal working of the, body by way of providing a standard whereby to gauge the abnormal.

Then, too, physiology gains immensely in interest when it passes from the abstract to the concrete, and the practical bearing of physiological data is explained and commented upon. In addition to this, the method throws much light on processes which would otherwise

of being practically applied is very small, and this admission raises the question whether it is desirable or necessary to burden the student's memory with endless theories and hypothetical explanations which are periodically abandoned every few years, their place being taken by others of equally ephemeral status. Such lucubrations have no practical scientific value,

respectfully urge on the examining boards the propriety of insisting only on a knowledge of applied physiology, leaving the rest to "pure physiologists." Were this made part of the curriculum, Dr. Hutchison's book would be exactly what students would require, and, even as matters stand, they would find its perusal of great assistance in grasping the main facts of physiology.

PHYSIOLOGY AND PATHOLOGY OF URINE. (a)

In his preface to the first edition, the author remarked:—"The foundations laid by pathological chemistry are ever changing; what is accepted to-day may to-morrow be merely 'as a tale that is told." That was four years ago, and the truth of the statement is well exemplified in the additions and revisions observed in the second edition. Additional subobserved in the second edition. Additional substances are dealt with, new methods of analysis are incorporated, and the difficult problems that present themselves in the interpretation of the presence of various abnormal products are honestly met. We should have welcomed a larger space than two pages devoted to micro-organisms. Dr. Dixon Mann's devoted to micro-organisms. Dr. Dixon Mann's thoroughness in his treatment of the subjects on which he writes is too well known to need mention, and this book is particularly worthy of him It is certainly a volume that should be read by every practitioner and student.

## MEDICAL NEWS IN BRIEF.

Congress on Alcoholism.
The delegates to the 12th International Congress on Alcoholism, which will be held at the Imperial Institute, London, on July 19th and following days, will be entertained at a reception by the Government. The committee of the Congress, of which the Dean of Hereford is Chairman, have received an intimation to this effect from the First Commissioner of Works. The reception will be held at the Imperial Institute on the evening of Monday, July 19th, and the arrangements will be made and the expenses defrayed by the Government. The letter also states that only non-

alcoholic drinks will be provided for the occasion.

The Foreign Office has invited the Governments of the following countries to send official representatives to the Congress:—The United States of America, France, Germany, Denmark, Norway, Sweden. Switzerland, Russia, Austria, Hungary, Roumania, Italy, Belgium, Holland, Uruguay, and Mexico. All these were represented at the last Congress held in Stockholm the Colonia of the Colonia Communication. holm two years ago. The Colonial Office has extended similar invitations to the Governments of all the selfgoverning Colonies. The Government of India is now being consulted by the India Office on the subject of appointing a representative for India. By permission of the Home Office, Dr. R. W. Branthwaite, the Inspector under the Inebriates Acts, will attend the Congress; so also will Lieutenant-Colonel McHardy, Chairman of the Prisons Commissioners for Scotland, and Sir George O'Farrell, Inspector of Lunatic Asylums in Ireland. The delegates will number nearly 2,000, of whom probably 500 will come from foreign countries and the Colonies. The Hon. President is the Duke of Connaught.

Liability for Medical Attendance.

The Isle of Wight County Court Judge on April 7th found that Mrs. Woodhall, of Roland Gardens, South Kensington, described as a lady of considerable means, was responsible for her sister's doctor's bill,

amounting to £37.

Whilst staying with friends at Yarmouth, Isle of Wight, in September last, the sister was thrown out of a motor-car and sustained a broken leg. A doctor

and they cumber the ground; in fact, we would (a) "Mind and its Disorders," By W. H. B. Stoddart, M.D., F.R.C.P., Assistant Physician to Bethlem Royal Hospital. With illustrations. London: H. K. Lewis. 1908. Price 12s. 6d, net. (b) "Applied Physiclogy," By Robert Hutchison, M.D., F.R.C.P., Physician to the London Hospital. London: Edwin Arnold,

<sup>(</sup>a) "Physiology and Pathology of the Urine, with the Methods for its Examination." By J. Dixon Mann, M.D., F.R.C.P., Physician to the Salford Royal Hospital. Pp. 324 and xiii., with 30 illustrations. Second Edition, revised and enlarged. London: Charles Griffin and Co., Ltd. 1908.

attended the young lady regularly, paying over fifty visits. From time to time defendant was consulted about the case. When the plaintiff sent in his bill the claim was repudiated.

On behalf of the plaintiff, it was argued that Mrs. Woodhall not only approved Röntgen-ray treatment when it was recommended by the plaintiff, but paid

for it.

Counsel for the defendant suggested that the host of the young lady should pay, but His Honour held that that was a very strong proposition. If hosts were to be held responsible under such circumstances it would do much to upset week-end visits, now so much in vegue.

His Herour gave judgment for the full amount claimed, with costs, holding that defendant had held herself out as responsible for the payment for her sister's medical atendance.

Feeble-minded Children,

AFTER consideration of the Report of the Royal AFTER consideration of the Report of the Royal Commission on the Feeble-Minded, the Special Schools Sub-Committee of the London County Council state that there are over 8,000 children of school age in London who may be affected by its recommendations:—Mentally defective, 6,559; epileptic, 316; mentally defective, and also blind, deaf, or physically defective, 250; imbecile, 663; under Metropolitan Asylums Board, 632. The Sub-Committee, who reported to the Education Committee of the Council on April 2th consider that a register of mentally defective April 7th, consider that a register of mentally defective children should be kept, and that observation homes should be established for doubtful cases.

Ebbw Vale Dispute.

A FURTHER complication has arisen in the Ebbw Vale Workmen's Doctor's Fund dispute. Recently the Victoria section of the payees refused to accept the result of the ballot which was taken to effect a settlement of the disagreement caused by the Cwm section dispute, and on April 3rd the Ebbw Vale section at a mass meeting took a similar attitude. A heated discussion took place upon the manner in which the last ballot had been taken, several of the speakers declaring that the issue had been so confused as to make it misleading and that the result was not binding on either party. Several resolutions and amendments were submitted to the meeting, the one ultimately carried being: "That another ballot, arranged by the workmen themselves, should be taken, and that the plain issue be for or against the re-instatement, and that the conditions be made binding upon all parties."

The Royal Colleges of Physicians and Surgeons have decided to add the University of St. Andrews to and Surgeons the list of institutions at which the curriculum of professional study required for the diplomas of the two Royal Colleges may be pursued, and whose graduates may be admitted to the final examination of the Examining Board in England on production of the required certificates of study. The Grammar School, Cheltenham, has also been added to the list of institutions recognised by the Board for instruction in chemistry and physics, and the Merchant Taylors' School, London, which is already recognised in these two subjects, has also been recognised in biology. On the recommendation of the examiners for the Conjoint Public Health diploma, the Royal Colleges have decided to revise the syllabus of the subjects required for both parts of the examination. The new syllabus will come into force on January 1st next.

Another X-Ray Martyr.

In the House of Commons on April 7th Mr. Hobhouse, Financial Secretary of the Treasury, speaking on behalf of the Prime Minister, informed Mr. Bowerman, the Labour member for Deptford, that a grant had been made from the Royal Bounty Fund to Mr. H. W. Cox, who recently sustained serious and permanent injuries in connection with X-ray research work.

Mr. Cox is a manufacturer of X-ray apparatus.

Mr. Cox is a manufacturer of X-ray apparatus. His experiments with the X-rays resulted in an attack of dermatitis, which necessitated the amputation of the larger portion of his right hand, and one of the fingers of his left hand.

After the operation on Mr. Cox, the King sent a gracious message of sympathy to Mis. Cox.

#### Sleeping Sickness.

It is reported that the spread of sleeping sickness in the German West African colony of Togo is assuming menacing proportions. The flies which carry the infection, Glossina palpalis and Glossina fusca, are being found even in the dry season at some distance from the bush, and in entirely dry districts. They have even been discovered less than a mile away from a road where hitherto it has been assumed that these insects were unable to live. In the district of Buemu sleeping sickness has become a danger for everybody, including Europeans.

#### Beard of Superintendence of Dublin Hospitals.

THE Dublin Gazette announces a new departure of the Lord Lieutenant of Ireland in appointing a practical nurse to a seat on the Board of Superintendence of Dublin Hospitals. A vacancy was caused by the resignation of the Right Honourable Thomas A. Dickson, and Miss A. M. MacDonnell, the lady appointed in his stead, has had a lengthy and notable experience in hospital work. A native of Kerry, Miss MacDonnell was trained in Sir Patrick Dun's Hospital, Dublin, and for 21 years she has been Lady Superintendent of the largest hospital in Dublin. During the late Boer War, Miss MacDonnell acted as matron in the Irish Hospital, South Africa, and received not only the medal for service, but the Royal Red Cross, from His Majesty, for special and distinguished services. The work of the Board is to pay periodic visits to the various hospitals in Dublin and to report upon their efficiency, and this is the first time a woman has been appointed to the Board of Superintendence.

#### Australia's Crusade against the Mosquito.

WE understand that Dr. Ham, Commissioner of Public Health at Brisbane, recently called together all the medical health officers of his department, in order to put before them evidence of the particular mischief wrought by the mosquito, and to urge them to action. The spread of filarial disease in Queensland is the new indictment against this pest. The filaria parasite is a small nematode worm, conveyed to the blood either by mosquito bite or by drinking water polluted by mosquitoes, and the conference was informed that 17 per cent. of the patients lately admitted to the Brisbane Hospital were found to have the parasite in their blood at first examination. Even the dreaded yellow fever was spoken of as a possibility, seeing that Brisbane possesses a little striped mosquito known to be a carrier of the disease. Dr. Ham believes it feasible to subdue the pest, if not to destroy it altogether, and towards this end he recommends, among other things the wire correction of materials and the stripes. other things, the wire-screening of water-receptacles and the draining of all stagnant pools.

#### Vital Statistics.

The deaths registered last week in the 80 great towns of the United Kingdom corresponded to an annual rate of 17.9 per 1,000 of their aggregate population, which is estimated at 18,457,600 persons in the middle of this year. In the preceding three weeks the rates had been 22.1, 22.1, and 19.8 Measured by last week's mortality, the highest annual death-rates per 1,000 living were:—From all causes, 25.9 in Dublin, 23.7 in 1 iverpool 22.8 in Preston, 24.4 in Oldham. 27.0 in Liverpool, 23.8 in Preston, 24.4 in Oldham, 27.0 in Wigan, 27.3 in Great Yarmouth, 28.1 in Warrington, and 30.7 in St. Helens; from measles, 3.1 in Reading and in Sheffield, 3.8 in Bootle, 3.9 in West Hartlepool, 4.6 in Wigan, 8.7 in Warrington, and 14.8 in St. Helens; from diphtheria, 1.1 in Huddersfield; from whooping-cough, 1.1 in St. Helens and in Swansea, 1.7 in Norwich, and 3.1 in Preston; and from diarrhosa, 2.9 in Wigan. One death from small-pox was registered in Bristol, but none in any other of the 80 towns. In London the total number of deaths from all causes fell from 24.0 per 1.000 of a fortnight Liverpool, 23.8 in Preston, 24.4 in Oldham, 27.0 in from all causes fell from 24.0 per 1,000 of a fortnight ago to 18.3 last week.

Gd. per line beyond.

Ex ÆQUALL—It is becoming a question of grave doubt whether, after all, researches into "mouse cancer" will eventually throw much light upon the cancer problem. There must be something very different from cancer as produced in the mouse and that which is seen in man, having regard to the fact that in the former the disease disappears spontaneously in as much as thirty per cent, of the infected mice.

THE BURNING QUESTION OF THE DAY!!

(Cremation contrasted with Burial.)

EXEMMATION.

Heat the furnace raging hot, better far consume than rot. Ashes clean and inoffensive, funeral much less expensive; And your relatives will save, money wasted on a grave. When it comes to be your turn, leave your orders for an urn. BURIAL.

Why boxed up, to decompose, and offensive to the nose? Poisoning air with gases vile, in "bad odour" all the while, Friends unhappy weep and grown

CLARRE.—On April 6th, at Magor, Monmouthshire, to the wife of John Stephenson Clarke, M.B.—a son.

COPER.—On April 9th, at 27 Thornton Hill, Wimbledon, the wife of Fleet-Surgeon Edward Cooper, H.M.S. "Bellerophou, of a daughter.

Harris.—On April 5th, at Oaklands, Rochdale, the wife of Heibert Harris, M.D., of a son.

Lamplough.—On April 7th, at Bredon, Alverstoke, the wife of Dr. Wharram H. Lamplough, of a daughter.

Last.—On April 5th, at Bletsoe, Littlehampton, the wife of C. E. Last, L.R.C.P., M.R.C.S.Eng., of a son.

LOW.—On April 5th, at 18d Harley Street, London, the wife of V. Warren Low, M.D., F.R.C.S., of a daughter.

NICHOLLS.—On April 9th, at 62 Queen's Gardens, Hyde Park, London, the wife of Frank J. Nicholls, M.B., B.C., of Estbourne, of a son.

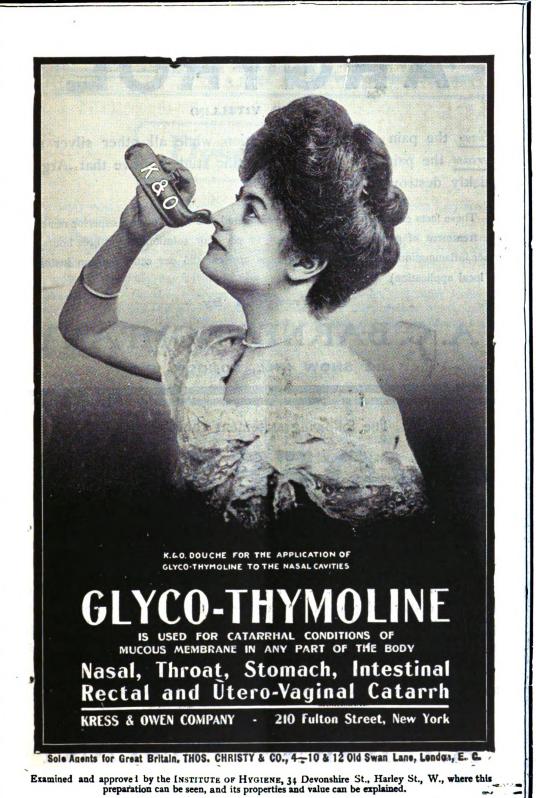

CAMERON YOUNG.—On April 4th, at Brightwell, Ipswich, the wife of Cameron Young, M.R.C.S., of a son.

#### Marriages.

WALLACE KIDSTON—FERGUSON.—On April 6th, at St. George's United Free Church, Edinburgh, Noel Wallace Kidston, M.B., Ch.B., son of the Rev. J. Wallace Kidston, 25 Earls Terrace, London, to Else, younger daughter of John Ferguson, wemyse Place, Edinburgh.

#### Beaths.

BOND.—On April 6th, at 37 Pepys Road, St. Catherine's Park.
London, Ella, wife of J. W. Bond, M.D., and daughter of the
late Colonel Edward Ramsden Priestley.
CRAWFORD HATES.—On April 5th, Thomas Crawford Hayes, M.A.
M.D., F.R.C.P., of 17 Clarges Street, Mayfair, London.
WEBS.—On April 8th, at 113 Maida Vale, London, Frederick
Ernest Webb, M.R.C.S., L.R.C.P., son of the late Thomas
Ernest Webb, formerly of Bungay, aged 77.

Have you noticed that an injection or instillation of

# ARGYROL

(SILVER VITELLIN)

<u>relieves</u> the pain of local inflammation, while all other silver salts <u>increase</u> the pain? Moreover, scientific studies prove that Argyrol quickly destroys gonococci.

These facts explain why Argyrol is considered, the world over, a superior remedy in the treatment of gonorrhœa (injection of 10 per cent. solution every three hours) and other inflammations of the eye, throat, nose and ear (25 per cent. solution instillation or local application).

Produced by

# A. C. BARNES COMPANY

32 SNOW HILL, LONDON, E.C.

The following statement concerning

# OVOFERRIN

(IRON VITELLIN)

is a copy from the official records of the largest clinic in Germany where the remedy has been in continuous use for more than four years:

"Ovoferrin is an easily assimilable, well tolerated remedy which does not disturb digestion or cause constipation, but improves the appetite, digestion and general nutrition, and produces steady and progressive increase in the percentage of hæmoglobin and red corpuscles."

Ovoferrin is furnished by chemists, on prescription, in twelve ounce bottles. The dosage is one tablespoonful in a wine-glass of water or milk three times daily.

Produced by

# A. C. BARNES COMPANY

32 SNOW HILL, LONDON, E.C.

# Dyspepsia.

Probably most cases of indigestion are due to the inability to convert amylaceous foods into assimilable forms.

Taka-Diastase has been proved to be the most potent—as well as the most convenient—substitute for ptyalin and amylopsin when these are deficient. It is a pure vegetable amylolytic ferment, capable of rendering soluble 150 times its weight of dry starch in ten minutes, and much more in a longer period.

Taka-Diastase is far more effective than the best malt extract and other forms of diastase, and is active in acid conditions of the stomach or in the presence of tea, coffee, alcohol, etc. (see articles in *The Lancet*, May 7th, 1898, and *The Boston Medical and Surgical Journal*, April 6th, 1899).

Taka-Diastase retains its activity in all climates. The dose is from  $2\frac{1}{2}$  to 10 grains

# Antiphlogistine

(Inflammation's Antidote).

Applied from ear to ear as hot as can be borne comfortably by the patient, depletes the enlarged lymph glands, guards against the passage of toxines into the circulation and reduces the liability of Mastoiditis, Middle Ear and Laryngeal complications in Tonsillitis, Scarlatina, and other diseases of similar nature.

The dressing of Antiphlogistine must be at least an eighth of an inch thick, covered with a plentiful amount of absorbent cotton and held snugly in place by a bandage.

## Notes and Comments.

Christian Science at Sutton.

CHRISTIAN Science can hardly be congratulated on the show that it made in the case reported last week from Sutton. A Miss Latour, from Guatemala, had the misfortune to

contract tuberculosis of the lungs when living at Kew, when she was attended by Dr. Bellamy, and under his treatment she made considerable improvement. Here, then, was the opportunity for the Christian Scientist to step in and complete the good work Dr. Bellamy had begun. Unfortunately for the cult, the improvemnt was not maintained, and Miss Latour left her home and went to stay with friends at Sutton, "to get away from doctors"—to use her own expression. The disease progressed, her friends became alarmed, and Dr. Hooper of that place was sent for. He was politely informed on arrival that he was sent for "to keep within the law." Naturally and very properly Dr. Hooper declined to play the part of scapegoat, and advised that Dr. Bellamy should be sent for, if medical attendance were needed. In evidence at the inquest, Dr. Bellamy explained that when he ceased his attendance there was no active tuberculous disease, and that he held that no medical man should give a certificate under the circumstances. The friends had told him that there was no such thing as pain and no such thing as death. Un-happily in the case of the deluded lady the latter opinion was disproved by the sequence of events, as she passed away shortly afterwards.

A Qualified Success.

AFTER hearing the evidence at the inquest, the Coroner's jury found that death was due to natural causes, and that there had been no criminal neglect on the part of any-

one, the friends having done their best according to their belief. But they added a rider to the effect that they were of opinion that, had Miss Latour received proper medical advice, instead of trusting to Christian Science treatment, her life might have been considerably prolonged. This strikes us as being as sensible and scientific a verdict as could be given under the circumstances. The folly and chicanery of Christian Science will find a natural quietus if left to expend themselves on the weaked-minded and more credulous portion of the community. The flames of "persecution," police court and assize proceedings, and so on, are only calculated to give a lurid advertisement to a procedure which, while partaking of both elements. inclines more to silliness than crime. In really bad cases of neglect, criminal steps may be necessary, but in cases such as that of the unfortunate Miss Latour, in which an adult person has been blinded and led away by the sophistries and pompous

platitudes of Christian Science practitioners, it is impossible to blame anybody who survives the catastrophe, except the practitioners. And while unqualified practice is allowed by the law, it is only inviting odium and suggestions of self-interest to advocate criminal prosecution of practitioners of the cult.

Accident Hospital.

An interesting little medical dispute is being carried on at Barry. That place owns what is described as the only hospital in the United Kingdom maintained wholly out of

the rates—a description which is hardly accurate when one considers the large number of fever hospitals throughout the country which are rate-supported. Such hospitals differ from the Barry hospital, however, in that, whereas at the former there are special salaried medical officers, at Barry the medical staff is honorary. The argument has been adduced that, under the circumstances, all medical men in the town should be members of the staff, or, at least, should be able to attend their own patients when inmates of the institution. right is claimed by them as ratepayers. As it is, there is a special staff to which, as the members are *ipso facto* hospital surgeons, a certain prestige is attributed. The point was considered by the local division of the British Medical Association, which decided in favour of the application. The matter was then referred to headquarters, and efforts were made to ferred to headquarters, and efforts were made to effect a compromise, without, however, securing The matter has been referred to the Hospital Committee of the Association. We cannot say that, in the absence of special knowledge, we are competent to express a decided view one way or another, but it seems to resolve itself largely into a matter of local convenience, for we conceive it possible that, with a large number of honorary medical officers, the administration of the hospital would be very difficult to carry out efficiently.

What is Brandy?

THE question, "What is brandy?" seems determined to agitate society for some time to come, much in the same way as the equally vexed question concerning whisky. In the evidence taken before the Royal Commission

on whisky and other potable spirits, the proper definition of brandy has taken a prominent position. One gentleman took the ground that analysis should always be made the supreme test of procedure, as it is at present. In support of that view he advanced the interesting but imperfect analogy of the difference between Welsh and Australian mutton, which could not be determined by chemist's analysis. In the same way he did not think that

laboratory investigation could settle whether a given brandy came from Cognac or not. So far as medicine is concerned, the definition of French brandy has long since been fixed under the heading of "Spiritus Vini Gallici" as "spirit distilled from French wine." Later, in 1898, it was further French wine." Later, in 1898, it was further described as "a spirituous liquid distilled from wine and matured by age. and containing not less than 36½ per cent. by weight, or 45½ per cent. by volume, of ethyl hydroxide." The fact of these variations from time to time in the Pharmacopæia definitions clearly shows that the compilers' views were liable to alteration. When brandy is ordered as a drug their view must be final, and it doubtless expresses their opinion as to what constitutes brandy when not ordered as a drug.

#### Featureless Brandy.

DR. LETHERLAND TEED, the wellknown analyst and authority upon drugs, stated that although he had never tasted or analysed mistura spiritus vini Gallici, yet he under-

stood it to be a kind of egg flip. Although Cognac brandy was still being imported, he understood that large quantities of wine were being turned by a process of fractional distillation into featureless spirit. If such a product was recognised as brandy it would be impossible for an analyst to distinguish between it and other featureless spirits made from beetroot, molasses, potatoes, corn, and so on, which it was well known were being palmed off on the public as brandy. Dr. Teed's view of brandy is of importance. He defines it as a spirit distilled from the produce of the grape in a pot still. The word "brandy" occurred in an Act of Parliament 100 years ago, when there were no fractionalising or patent stills. It seems likely that most medical men will heartily endorse Dr. Teed's claim that those who ask for brandy should be entitled to a spirit distilled from wine in a pot still A further safeguard could be obtained by a Government stamp guaranteeing the origin of all such spirit, were such a thing practicable.

Our New Army Column.

WE have much pleasure in calling the attention of our readers to a new feature in our correspondence. A reference to page 411 will show a column under the head-

ing of "Military and Naval Medical Notes," which will in future appear weekly or otherwise, as circumstances may require. The contribution comes from the pen of a distinguished military correspondent, in whose trustworthiness and accuracy of information we place implicit reliance. From long experience we fee! confident that this new departure will be welcome to a large number of readers who are interested in military and naval matters in various parts of the world, and whom it is difficult to keep in comprehensive touch with that particular branch of medical life otherwise than through the agency of a specially qualified correspondent. We need hardly add that authentic military and naval news will always be a welcome contribution to the Editor's box.

#### LEADING ARTICLES.

#### PAY PATIENTS AND VOLUNTARY HOSPITALS.

THE question of the relation of the voluntary medical charities to the medical profession has been a matter of recurrent controversy for at least a couple of generations. That the matter has never

been brought to a head is possibly, or probably, due to the lack of effective organisation on the part of medical men. To some extent the latter defect is being remedied, and it is to be sincerely hoped that, with the development of a common collective policy and effectual basis of action, the question of the proper relation of charitable hospitals to the medical profession will be amicably and impartially decided. It is to be regretted that the powers of the General Medical Council do not permit of that august body dealing with a matter in which the welfare of the medical profession is so intimately concerned. There are other professional organisations, however, to which we may turn for help. notably, the various defence unions and the British Medical Association, which has of late devoted a not inconsiderable amount of attention to the question. The publication of a "warning notice" concerning certain vacant hospital and other appointments marks a practical step in the direction of the principle of collective defence and protest. It may be hoped that the Association will before long take into serious consideration the question of the payments of patients to voluntary hospitals. If there be any truth in the outcry of the general practitioner against hospital competition, it is obviously multiplied and materialised when presented in the shape of a paying patient in the wards of a hospital built, organised, endowed and maintained by money given by charitable persons for the specific object of relieving the sick poor. To use charitable funds, earmarked for that clearlydefined object for the purpose of making profit raises a delicate legal question as to the responsibility of the governing board that sanctions such a transaction. The whole matter of paying patients was discussed by a speaker at the London Nursing and Midwives Conference, held in London last week. Amongst other things, he pointed out that, whereas the poor and the rich were able to get the best possible modern medical treatment, the one in well-equipped voluntary and State hospitals and the other in private nursing homes, the middleclass individual of moderate means, on the other hand, was inadequately provided for. Practically, in time of sickness, such a patient was obliged to face his illness at home or to resort as a free or a paying patient to a hospital. The disadvantages of the first-mentioned courses are obvious, while the third involves injustices of various kinds that have long been recognised and protested against by the general practitioner. When a patient capable of paying moderate fees resorts to the pay wards of a voluntary charity, he is giving rise to a threefold injury. First, he is displacing a poor person, that is to say, one of the very class for whom the hospital was primarily provided; secondly, he is depriving the outside medical practitioner of a source of income to which he is justly entitled; thirdly, he is placing the board of governors of the particular institution to which he hands his money in the invidious position of diverting charitable trust funds from their original purpose. While the motives of hospital authorities are transparently honest, and their sole object is obviously to add to the funds of the charity with which they are connected, it is nevertheless fairly apparent that their action may involve them at any moment in an

undesirable position as regards their legal responsibilities. The suggestion of the speaker at the Conference that the legality or otherwise of patients' payments to voluntary hospitals should be made the subject of a friendly test action is well worth serious consideration. It is difficult to imagine any way of arriving at the truth of the matter otherwise than by a formal decision of the law courts. The friendly test action is a means of defining doubtful powers and responsibilities that is often resorted to by executors and heirs of estates. There is no apparent reason why it should not be adopted in the present instance. Either the patients' payments to voluntary charities are legal or not legal. If shown to be legal, members of hospital boards that accept such payments may continue the practice with confidence; if not legal, then they will take steps forthwith to put an end to the system, and a rock of offence will be removed from the path of the medical profession. It was further suggested that the friendly test action might come with advantage from either one of the Medical Defence Unions or the British Medical Association, and the suggestion appears to be an excellent one. By this simple expedient it is not impossible that the whole of the longstanding dispute between the voluntary charities and the medical profession would be settled out of The precise method of bringing such an action could safely be left to the lawyers to arrange. All that the test action would propose to ascertain is whether the acceptance of payments by patients by a voluntary medical charity, where such payments have not been expressly sanctioned in the document of foundation, does or does not constitute a misdirection of a charitable trust. If the matter be put in a reasonable and temperate way to the board of management of any great hospital that has adopted the principle of pay wards, it is not improbable that they would willingly accept the opportunity of defining their exact powers, and possibly of escaping from a false position of which the consequences might at some future time prove of an embarassing nature. From many points of view the suggestion of the test action meets the wants of the case in a peculiarly appropriate way. The idea is too good to be lost, and it is to be hoped that before many months are gone by, either the British Medical Association or some other professional body will have taken steps to reduce the suggestion to a practical issue.

#### MEDICAL MEN AND FRIENDLY SOCIETIES.

LAST week the Annual Conference of the Friendly Societies' Medical Alliance was held at Darlington. This Alliance comprises the medical associations which exist in connection with the great friendly societies throughout the country, and once a year representatives from each gather to discuss questions of mutual interest. These questions are so closely associated with one phase of medical practice that the profession cannot afford wholly to neglect the views held by the Alliance, whether or not it agrees with them. The President for this year, Mr. J. E. Wood, of Darlington, gave the customary address, and stated the line which, in his view, the Alliance should take in regard to the matters of controversy before it. We gather from what was said that the medical associations are

not so numerous nor so powerful in the North of England as in the South, for it seems that the Darlington Association is only seven years old, yet stands fifth in point of numbers of those affiliated to the Alliance, and Mr. Wood dwelt on the necessity of co-operation and combination if the movement were to grow and be placed in a secure position. He then proceeded to discuss the burning question of their relations with their medical officers, and he admitted that forces were still operating against them. Now, for the friendly societies we can truthfully say that we entertain a sincere admiration. The members are drawn for a large part from that excellent class in the community, the hard-working artisan, and their affairs are managed, as a whole, with a prudence and administered with an intelligence which are calculated to show that all wisdom does not reside in the classes which have no need of the aid of such societies. Founded on the principle of thrift, and taking a stand independent of State aid, the friendly societies stand as a model of what can be done by mutual support among the workers of the country. We cannot help regretting that the Government were not able to make the receipt of a society's pension a qualification in itself for receiving the five shillings a week which now is given only to those who have no assured source of income. Yet, while regarding the societies with all friendliness, we must join issue with them with regard to their medical policy, and we are glad to hear the President admit that "forces" operating against them on this score. the first place, we are surprised that the members are unable to recognise the fairness of insisting on a wage-limit in dealing with the members who contract for medical attendance. It is possible for anyone, whatever his income, to join a friendly society, and by keeping up his payments to be entitled to medical attendance whenever he is ill. Now, it is generally recognised that these societies are so stable and form so good an investment for surplus money, that many people of quite good position join them, and thereby become entitled to their benefits. While it is fair and just that a man should draw sick pay in proportion to the premium he pays, it is neither fair nor just that a member of a society can obtain medical attendance at Friendly society rates when he can well afford a doctor's normal rate of fees. Doctors, like other business people, have to take work in bulk more cheaply than when it comes in driblets, and they are able to make a low rate of charge to members of friendly societies for that reason among others. But the story by no means ends there. The whole theory of medical fees is that a person shall pay according to his means, and a well-to-do patient gets just the same advice for half-a-guinea as a poor man at half-a-crown. The system may be illogical, but if a better one can be suggested we shall be glad to learn it. Certainly, it is not that because a doctor is prepared to make special rates for people unable to pay adequate fees that he shall take everybody who likes to join with them at the same inadequate figure. The argument has only to be stated to bear its own refutation. No doubt it is a great incentive to people to join friendly societies that they know they can get

their medical attendance for a few shillings a year, but in the case of the better-to-do, who can afford a doctor's ordinary fees and yet wish to join a society, it is quite possible to exclude them from medical benefits, or to impose a higher rate on them. It is a great advantage to a friendly society to contain not only the artisan class, but most of the well-to-do tradesmen and clerks in a neighbourhood, but that advantage should be gained by the inherent soundness of the financial position of the society, and not by offering the special terms for which a medical man is prepared to attend the poorer members. Mr. Wood admitted that there was room for improvement between some associations and their medical staffs, but while he counselled that these difficulties should be dealt with in a sympathetic manner, he stood for a pretty uncompromising assertion of the rights of the societies. It is particularly significant that a resolution that "this Conference cannot at any time recognise any decision accepting a wage-limit for the attendance of a friendly society doctor" was passed without discussion. While such is the attitude of the Conference, we fear the end of the friction is yet a long way off.

#### CURRENT TOPICS.

The Value of Meat Import Regulations.

THE value of the recently-introduced legislation anent the regulation of meat imports has been amply vindicated by the report of Mr. James McPhail, Chief Food Inspector to the Hull and Goole Port Authority. In his first recital of his experience of the third section of the Public Health (Foreign Meat Regulations) Act, 1908, he reported extensive seizures of unsound meat from the Continent. Much of this pernicious stuff bore the label of the Government of the source of origin entitling it to be admitted, but large quantities thus guaranteed as wholesome were exported or destroyed as unfit for human food. The details of the seizures are reassuring as regards the vigilance of the inspectors and the value of the Act, but they are, on the other hand, extremely disquieting as indicating the mass of dangerous infection that must year by year be sent into our ports by unscrupulous foreign meat importers. In one case a quantity of so-called sausages sent in a barrel from Copenhagen were found to consist of scrap meat stuffed into the large bowel of an ox! Of four unlabelled pigs, one carcass was tuberculous and had the glands of the neck removed; another showed peritonitis; a third had the vertebræ badly formed and there had been dropsy. During the quarter large quantities of offal from calves, sheep and pigs were landed at Hull bearing the Government inspection mark, which was supposed to guarantee it as fit for food. The inspectors found large numbers of livers affected with parasites, such as immature tape-worms and flukes. One of the most important matters arising out of the Hull report appears to be the fact that, Liverpool having obtained through the Local Government Board a relaxation of the restrictions, the inevitable consequence of any such inequality would be to divert the meat trade from Hull and other stringentlyguarded ports to Liverpool, with results that could hardly fail to be inimical to the national health. The supreme importance of an absolutely uniform administration of the Act by port authorities is obvious, and the report of Mr. McPhail may be commended to the careful attention of the Local Government Board.

Compulsory Irish at the National University of Ireland.

THERE is in Ireland at the present moment evidence of the existence of a tendency on the part of many, otherwise level-headed men, to allow their sentiments to outrun their practical instincts. Perhaps in other countries, where everything gives way to the exigencies of material prosperity, some of this tendency would be no disadvantage, but in Ireland, of all places, where sentiment has always run rampant, it is far more necessary to decry than to encourage its exaggeration. For this reason we welcome the utterances of General Sir William Butler at the prize-giving ceremony at Rockwell College during the past week. Speaking of the possibility of supplanting English by Irish in Ireland, he drew attention to the fact that in Ireland they were within four hours' steaming on one side and four days' steaming on the other side, of millions of English-speaking people. He did not see, therefore, with these enormous masses around them, who for all purposes of life and all professions only knew the one tongue, it would be practicable to make such a change. On the other hand, he saw no reason why Irish should not take the place that Latin did in the Middle Ages, when it too ceased to be the language of the mart and of commerce. He was no believer in compulsion, and he did not understand why this country (Ireland), which had been for eighty years protesting against compulsion, should now advocate it. Is it too much to hope that Sir William Butler's practical utterances will produce the effect their importance warrants?

#### A Sanitary Oath.

For years past we, in common with the rest of the British medical oress, have been preaching against the ordinary form of taking the oath by kissing the book. A more offensive object to approach to the lips than the Testament generally proffered to witnesses in petty sessions or coroners' courts one can scarcely imagine. Smeared with the grease of decades, inoculated with the infections of thousands, it is hardly questionable that diseases of the most noxious description have been transmitted by its agency. To mention no others, syphilis, diphtheria, and influenza must frequently have been transmitted in this way. It seems likely, however, that all this will soon be changed. The Oaths Bill, which passed through the Standing Committee of the House of Commons before the recess, aims at substituting the Scottish form of oath for that by kissing the book. This form-taking the oath with uplifted hand-has for a considerable time been a legal alternative to the other in our courts of justice. The Oaths Bill, however, seeks to make it the only legal form, and to ensure that the oath shall always be administered in the same way. It seems quite likely that the Bill will become law, and thereby put an end to a custom at once revolting to taste and dangerous to health.

Nursing in India.

WE are glad to learn that that excellent institution, Lady Minto's Nursing Association, continues to flourish and to be appreciated by the Anglo-Indians of Northern India and Burmah. In old days, Indian residents who fell sick suffered much from the need of skilled nursing, and it is now a good many years since the Up-Country Nursing Association was started to provide skilled nursing for the English in Northern India. The work of the Association rapidly increased, and a few years ago, owing to the interest shown by the wife of the Viceroy, its scope was greatly enlarged, and the title of the Association changed. The Association is most careful in its choice of nurses, and, we understand, pays them adequate remuneration, and sees that they are comfortably housed. At present three superintendents and forty-four nurses constitute the staff. Last year 338 cases were attended, of which 103 were cases of enteric fever. The income of the Association is in part derived from fees earned by the nurses, and in part from voluntary contributions from subscribers, who pay according to their salaries, and have first claim on the services of the nurses, and at a lower rate than non-subscribers.

The Tuberculosis Campaign in Ireland.

It is now several years since the project of erecting a joint sanatorium for the County and City of Cork was first inaugurated, at the instance of the local branch of the National Association for the Prevention of Tuberculosis. Many unforeseen difficulties arose, chiefly springing from the question of a suitable site, and for some time it seemed as if the project would have to be abandoned. Last year, however, owing to the generosity of a member of the Joint Committee, Mr. Brazier-Creagh, a free site, with two hundred acres of land, in a suitable situation as regards soil and shelter, was presented to the committee. Last week her Excellency the Countess of Aberdeen carried matters a step further by laying the foundation-stone. All the sanitary authorities of the county and city-twenty-eight in number-are contributory to the scheme. It has been decided, for reasons with which we are unacquainted, to erect one compact building rather than a series of chalets. The total outlay is expected to be about £12,000, and accommodation will be provided for seventy-seven patients. Cork is the first county in Ireland to found a sanatorium, and the experiment will be watched with interest, since there is some risk that the importance of preventive work may detract attention from curative measures.

#### PERSONAL.

AT Haslar Hospital the following distinctions have been conferred on the class of Surgeons-on-Probation: The Gold Medal on Surgeon McW. A. H. McKirrow, M.B., Ch.B.Aber.; the Microscope on Surgeon F. G. Hitch, late of the London Hospital; and the Silver Medal on Surgeon J. Glaister, M.B., Ch.B.Glasg.

- DR. MATTHEWS BROWNE has been appointed a Justice of the Peace for the Borough of Eastbourne by the Lord Chancellor.
- MR. H. A. T. FAIRBANK, M.S., F.R.C.S., of Charing Cross Hospital, has been appointed Surgeon to the Miller General Hospital.

THE Hon. John McCall, M.D., has been appointed Agent-General for Tasmania in this country. He enters on his duties on May 1st next.

- DR. ARRIGO TAMASSIA, Professor of Forensic Medicine, at the University of Padua, has been appointed by the King of Italy to be a Senator of the Kingdom.
- Dr. A. S. BOSTOCK, of Chichester, has received a handsome testimonial and cheque from a large number of friends and patients on retiring from practice in that town.
- DR. JOHN CUTHBERTSON, of Droitwich, and Dr. Cordley Bradford, of Acocks Green, have been appointed Justices of the Peace for the County of Worcestershire.
- Dr. F. M. SANDWITH, Gresham Professor of Medicine, is giving a series of lectures this week, at Gresham College, on "Cancer," and also on some tropical diseases.
- DR. FRANZ RITTER VON HABERTER has been appointed to the posts of Ministerial Councillor and Medical Referee to the Austrian Ministry of the Interior, to succeed the late Dr. Daimer.

THE Lccal Government Board have approved the appointment by the St. Pancras Borough Council of Mr. J. K. Colwell as local Public Analyst in succession to the late Sir T. Stevenson, M.D.

WE regret to record the death, after a prolonged illness, of Lady Brunton, wife of Sir Thomas Lauder Brunton. We are sure that the sympathy of the profession will go out to Sir Thomas in his great bereavement.

THE LORD MAYOR, accompanied by the Sheriffs, will visit St. Bartholomew's Hospital on Friday, May 7th, at 3 p.m., to open the new Pathological Blocks. The ceremony will take place in the Great Hall of the Hospital.

PROFESSOR G. R. MURRAY, of Manchester, will open a discussion on "Diseases of the Thyroid Gland" at the Hunterian Society to-night at 8.30 p.m. Sir Victor Horsley and Mr. James Berry have promised to take part.

THE delegates of the Common University Fund of Oxford University have appointed Dr. Joseph F. Payne, Honorary Fellow of Magdalen College, to give six lectures on "The History of Greek Medicine up to the Age of Hippocrates," at the schools, on Wednesdays and Fridays, at 5.45 p.m., beginning on May 5th.

- Dr. David M'Kail, M.D., D.P.H., has been appointed by the Governors of St. Mungo's College, Glasgow, lecturer on Forensic Medicine and Hygiene, and also cn Public Health, in succession to Dr. Hugh Galt, Dean of Faculty in St. Mungo's College.
- SIR WILLIAM MCGREGOR, the newly-appointed Governor of Queensland, entered the Colonial Office service as Government Medical Officer at Mauritius. He was next promoted to Fiji, and it was while here, now over a quarter of a century ago, that he caught the eye of Lord Stanmore. From Medical Officer his administrative ability secured for him the Governorship of British New Guinea, where he remained for ten years. Thence he was appointed to Lagos, and after his term of office there he was appointed to Newfoundland.

## A CLINICAL LECTURE

ON

#### RENAL CALCULUS.

By ANDREW FULLERTON, M.D., F.R.C.S.,

Honorary Assistant Surgeon to the Royal Victoria Hospital, Belfast, and to the Belfast Hospital for Sick Children.

PART I.

GENTLEMEN,—The atiology of renal calculus is somewhat obscure. It may be that a foreign body, somewhat obscure. It may be that a foreign body, a little piece of necrotic tissue, a minute blood-clot, a parasite, or some substance or body abnormally situated in the kidney, may give rise to a nucleus, which, when once formed, tends to increase in size and become a calculus. Ebstein believes that the first step in the development of a calculus is the formation of an organic framework. The composition mation of an organic framework. The composition of the urine is probably of more importance. Thus, an alkaline condition of urine predisposes to the formation of phosphatic calculi, the urine of a gouty person is liable to deposit uric acid, and there are certain conditions of ill-health in which crystals of oxalate of calcium are liable to be deposited from the urine. Again, it is well known that in certain districts stone is much more common than in others. In tropical countries, where a large portion of the moisture of the body is got rid of by evaporation, the urine is likely to become concentrated, and to deposit some of its more insoluble constituents. In India, for instance, stone is one of the most frequent complaints that the surgeon is called upon to freat. In the North of Ireland, from which we draw most of our clinical material, stone cannot be said to be very common. The affection is certainly met with more frequently in some parts of England than it is with us. It is likely, also, that certain articles of food and drink may predispose to the development of calculi. In this connection it is only necessary to mention wines, hard drinking water, and vegetables, such as sorrel, rhubarb, &c., which contain calcium oxalate.

Origin of Renal Calculi.—Calculi originate in the kidney or in its pelvis. In new-born children, a granular deposit, composed of urates, is frequently found in the kidneys, but this is soon washed away when the urinary function is properly established. In a similar way, in later life, small particles of undissolved salts may be deposited in the kidney or its pelvis, and fail to be washed away, thus giving rise to a stone which, when once formed, tends to increase, until it may attain a very considerable size. As a rule, it rarely exceeds a small marble in size, but stones which entirely fill the renal pelvis and calyces

are occasionally seen.

Chemical Composition.—Renal calculi may be divided according to their chemical composition, into three great groups. Those of the first group are composed mainly of uric acid or urates; those of the second group, of oxalates; and those of the third group, of phosphates. In addition to these common varieties, calculi composed of cystin, calcium carbonate, and some other substances, are, in rare instances met with. It is generally stated that uric acid calculi are those most commonly met with; but from my own experience, I should be inclined to give the premier place to those composed of oxalate of calcium. It must be understood that these calculi are not infrequently mixed in composition, uric acid, for instance, being often associated with oxalates or phosphates. Similarly, a calculus composed principally of calcium oxalate may be mixed with uric acid, urates, or calcium carbonate. Phosphatic calculi, likewise, are rarely pure. It is well to have a simple test to differentiate the various calculi usually met with, and I have found the following method, which

is in common use, satisfactory. The calculus is cut and a scraping is taken from each layer. To this isadded a little water in a test-tube, and heat applied. If the fragment dissolves, it may be urates, cystin, or xanthin. If it does not dissolve, it may be oxalates, phosphates, or carbonates. Add a few drops of HCl, and heat. If it dissolves with effervescence, it is composed of carbonate; if it dissolves without effervescence, it is either phosphate or oxalate. Now add a few drops of ammonia solution. If a precipitate forms and is re-dissolved by acetic acid, phosphate is present. If the precipitate is not re-dissolved by acetic acid, oxalate is present. If the scraping does not dissolve either in water or in HCl, add to it a few drops of HNO<sub>3</sub>, and evaporate to dryness in a porcelain capsule. A yellowish-red residue rendered violet by ammonia solution, or dark blue (disappearing on heating), on the addition of caustic potash or soda; denotes uric acid. Uric acid, urates, cystin, and xanthin completely melt away on heating on platinum or mica foil. If cystin be present, the characteristic: crystals may be seen on evaporating a solution of it in water.

Characters of the Calculi.—The uric acid calculus is smooth or finely granular, is hard in consistence, and is of a yellow, reddish brown, or greyish colour. Oxalate calculi are brown or grey in colour, and may be mulberry-shaped or smooth. They are hard in consistence. Phosphatic calculi are white, and relatively soft. Cystin calculi are generally small, smooth, round, and yellowish or white in colour. They are soft, and on section show a white lamellated appearance. Xanthin calculi are brownish or reddish, smooth, hard, and lamellated on section.

The size and shape of renal calculi are influenced, to a large extent, by the cavity in which they are developed. Those which are formed in the calyces or pelvis of the kidney are moulds of these parts, and, consequently, round or branched in form, while those which have been long in the ureter are likely to be narrow and elongated. If several calculi are present, they may present facets at the points of contact.

Effects of Calculi on Surrounding Tissucs.—A calculus acts as a foreign body, and, consequently, irritates the tissues in which it lies. If it remain aseptic, chronic inflammatory changes occur in the renal parenchyma. If, however, sepsis occurs, suppurative pyelitis or nephritis may take place and go-on to complete destruction of the kidney. The least that is likely to happen is a localised interstitial nephritis. If the calculus produces obstruction, hydroor pyonephrosis may result, or the kidney may undergo complete atrophy without dilatation. A pyonephrotic kidney may leak into the surrounding tissues, giving rise to a perinephritic abscess. This may discharge externally or into the intestine. The other kidney may, if healthy, hypertrophy or become infected from the bladder. If already calculous like its fellow, if will run great risks of ascending infection from the blackler. This has an important bearing on treatment. The presence even of an aseptic stone is a menace, not only to the affected kidney, but also to the sound one. Statistics were collected by Legneu, who showed that in 50 per cent. calculi were present in the opposite kidney, while in the remaining cases, the second kidney was affected by sclerosis, or suppuration, or hypertrophy, or atrophy, or cystic degeneration, or some combination of these processes. Further, prolonged

suppuration in one kidney is likely to give rise to

amyloid changes in the opposite one. Symptoms of Renal Calculus.—A case upon which I recently operated in the wards is a fair example of this condition. He was a male, æt. 29. Last September, he had a severe pain in his right lumbar region which radiated down the front of his abdomen and into his right testicle. The attack lasted several hours. From this period up to February, he had attacks about every month, but since February he had had them every fortnight. During the attack, he complained of frequency of micturition, but says that there was no blood in the urine. The specimen of urine which he supplied looked clear, but on microscopical examination, blood cells were found in small quantity. On cystoscopic examination, the right ureteric orifice was seen to be rounder and larger than usual, with many small blood vessels surrounding it. The urine from this orifice contained a fair quantity of albumin, and numerous blood corpuscles. Its specific gravity was 1010, and its reaction acid. The specimen from the left side was also acid, and conspecified a trace of albumin. It was, however, free from blood, and had a specific gravity of 1015. The quantity ejected from the right ureter was greater than that ejected in the same time from the left. I have elsewhere (a) drawn special attention to this increase in the quantity of urine with diminished specific gravity in cases of renal calculus. It is a useful corroborative sign. At the operation, I found a large oval, brown, spiculated stone in the renal pelvis. I cannot understand how he had so little bleeding, as the surface of the stone, which was composed of oxalate of calcium, was rough as a file. The symptoms in this patient were comparatively mild when one considers the size and roughness of the stone. In another case, which I saw a few days later, the patient, a young lady, had more severe symptoms. She had vomiting during the attacks, and the pain, besides radiating towards the groin, extended down the outer side of the thigh. The attacks were also attended with fairly free hæmaturia. Here, again, the specific gravity of the urine on the affected was low-1005-as against 1015 on the sound side. In another case, the pain radiated down the outer side of the thigh to the great toe. In this case, again, the specific gravity was low on the affected sideunder 1005, as against 1015 on the sound side. In one or two of my cases, the pain was so severe as to cause symptoms of collapse. Several stated that they did not pass any urine during the attack, but that on its subsidence, a large quantity was passed. A youth upon whom I have just operated, had become a wreck from the frequency and severity of his attacks. His stone, a small uric acid calculus, was lodged in his ureter near his bladder, and was almost missed at the operation. I explored his kidney and its pelvis by a very free incision into the former, but no trace of a stone could be seen or felt. The ureter was palpated as far down as possible through a large lumbar wound, with a negative result. Finally, a long ureteral catheter was passed into the bladder from the kidney, and on withdrawing this the stone was dragged up into the pelvis of the kidney, and easily removed. In this case I noticed, during the operation, that the kidney was smaller than normal, and its behaviour to sulphindigodate of soda, previous to operation, was peculiar. We found that whereas in less than half-an-hour the sound kidney was excreting deep blue urine, the affected kidney did not commence to do so for at least a quarter-of-an-hour later. I have drawn your attention, so far, to fairly typical cases with well-marked symptoms, but it must not be supposed that all cases are so easily diagnosed. A year or two ago, a man was sent down to me from the medical wards, suffering from hæmaturia only. It was not clear from his symptoms whether the blood came from his bladder or from his kidneys. On cystoscopic examination, bloody urine

was seen to come from the left ureter, and on exploration, a minute, needle-shaped oxalate of calcium calculus was removed from the kidney. Cases like this are, however, rare. Generally, pain is associated with the hæmaturia. I have recently operated on a case of renal calculus in which there was neither pain nor hæmaturia. The patient stated that there had been some pain two years previously in the region of one ovary, but was confident that this was not connected with the present illness. She had symptoms suggestive of cystitis for a few weeks, but these passed off, leaving, as the only symptom, copious pyuria. At the operation, we found that she had a rough oxalate of calcium stone, completely filling the ureter at its junction with the pelvis of the kidney. A small channel on one surface of the calculus allowed the urine to trickle past the obstruction. There was. however, sufficient obstruction to produce a pyonephrosis, and there were also small abscesses in the remains of the cortex, so that I was obliged to remove the kidney. I had previously satisfied myself that the other kidney was in a condition to carry on the urinary secretion in a satisfactory way. From a study of these cases you will be prepared for the following classification of symptoms

-The pain which is produced by a renal calculus varies within wide limits. An aseptic calculus may lie quietly in the substance of the kidney without causing pain, or, at most, may give rise to an aching feeling which is often ascribed to rheumatism or lumbago. It is much less likely to be so free from symptoms if it is in the pelvis of the kidney. If the calculus is free to move, it soon makes itself felt by becoming engaged at the outlet of the pelvis. The most typical attacks of renal colic are produced by the passage of a stone along the ureter into the bladder. An intense and sometimes agonising pain is suddenly felt in the lumbar region. This extends along the course of the ureter and may involve the bladder, the inner or outer surface of the thigh and leg, even to the toes. At the same time it may extend to the testis of the affected side, or to the glans penis. It may even radiate to the abdominal viscera. agony may be so great that beads of cold sweat break out, and the pulse becomes small and rapid. Nausea and vomiting may occur, and the patient may lose consciousness. He may at this stage have frequent micturition, with straining to pass a few drops of bloody urine. This is called strangury. If sepsis be present he may in addition pass pus and mucus, which add to his distress by causing severe scalding of the urethra. If the stone blocks the ureter, the urine that is passed, being from the healthy ureter, may be free from pus or blood. Between the extremes of pain that I have mentioned, all degrees of distress may occur. The attack may suddenly cease by the calculus entering the bladder, or being displaced from the orifice of the ureter. While these attacks are fairly characteristic of renal calculus, they may be closely simulated by other conditions. Last summer I saw what appeared to be a typical case of renal calculus turn out to be an appendical abscess. Again, there are other conditions of the kidney which give rise to similar attacks, notably movable kidney, tubercle of the kidney, hydronephrosis, tumours, and acute congestion.

Hæmorrhage.—A very frequent symptom of renal calculus is hæmorrhage. It may, as Î have shown, be microscopical in amount, or it may be so profuse as to render the urine a bright red in colour, and it has even proved tatal. As a rule, however, the quantity is moderate, and colours the urine a dark red or brown. I must warn you, however that too much dependence must not be placed on the colour of the urine, as indicating its source of origin. I was recently asked to examine a patient with a view of ascertaining which kidney was affected. He was passing dark brown urine. On cystoscopic examination, we found that neither kidney was affected, but that a large carcinomatous ulcer of the bladder was the cause of the hæmorrhage. I have already pointed out that hæmorrhage may be the only symptom of stone present. It occasionally happens, however, that this symptom may be entirely absent, as in a case that I operated on a few months ago. This patient's urine was repeatedly examined by her husband, who was a medical man, but neither blood nor pus was found. I made the diagnosis chiefly from the pain and the specific gravity of the urine from the affected kidney. The X-rays, usually a most valuable means of diagnosis, failed in this case to discover the stone, which, though small, gave rise to very severe symptoms. The removal of the calculus was attended with complete relief of her symptoms.

Pyuria.—This symptom may be present in conjunction with blood and mucus. In the case to which I referred in the earlier part of this lecture, the only sign was pyuria. In most cases of stone, especially when the calculus is situated in the pelvis of the kidney,

there is pus in the urine.

Anuria.—Anuria may occur if by any chance both ureters are blocked by calculi, or if one ureter is obstructed and the other kidney is wanting. It is now, however, generally admitted that reflex anuria may occur. If one kidney be injured the secretion of both kidneys may cease, and fatal results may follow in this way from an operation for renal calculus. In a case on which I operated two years ago I was somewhat concerned to find that the patient passed no urine for twenty-four hours, and that the bladder was empty. I had previously ascertained that the other kidney was healthy, by the use of the ureteral catheter. Large injections of saline were given per rectum and the patient fortunately recovered.

Irritability of the Bladder.—Cases of bladder irritability are frequently brought to the surgeon to be treated for stone or other disease of the bladder, which, on cystoscopic examination, prove to be renal. In some cases stone in the kidney is found, but perhaps more frequently, some other affection, such as pyelitis, or tubercle of the kidney is discovered, so that it is not safe to diagnose cystitis or vesical stone from symptoms alone.

(To be concluded in our next.)

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Andrew Fullerton, M.D., F.R.C.S., Hon. Assistant Surgeon to the Royal Victoria Hospital, Belfast, and the Belfast Hospital for Sick Children. Subject: "Renal Calculus." Part 11.

#### ORIGINAL PAPERS.

# THE TREATMENT OF LABOUR IN CONTRACTED PELVIS. (a)

By Professor F. SCHAUTA, M.D.,

Honorary President of the Glasgow Obstetrical and Gynecological Society.

You have done me the honour of electing me Honorary President of the Gynæcological Society for 1907-1908. According to the rules of your Society, it is my duty to deliver before you an address during that time. Of the themes, the choice of which has been left to you, you have selected the subject "Labour in Contracted Pelvis." Thus, I appear before you to-night to speak in a country in which the science of contracted pelvis has been made classic.

Your great countryman, William Smellie, born in Lanark in 1697, must be considered as the real founder of the science of contracted pelvis. Obstetrics is indebted to him for the science of the mechanism of parturition, the first knowledge of the normal and pathological pelvis, and the measurement of the diagonal conjugate. He takes a firm stand against turning in contracted pelvis, as thereby the child is

(a) An Address delivered before the Glasgow Obstetrical and Gynmoological Society, April 7th, 1909,

too much endangered, and also against the application of foreeps above the brim. In order to restrain young practitioners from using the forceps in cases where the head is above the brim, thereby occasioning injuries to the mother, he recommends a short forceps, without pelvic curve, to be used only when the head had entered the pelvis. This view of discarding turning and the application of forceps above the brim is now again being revived by German obstetricians.

Regarding the rejection of the forceps, Smellie found powerful support in his countryman William Hunter. Indeed, Hunter went, in his views, beyond the standpoint of Smellie. The rejection of turning and forceps necessarily demanded the search for a substitute at a time when Cæsarean section was considered a deadly operation, and symphysiotomy, by reason of its great dangers, was then not even taken into account. Thus came into use the artificial induction of premature labour by Thomas Denmanm (1788) and craniotomy by William Osborn (1783). These eminent men had great confidence in the natural power of labour, a view strongly held to-day by all physicians.

Owing to Sir James Young Simpson, to whom we are indebted for the introduction of chloroform (1847), the long forceps and the cranioclast, turning in contracted pelvis was rehabilitated. This idea was based upon the assumption that the aftercoming head passes the pelvis more easily than the forthcoming head, contrary to the views of former physicians.

As the most distinguished exponent of the science

of contracted pelvis immediately after Smellie, George Stein the Younger, must be named. On the principles enumerated by these men, in conjunction with Michaelis and Litzman, our knowledge of labour in contracted pelvis has its foundation to the present day. The views held until recently regarding labour in contracted pelvis are in the main to be referred to the work of Smellie, Stein the Younger, Michaelis and Litzman. Their views are reproduced to-day in all text-books. Against these principles, firmly established for many decades and seemingly immutable, voices have been raised within recent times, maintaining that asepsis, which has made rapid strides, must be made use of more and more, in order to replace the old obstetrical for the so-called modern surgical operations, such as Cæsarean section and widening of the pelvis, and thus gradually paying a greater regard to the preservation of the life of the child, which, hitherto, was only taken into secondary consideration. This period seems to have begun more than twenty years ago with Kehrer and Sanger's improved method of uterine suture. But it was premature to substitute Cæsarean section, which was then and even now regarded as a most dangerous operation, for a method which allowed labour to take place through the natural passages. The reintroduction of widening of the pelvis, however, by the lateral incision has raised this question anew, which seems this time to be in a fair way of meeting with general acceptance. It appears to me, however, that even to-day the time has not arrived completely to abolish in contracted pelvis the so-called prophylactic opera-tions, such as artificial induction of premature labour, turning, craniotomy, and application of forceps above the brim, and to displace them by Cæsarean section and widening of the pelvis—operations which preserve the life of the child, although obstetricians of extreme views insist upon them at present. But all these questions have, no doubt, come within the province of practical discussion. And we are looking forward with joy to the time when it will be possible for us to discard all the interferences which jeopardise the life of the child, as we are living in an age which might be truly called the epoch of the child.

#### OPERATIONS IN CONTRACTED PELVIS.

The operations used in contracted pelvis are divided into three main groups. To the first group belong indicated measures, to the second prophylactic, and

to the third the so-called surgical operations. To the first-named groups belong all those measures which are indicated, not so much by contraction of the pelvis as by other anomalies of labour, anomalies which are mostly the result of contracted pelvis, but for the removal of which operative measures are absolutely necessary. These measures would be indicated apart from the complication of contracted pelvis. Among these operations must be named the application of forceps with the head in the pelvis, turning from a transverse presentation, the extraction by the breech, craniotomy on the dead child, and decapitation.

To the prophylactic operations belong artificial interruption of pregnancy (abortion or premature labour) and the so-called prophylactic version. The application of forceps above the brim is considered

by many to belong to this group.

To the so-called surgical operations belong all those in which the integrity of the mother's tissues is sacrificed in favour of the child, either by widening the pelvic space (symphysiotomy or hebotomy), or discarding the natural passages, by the formation of an artificial channel, whereby the child is extracted through the abdominal parietes and uterine wall (Cæsarean section).

Before we enter more fully upon the indications for the above-mentioned operations, we must discuss the question, which is very important, in relation to treatment, namely, how far we can count in cases of contracted pelvis upon spontaneous birth. This question has stood in the forefront of the discussion since Smellie's time, and has only been obscured from time to time by the overgrowth of operative methods which hindered the observation of the natural process of birth. With these operations, on the one hand the interests of the mother received too much consideration (abortion); on the other hand the interest of the child became more manifest (artificial induction of premature labour and prophylactic version)—operations which necessarily interfere with the observation of the natural course of labour.

Nevertheless, spontaneous birth affords by far the best solution of the many complicated problems of contracted pelvis. The objection might naturally be made that spontaneous birth is not always possible. This is, unfortunately, quite correct. But spontaneous birth is more frequently possible than it appears from our statistics. By premature inter-ference with its natural course, many cases of labour are directed into a wrong course and result in great injury to both mother and child.

At my clinique about 80 per cent. of the births with narrow pelvis actually occur spontaneously, in which only full term births are taken into account. is no doubt that if these principles, admitted in the present day, were universally and steadily observed, the number of spontaneous births in contracted

pelvis would steadily increase.

Now, the question forces itself upon us, does this expectant treatment not cause injury both to the mother and child-to the former on account of long duration of labour causing contusions to the soft parts, to the latter also from undue compression during birth? These consequences however do not occur These consequences, however, do not occur. Of all the possible methods of treatment of labour in contracted pelvis, the expectant treatment gives by far the best results for the mother as regards both mortality and morbidity. And I would mention here, that we consider the puerperium disturbed if the temperature has once risen to 38 deg. C. (100.4 deg. F.). Regarding the child we have also obtained the best results from spontaneous birth in preference to all other methods of treatment, with the exception of Cæsarean section.

We now come to the so-called indicated operations. Regarding results for mother and child obtained in cases of contracted pelvis by application of forceps when the head is in the pelvis, turning in cross presentations, craniotomy on the dead child, and de-capitation. One might be inclined to accept statistics without comment, as being those of patients treated

according to the prescribed and universally accepted rules, without there being any chance of deviation therefrom. Still, the question is justified, whether in all these cases a better result both for mother and child could not have been obtained by timely expert aid. In all the cases of turning the question is justified, whether another method of treatment could not have been adopted which would have been more advantageous to the child, thereby reducing the high mortality of the children. In a third of the cases where turning was resorted to, Cæsarean section or hebotomy carried out timeously might have saved these and probably other children. The same applies to breech presentation. In breech presentation, extraction need not always be adopted; a surgical operation may here, on account of the high degree of pelvic contraction, be quite as strongly indicated as it is in a cranial presentation. But these methods of dealing with such cases are partly of the past; nowadays an operation would certainly be considered.

Particularly must it be said regarding craniotomy on the dead child and decapitation that these operations have always been regarded as evidence of faulty midwifery. All these cases were admitted too late. Help was no longer possible for the child, and the mothers were, as the high mortality and morbidity show, frequently infected outside the institution. All these cases might have turned out differently if from the beginning a proper modern method of treat-ment had been adopted. I shall refer more fully to this point later on.

If we now turn to the more important group of prophylactic operations, the induction of artificial abortion must be put in the foreground. This operation was introduced by William Cooper in 1771, in order to avoid Cæsarean section where it was absolutely indicated. Cohnstein in 1874 could collect only ten cases, in all the literature, in which it was carried out in extreme contraction of the pelvis. To-day this operation has lost its justification on account of the safety of Cæsarean section. For this indication I have never operated.

On the contrary, the induction of artificial premature labour must be considered a justifiable and thoroughly established operation in contracted pelvis. It must be considered along with prophylactic turning, in the forefront, as a method in favour of the child, in order to avoid craniotomy at the normal term.

The indication given for induction of artificial premature labour is a conjugate between 7½ cm. and 82 cm. in generally contracted pelvis, and between 8 cm. and 9 cm. in flat pelvis. But when one can count on spontaneous birth in a conjugate of 8 cm. and even of 71 cm., the indication for induction of artificial premature labour falls to the ground on this score.

Nor is artificial induction of premature labour the easy method which some authors consider it to be. If only the operation in its narrowest sense be considered, such as the introduction of a bougie, artificial rupture of the membranes, or the plugging of the cervix, then certainly would the operation be a simple one. In the further progress of the case, however, other and more serious operations will have to be considered, which one cannot say would have been unavoidable had one waited for the normal termination of labour.

All cases of premature labour do not terminate spontaneously. One does not get a clear picture of the significance of artificial induction of premature labour if only the cases are counted in which spontaneous birth occurs. The high mortality of the children has rightly matured the question, whether one is justified in regarding the operation of artificial induction of premature labour as an operation carried out solely in the interest of the child. The result of births in the same woman, both mature and premature, were brought forward as an argument in favour of this operation. It was Dohrn who first put this view forward. But many of the births enumerated belonged to a former period of time and were not conducted under clinical treatment. Circumstances may have occurred which might have easily

operated unfavourably to the children.

The following observation appears more profitable:

—If we take from our total number of cases of contracted pelvis those which according to general opinion appeared particularly adapted for the artificial induction of premature labour, for example, multi-paræ with a conjugate from 7½ cm. to 8½ cm., and if we likewise eliminate artificial induction of pre-mature labour from the methods of treatment, we find that the very cases in which artificial induc-tion of premature labour has been discarded have had a more favourable result for both mother and child.

If, in opposition to some authorities, we are not inclined at the present moment to abolish the induction of premature labour from our list of operations in contracted pelvis, we would, at least, still further limit that operation to cases of multiparæ who are known to have given birth to large children with well-developed heads, children who are capable, in spite of their prematurity, of holding their own with weak and badly-developed, though mature, children. Such children, however, can only be regarded as premature in respect to the duration of their intrauterine life, and not in respect to the degree of their development. From a social point of view, it cannot be our task to put into this world premature and weakly children. In the struggle for existence, we require strong and well developed individuals.

Prophylactic turning as regards my clinique must be looked upon as a rare operation. If we would estimate the value of prophylactic turning in contracted pelvis, we must, as we have done in discussing premature labour, take into consideration the total results—first inclusive, then exclusive of prophylactic turning; more especially must we do this in that category of cases in which one expects from prophylactic turning the best result, namely, multiparæ with flat pelvis and a conjugate between 8½ and 9½ cm. The foregoing comparison, however, shows that the total result of prophylactic turning is unfavourable, and especially in those cases which are most suited for that operation, contrary to all reasonable expectation.

Very instructive, finally, is the comparison between spontaneous birth and prophylactic turning in respect of their results in the same categories of contracted pelvis, a comparison in which the circumstances most favourable for prophylactic turning have been assumed. In these cases, likewise the results of prophylactic turning are unfavourable. From these statements it is clear that in cases where there is a probability of spontaneous birth, prophylactic turning should be discarded.

The application of forceps above the brim, considered by some authors as belonging to the prophylactic measures, should not be included in this group, since it is used only in an advanced stage of labour with certain indications. Its use is justified as a last attempt to save the child, in cases where craniotomy on the living child might be considered neces-

If we consider the cases in which, in the absence of urgency regarding the mother, the operation has been performed solely in the interest of the child, we obtain an infantile mortality of 50 per cent. An operation which can by no means be regarded as free from risk to the mother, and which, when undertaken solely in the interest of the child, affords the saving only of every second child, should surely be replaced by another. Only when the operation is undertaken in cases of minor degree of contracted pelvis—between 8½ and 10 cm.—cases in which there is urgency on the part of the mother, can the application of forceps be tried, to be immediately replaced by craniotomy,

if any difficulty be met with.

In connection with the operation of prophylactic turning and the application of forceps above the brim, mention also should be made of craniotomy on the living child. This operation should, according to the view of some obstetricians, e.g., Pinard, be

entirely discarded. We cannot, however, altogether dispense with it to-day, as we regard it as an operation of necessity in cases where we find it impossible to carry out any of the alternative operations. In the future, Cæsarean section or hebotomy will take its place. To-day it is still indispensable in cases which reach expert aid too late, or in advanced stages of labour, often febrile from infection, where Cæsarean section or hebotomy is contraindicated, and in which, on account of the head being high above the brim, forceps cannot be applied, or on account of high degree of contraction of the pelvis, turning could not be performed and where the completion of labour is urgent.

It is, therefore, in the true sense of the word, an operation of necessity.

Craniotomy on the living child is one of the operations which will in the future be entirely eliminated from the list of obstetrical operations. We shall see at the end when and under what circumstances we may expect this golden age in obstetrics. In the meantime this operation should be limited as much as possible.

CÆSAREAN SECTION.

When we finally enter into the discussion of the so-called surgical operations in contracted pelvis, Cæsarean section, where absolutely indicated, might be put in the first place. The morbidity during the puerperal stage as shown by the mortality amounted to 17.2 per cent. These results should show a material improvement in the near future by the improved method in the protection of the wound, as it is customary in laparotomy at my clinique (rubber gloves, wound mask, and painting the abdom.nal walls with iodine).

The method of performing Cæsarean section at my clinique is by means of the usual longitudinal section of the uterus. The transverse section is only used in cases where there is considerable stretching of the lower segment of the uterus. As sutures for the uterine wound, silk is used in two layers.

The latest and most recent of obstetrical operations in contracted pelvis is that of hebosteotomy. We prefer it to symphysiotomy, on account of its more lasting results It is indicated in a contracted pelvis of 71 cm. to 81 cm. conjugata vera, when there is no infection, and the mother does not absolutely object to the operation.

For the operation of hebosteotomy the same stringent indications are not required as for Cæsarean section.

Patients who have previously been examined may undergo the operation of hebosteotomy, provided they show no signs of infection at the time of the operation, while for Cæsarean section absolute asepsis is a sine qua non. I would not like to go the length of some surgeons, who do not see in manifest infection a contra-indication to hebosteotomy. We operate in the manner of Döderlein by the subcutaneous method of incision, and await spontaneous birth, unless there is urgency to complete labour. All the cases, even those in which symphysiotomy had been previously performed (total, 23 cases) were successful. In 73.4 per cent. of the cases there was, however, some fever during the puerperium, due to the not infrequent during the puerperium, due to the not innequality injury to the soft parts. Only one of the children died (4.3 per cent. infantile mortality).

Accordingly it is essential that better results should in the near future be obtained in hebostcotomy with

respect to its high morbidity. This improvement will occur if we make it a principle to wait, particularly in primiparæ, for spontaneous birth. This method has been practised at my clinique only since the middle

of 1907,
Finally, if I am permitted to review the experience hitherto gained regarding the treatment of labour in contracted pelvis, and to draw conclusions therefrom, for the future, I might express myself as follows :-

The management of labour in contracted pelvis will shape itself in the future in the following simple manner, provided it is carried out from the very commencement in a skilful manner and in an institution under strict asepsis. In cases with a conjugate above 8 cm. there is a possibility of spontaneous birth, and therefore expectant treatment is to be adopted. In cases under 8 cm. Cæserean section is to be kept in view. In cases bordering on the above, i.e., a conjugate of 8½ cm. to 7½ cm., hebosteotomy is to be considered. This operation in a conjugate, of 8 cm. to 8½ cm., would be an alternative operation to spontaneous birth; in a conjugate of 7½ cm. to 8½ cm., an alternative to Cæsarean section. The choice would be determined by the size and hardness of head, the strength of labour pains, the voluntary efforts and general condition of the patient. This method of treatment should be looked upon in the future as typical.

All other methods hitherto used in the treatment of labour in contracted pelvis should be looked upon as non-typical. They are not to be considered as methods which were brought into use on account of the difficulty a contracted pelvis created in labour, but as entirely foreign to the subject, and they should not be capable of replacing the typical operations.

not be capable of replacing the typical operations. Craniotomy on the dead child, therefore, may be indicated in a conjugate under 9½ cm. The death of the child justifies in this case the adoption of a non-typical method of treatment. Craniotomy on the living child may become necessary if the mother is in a state of infection and refuses to undergo any of the typical operations. Artificial induction of premature labour may also have to be performed in cases in which the mother is suffering from illness and Cæsarean section or hebosteotomy at the normal term would be too dangerous, or where it is positively known that the children are abnormally large, or the mother absolutely refuses an operation. The application of forceps above the brim and prophylactic turning should, if possible, be entirely deleted from the list of methods of treatment in contracted pelvis.

The application of forceps above the brim might exceptionally be tried before craniotomy on the living child is resorted to, and it will probably be possible occasionally to save a child. Before craniotomy on the living child is undertaken, prophylactic turning may be justified in certain degrees of contraction in a simply flat pelvis, when Cæsarean section or hebosteotomy, on account of illness of the mother, is out of the question, and a trial with the forceps affords little hope of success on account of the high position and mobility of the head. The two last-mentioned operations (forceps above the brim and prophylactic turning) will find their indication in such atypical cases as a last attempt to save the life of the child before craniotomy is resorted to-forceps when the head is fixed, turning when it is movable. That the so-called indicated operations have at times to give place to surgical operations, as shown by our discussion, I have already previously mentioned.

In a conjugate under 61 cm., Cæsarean section is

In a conjugate under 6} cm., Cæsarean section is absolutely indicated, if the case be aseptic, with suture of the uterus; if septic, with total extirpation or supra-vaginal hysterectomy, even the most recent investigation into the management of labour in contracted pelvis will not alter this fact, and I therefore do not enter further into the question.

On the whole, our aim should be to leave labour in contracted pelvis as long as possible to the natural forces, and failing them, to perform only those operations which will most likely save both mother and child. All other operations should gradually be more and more limited. Until this golden age of the treatment of labour in contracted pelvis appears, there are certain conditions to be fulfilled.

The patient must reach the expert in an absolutely aseptic condition without any obstetrical interference of any kind having been made. The circumstances should be such that every kind of obstetrical operation can be immediately undertaken strictly aseptically; finally, our hands should not be tied from carrying out a certain operation by the refusal of the patient or her relatives.

All these conditions may most certainly be fulfilled in the case of patients with a high degree of pelvic contraction, especially if they have had difficulty with previous births, who seek admission to an institution from the very commencement of labour. In this way only can initial asepsis be assured and all the inopportune attempts on the part of the midwife and practitioner be eliminated, which so often lead to failure.

The natural forces will be more effective than when the patient, the relatives, and the midwife influence the doctor in attendance by demanding a rapid delivery of the case. If an operation becomes necessary, everything is at hand and no time is lost by taking the patient to an institution, where, as usual, after a lengthy consultation, a surgical operation is put aside in favour of another, which certainly could have been carried out at home, but which is only in the interest of the mother and to the detriment of the child. Thus I come to the last point, namely, the question of refusal on the part of the patient to undergo a certain operation.

There is no doubt that we must not perform an operation, whether obstetrical, gynæcological, or surgical, without the consent of the patient. Assuming this general consent, the choice of the operation should be left in all its details to the operator. In gynæcological operations this has been customary for a long time. Why, then, should the patient have the right to refuse a particular operation which the operator in the case, after mature deliberation, considers to be the best for both mother and child. It is the request for consent to perform a specially named operation which suggests to the patient that this operation is particularly dangerous. Still we perform other dangerous operations without the special consent of the patient. Application of forceps above the brim and prophylactic turning have also their dangers. In these operations injuries also occur, such as lacerations and wounds, to which the straight aseptic incision is preferable. Still nobody asks the patient if she would allow any of these operations or the destruction of her child by craniotomy. Let us, however, frankly admit that, with regard to surgical operations in contracted pelvis, we still stick to the traditions of the time when Cæsarean section was a deadly operation, but it is high time we should break with these traditions.

It is certainly quite true that Cæsarean section, and to some extent, also, hebosteotomy, are even to-day more dangerous than all the other, obstetrical operations in contracted pelvis. If, however, a patient, in whom such an operation may become necessary, would from the very beginning get into a public or private institution, where everything can be carried out strictly aseptically, to await her confinement there, then all these influences which affect Cæsarean section so adversely would disappear. Nowadays patients seek admission to an institution at all times, night and day, often in a badly neglected condition. In the space of half an hour everything is to be made ready for Cæsarean section, the abdominal walls are to be disinfected, an anæsthetic to be administered, although the patient may have shortly before partaken of food and drink. The sur-geons of the institution, who are not prepared for laparotomy in the late hours of the evening or night, must hurriedly disinfect themselves, which is very often inadequately done, as their hands in the course of the preceding day's work have become infected. That in such circumstances infections and pneumonias occur our statistics show, as do those of other cliniques. Upon these statistics, however, I base my opinion regarding the danger of Cæsarean section. statistics must be collected anew, with the elimination of all the incidents I mentioned above. All the dangers of this operation will then be reduced to a minimum, and everyone of us will be able to undertake with a clear conscience every kind of obstetrical operation. Until then, however, by a careful selection of cases, the percentage of danger should be reduced to the lowest minimum.

I regard as intolerable and a hindrance to all future progress the constantly recurring statement that the country practitioner cannot and should not perform Cæsarean section or hebosteotomy, and should, therefore, as formerly perform only the prophylactic opera-tions and high forceps operation. For this reason all obstetrical schools lay great stress to this day upon the teaching of these operations. If the general practitioner, however, would get accustomed to recognise timeously high degrees of contracted pelvis, i.e., before the onset of labour, and to assign all these cases, also timeously, to obstetrical institutions, then might progress also be made in the country and in

private practice.

Physicians must be taught to think and to make their influence felt upon midwives and on the public generally, and not to stand, as hitherto, inactively awaiting events, and ultimately performing an oldfashioned operation, most frequently forceps and craniotomy, whereby the child is sacrificed. Innumerable cases in my own experience have proved to me that it is possible to instruct physicians in the way I have mentioned, and not permit them to adopt

a fatalist attitude towards events.

The level of education of midwives should be raised

pari passu with that of the physicians.

We gain nothing by the statement that the physician is mostly called too late. We must strive to change all this, and it will be changed if we try our utmost in that direction. Obstetrical schools in this respect should take the lead, and not, as often happens, completely resign themselves to fate. General practitioners must endeavour to bring the level of their knowledge to that of clinical specialists, and should not seem, as frequently appears to-day, as though they were adopting the opposite course.

I am at the end of my long address. It is difficult however, to shorten such an important chapter of Almost all obstetrical operations must be mentioned and discussed in their past and future bearing upon our subject. If, perhaps, it appears that my proposals go too far, still the higher the aim the more we will attain. Our fate, however, will be to remain somewhat below the highest standard, for we are human and have to deal with humanity, whose human arrangements and prejudices we have to combat. If I have succeeded in gaining the co-operation of the physicians of Scotland, who have always stood in the forefront of obstetrical science, in reaching this high goal, I would feel that my time and labour have

#### A CASE OF PRIMARY CARCINOMA OF THE VAGINA. (a)

been amply rewarded.

By GORDON W. FITZGERALD, M.D. Ed., M.CH.,

Examiner in Midwifery and Gynsecology, Durham University College of Medicine, Newcastle-upon-Tyne; Lecturer in Midwifery, Manchester Union Hospital.

THE rarity of malignant disease having for its primary focus the vagina is my chief reason for bringing this case before the Society. Though cases of this kind are usually shown or described at one of the medical societies, or reported in one of the medical periodicals, the search for recorded cases is a most tedious undertaking, and the sum of one's investigations of the literature is only a few score of cases.

The patient, æt. 26, had at the time of my seeing her been married eight months, and had never been pregnant. I saw her on December 2nd, 1908, and the history she gave was that for eighteen months she had been troubled with an offensive vaginal discharge which had latterly been blood-stained. On November 26th her expected menstruation came on, and the amount was so much in excess of the usual that she consulted Dr. Gregory, with whom I saw her. She had at

no time experienced any pelvic pain. She thought that she had grown somewhat thinner, but was a plump young woman and looked in the best of health.

On vaginal examination the cervix could be felt in its normal position and of normal consistency, and the uterus not enlarged, normally situated, and fairly movable. The left fornix could be felt to be the site of an irregularly punched-out depression, which on inspection was found to be an ulcerating area about the size of a two-shilling piece, of more or less circular shape, with in-It was durated, clean-cut and everted edges. about a quarter of an inch in depth and its base showed raised spots of a bright red and angry appearance, with here and there little sloughing areas. The odour of the discharge was rather that of a sloughing polypus than that of malignant disease.

The vicer came very close to the uterus, but a small band of healthy and non-indurated tissue separated it from the cervix, while the latter-the cervix—appeared to be healthy. No enlarged

glands were found in either groin.

On December 5th I removed a portion from the edge near the cervix and another from the edge bordering on the left vaginal wall. These specimens Professor Delépine kindly examined microscopically for me, and declared them to be typical specimens of squamous-celled carcinoma-and he is of opinion that the condition is a primary

vaginal growth.

The operation—which was done on December 8th -I started with the hope that it would be possible to save the uterus, and, with this object in view, divided the anterior, left lateral and posterior walls of the vagina well clear of the growth and the surrounding induration, and completed the incision by cutting into the left side of the cervix. The vaginal walls were then dissected up and an endeavour made to free the ulcer from its base. In this I was not readily successful, as it was very closely adherent to the bladder and the uterus. This very close relationship with the uterus decided me to remove that organ, for it seemed highly likely that, though no evidence of involvement of the uterus had as yet been discovered, the pro-bability of its being already the seat of malignant disease was very great, and hysterectomy, therefore, seemed almost imperative. The operation was completed by the abdomen. This route gave me much greater freedom in dealing with the adhesion to the bladder, and enabled me to search the pelvis for infected glands in a manner which would have been impossible had the operation been completed by the vagina.

Despite this extra freedom, it was only with a great deal of difficulty that the bladder was liberated. Having removed the uterus, I cleared out as carefully as possible the left appendages and the cellular tissue on the left side of the pelvis, making at the same time a search for infected glands. No enlarged glands were found at all.

Before closing the abdomen the bladder was examined and a catheter passed; the urine drawn off was clear and no evidence of wounding was found. I mention this for the reason that on the day after the operation, and again the day after that, she passed urine which contained quite a large amount of blood. On the fourth or fifth day of her convalescence the blood disappeared and was not again seen. The hæmaturia, I take it, was evidence of the fact that though the bladder showed no evidence of wounding, there must have been some-she never had passed blood beforeand it naturally raises the question as to whether

<sup>(</sup>a) Paper read before the North of England Obstetrical and ynmeological Society, at Liverpool, Feb. 19th, 1909.

the bladder was not to some extent already involved. She made a very good convalescence, and went home in three weeks.

It is interesting to look to the recorded experiences of others in an endeavour to form some idea as to the frequency with which carcinoma is found as a primary condition in the vagina, its disposition, and the results of operation.

Both sarcoma and carcinoma are found affecting primarily the vagina, and, while the former is admitted by all authorities to be of extreme rarity, carcinoma is regarded as being of sufficient rarity to render the records of a case always of interest

and value.

Its frequency is varyingly estimated. Williams (London Hospital) says it occurs in 0.43 per cent. of all cases. Hart and Barbour collected fourteen cases out of a total of 8,287 cases of cancer of the female generative organs-a percentage, roughly, of 0.17; Christian Fenger collected fifty-seven cases out of all the literature on the subject, while, at a somewhat earlier date, Kustner and Preuschen together collected thirty-three. These are included in Fenger's series. On looking through the "Transactions," I find that only one case has been brought before this Society-the specimen was shown by Dr. Gemmel at the November meeting last year; in the "Transactions of the London Obstetrical Society" I find one case reported by Dr. F. J. McCann, while in the "Transactions of the Gynæcological Society," and more recently in the state of the Parel Society of Medicine I find those of the Royal Society of Medicine, I find none, and, except as a reference to the proceedings of one or other society, there is no record of such a case to be found in the Journal of Obstetrics and Gynæcology of the British Empire.

From this scarcity of cases, and the small percentage quoted by one or two, one naturally concludes that the condition is an uncommon one, but I think we must accept as highly probable the fact that a great many more of these cases occur than one can find records of; they are either not recognised as such or are not recorded. Dr. James Oliver has published the records of three cases, the youngest being the same age as my own case—26. In this patient there had been pain for eight months, and profuse watery and offensive discharge for only four months, following on twelve months amennorrhoea after confinement. The whole of

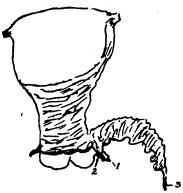

the vagina was in a cancerous state.

In his two other cases, the ages of whom were 62 and 53 respectively, they were very far advanced also, and there was marked involvement of the inguinal glands; no mention is made of this in the first case; pain was absent in both of these cases. In two out of three there is recorded an involvement of the inguinal glands, but in view of the fact that the condition was so far advanced, this is not surprising. Indeed, though the majority seem to regard the condition as less prone to lead to involvement of the glands in the groin than is the case with uterine cancer, the stage of the disease and the position in the vagina must be the most potent factor in deciding this, in virtue of the distribution of the lymphatics in the vagina. There appears to be a generally-entertained opinion that carcinoma occurs earlier as a primary growth in the vagina than it does in the uterus. According to Fenger it may roughly be said to occur ten years sooner in the vagina.

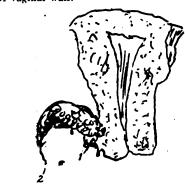

Howard Kelly and Noble, in the brief reference which they give to this important condition, say that it usually occurs after the fortieth year, but that it has been found in children. I have been unable to find any record of the condition occurring

in children; indeed, the youngest patient is one who was under the care of Mr. C. Arthur Wood in the Nagasaki Hospital, Japan; her age was 22.

Site.—With but few exceptions the posterior wall of the vagina is the site of the growth. In twenty-five out of twenty-nine cases Fenger found it so situated, two being on the anterior and two on the lateral walls. Butlin, who has given attention to this subject in his "Operative Surgery of Malignant Disease," is also strongly of opinion that the posterior wall is the most usual site. This case I am now recording is the first case of the kind I am now recording is the first case of the kind I show very clearly the position of the growth to be lateral. It is seen still occupying its original

Anterior surface of uterus with ulcer attached. 1. Edge of ulcer. 2. Apparently healthy tissue. 3. Tag of vaginal wall.

Anterior half of longitudinally bisected uterus. 1. Growth encroaching on cervix. 2. Tag of vaginal wall.

position in relation to the uterus. Its very close attachment to the cervix, which already has become involved to some extent, and the numerous and dense adhesions to the bladder, suggest that the next and by no means remote stage would have been the more or less extensive involvement of these. As a rule the bladder, rectum and uterus appear to be attacked quite early in the course of the disease; in some of the reported cases the distress experienced in consequence of this appears to have been the primary reason of advice having been sought. In my own case, however, the offensive discharge had persisted for eighteen months, and it is therefore hardly an example of the condition spreading very rapidly, vet the pathologist is of the opinion that it shows indications of rapid growth. The condition is described as assuming one of two forms, either the ulcerating-of which my own case is an example—or a diffuse infiltra-tion of the walls. When primary in the vagina

the carcinoma is practically always of the squamous-celled-the epitheliomatous variety. The infiltration may go on to the stage of practically complete occlusion of the canal, one of Dr. Oliver's cases being an example of this; and it is distinctly

the more rapidly spreading form.

We so seldom see these cases at a sufficiently early stage that, though one recognises that operation should be done very early in the history of the case to hold out any hope of cure, the results so far got from operation are by no means as good as one would hope for them to be; 80 per cent. to 90 per cent. of cases operated upon have recurrence of the disease. Patients will frequently tell us that the condition has persisted for only two or three months, but I am sure I am not wrong in saying that it is most exceptional for us to see a patient with malignant disease in so early There can be no doubt, too, that a patient will frequently be allowed to go on with a malignant growth until she arrives at almost the stage of its being inoperable in consequence of no vaginal examination having been made in the first instance-for this the patient is often quite as much, if not more, to blame than the medical attendant.

Recurrence seems in most cases to have been very rapid. No doubt the absence of glandular involvement should lead one to be more hopeful.
Of all the operations for the removal of the growth Olshausen has suggested the most radical.

I saw my patient on January 26th. looking very well and declared that she had gained weight; the local conditions, too, I found on examination to be quite satisfactory.

#### A NOTE ON OXALATE OF CERIUM.

By J. C. McWALTER, M.A., F.F.P. and S. Glas., M.D. Brux.,

Examiner in Materia Medica at Apothecaries' Hall, Dublin.

OPERATIONS for gastric ulcer now occupy much of the attention of surgeons, and so many of them harangue the poor practitioner on the necessity for early diagnosis and immediate operative procedure that one is almost afraid to suggest the futility of most of these undertakings. At least it is the experience of many physicians that some 90 per cent. of those cases clinically diagnosed as gastric ulcer get almost well with the bismuth and morphine treatment—whilst probably 50 per cent. of cases treated by operation are worse after a couple of years.

In connection with the medical treatment of ulcer of the stomach, hyperchlorhydria, hunger pain or allied conditions, I wish to draw the more earnest attention of the profession to an old but neglected remedy-oxalate of cerium. All the world knows that in the vomiting of pregnancy it is almost a specific—thanks to the enthusiastic praise of Simpson-but in inflammatory or erosive conditions of the intestinal mucous membrane it appears to be not only of considerable service, but in many respects better than bismuth.

Since radium became the rage in scientific circles, much attention has been devoted to the rarer metals. Cerium is found as a by-product in the preparation of thorium from monazite, and as found in commerce, consists of cerium, lanthanam and didymium oxalates.

Cerium nitrate is largely used in the preparation of incandescent gas mantles, and is a salt soluble in water, and convenient to administer in the effervescing form, but clinically, the better preparation is probably the insoluble oxalate, because cerium is not absorbed, but acts locally and

mechanically like bismuth.

The oxalate of cerium depends for its therapeutic properties not only on the base, but in the acid radicle. To the modern mind oxalic acid is nothing but an irritant poison; but Neligan long ago pointed out that minute doses of oxalic acid-I to 3 grains—were invaluable in inflammatory conditions of the gastric mucous membrane. Its action is on the nervous element of gastric disorders, and modern writers have shown that the pain which accompanies gastric erosion or ulceration is due rather to the spasm which succeeds the ingestion of food than to the local effects of the gastric secretion on the raw surface of the membrane.

Oxalate of cerium is best given, not in pill, but in powder or mixture. It is best of all combined with bismuth—say two grains of cerium to ten of bismuth. It appears to do excellently in the ordinary bismuth mixture of the hospitals as an addition of some thirty grains to each dozen doses. The constipation which usually accompanies the taking of bismuth soon lessens by its use, and the lack of desire for food, which is another concomitant, becomes almost absent.

Some may sneer at such insistence on the properties of a drug whose action is largely mechanical, but gastric ulcer is one of the commonest diseases, and one of the most painful and fatal. Its treatment is practically either by operation, rest, or bismuth and morphine. there be a further remedy in oxalate of cerium it is well to spread its fame.

#### OPERATING THEATRES.

GUY'S HOSPITAL.

CASE OF RUPTURED URETER DUE TO TRIVIAL INJURY.—MR. R. P. ROWLANDS operated on a youth, set. 18, who had been admitted complaining of great pain in the left side of the abdomen. Two days before admission, whilst walking along the pavement with his left hand in his pocket, he fell on his left elbow, his hand being driven against the lower part of the abdomen, and causing an agonising pain shooting up to the left loin. Gradually a swelling appeared on the left side of the abdomen, and the patient was sick several times. On admission the temperature was 102°, and pulse 110 to 120. The lower part of the

abdomen moved but little on respiration; the left iliac fossa was fulle: and less resonant than natural, and very tender. If the local signs had been on the right side, his general and local condition would have agreed well with an attack of appendicitis. There was some tenderness and fulness in the left loin pos-The bowels were constipated, the urine and teriorly. The bowels were constipated, the urine and the act of micturition were normal. The viscera were not transposed.

The abdomen was explored through the lower part of the left rectus. Some clear fluid escaped, but there was no septic peritonitis, and the appendix was normal. The retro-peritoneal tissue and the left mesocolon were very &dematous, with a greenish translucent appearance. The swelling extended up to the left kidney, which appeared to be normal in size and consistency. The abdomen was closed, and the patient was turned over on to his right side, and the left kidney was explored. On opening the peri-renal tissue a good deal of slightly blood-stained fluid escaped. With some difficulty the kidney and the upper part of the ureter were isolated, and a clot of blood was seen plugging a large rent at the junction of the ureter and the renal pelvis inferiorly. The laceration extended nearly all the way round, a small part still remaining undivided at the upper and inner part of the tube. The clot had obstructed the lumen of the the tube. The clot had obstructed the lumen of the ureter. The rent was sutured with fine catgut in such ureter the lumen of the ureter ureter. The rent was sutured with fine catgut in such a way that no narrowing of the lumen of the ureter resulted. This was not easy because of the depth of the wound, and the great amount of cedema of the surrounding tissues which kept flapping into the way The loin was drained by means of a large cigarette drain, and the wound closed all round.

Mr. Rowlands said that, although a ruptured ureter was suspected, the accident seemed to have been too trivial to produce such a severe injury, but, in the light of after events it seemed clear that the left hand impacted upon the ureter and pressed it inwards upon the pelvic brim, thus tearing the tube from the more or less fixed kidney. The situation of the rent at the lower and outer part of the junction of the renal pelvis and the ureter confirmed this view. The absence of hæmaturia and of all urinary symptoms, and the signs suggestive of local peritonitis in the left iliac fossa, added difficulties to the diagnosis and rendered an abdominal exploration necessary. A cystoscopic examination might have made this unnecessary, but no harm was done and but little delay caused by the preliminary exploration, which at ouce settled the diagnosis. The prospect of complete recovery of the kidney after suture of such an extensive laceration seemed poor at first, Mr. Rowlands thought, but the difficulties would probably yield to the careful plastic

operation he had just performed. The absence of hæmaturia, he pointed out, was not uncommon in case of complete or nearly complete rupture of the ureter, and the accident is often unexpected until a swelling appears in the loin.

At first nearly all the urine escaped through the

loin, and it was feared that another operation would become necessary; but after about ten days a little pus appeared in the urine, and the amount passed per methram gradually increased. The sinus in the loin closed at the end of four weeks. The patient was seen quite well two and a-half months after the operation, and he has returned to his work, the urine being

normal and the youth having gained considerably in weight.

#### TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

MEETING HELD FRIDAY, MARCH 26TH, 1909.

Dr. EDMUND CAUTLEY in the Chair.

EXHIBITION OF CASES AND SPECIMENS. MR. MACLEOD YEARSLEY showed a case of a peculiar form of word-deafness successfully treated by the oral

method. The child could not appreciate heard speech, which she merely repeated aloud, but when she was which she increased repeated about the word-able to see the speaker such seen speech (lip reading) was immediately answered rationally. The wordwas immediately answered rationally. The word-deafness apparently prevented the higner centre being effective, but she has now learnt to understand by lip reading. After practice, with great effort heard phrases are now understood and answered without the motor response of repeating the question. Mr. Yearsley thought that it was difficult to explain the case on any hypothesis other than that of weakness of the auditory centres.

Dr. H. C. MANN exhibited a specimen of a tumour (7 in. long by 4½ in. broad), of the left suprarenal obtained from the body of a child, æt. 2. The kidney lay at its lower pole. The growth extended through the diaphragm, invading the pericardium and left lung. The left pleura contained nearly a pint of blood-stained fluid, and showed small secondary growths. The cervical glands were sarcomatous. Secondary deposits were also found in the orbital plates, in the right parietal bone, and in the sternum. The child came to hospital with a history of 6 weeks' weakness and anæmia. A leucocyte count showed 15,000 white cells; hæmoglobin and red cells, 60 per cent. The tumour, which during life was apparently splenic, enlarged rapidly under observation. It moved well with respiration. Death occurred two months later. The tumour was a round-celled sarcoma.

Dr. EDMUND CAUTLEY showed (1) the brain from a case of cerebral diplegic spasticity, which had been shown to the section on February 20th, 1909. The whole of the frontal and parietal regions was converted into a bilateral cystic form, bounded mesially by a wall containing a moderate amount of brain substance. According to the history, the child had been healthy till the age of 7 weeks, and then had an illness which could be accounted for as encephalitis or menin-The post-mortem appearance made it more probable that the condition was congenital, dependent on developmental error in the prosencephalon. (2) A specimen of congenital heart disease, showing transposition of the aorta and pulmonary artery. The right ventricle was the larger, and gave off a normal aorta from which the great vessels arose by a common origin. The left ventricle gave off the pulmonary artery, which was stenosed on account of two of its valves being adherent. There was a small opening in the interventricular septum, and the foramen ovale was patent. The ductus arteriosus was normal. The child lived till. 11 months, showing moderate cyanosis and clubbing. The heart was enlarged to the right of the sternum. There was a systolic pulmonary murmur, and a systolic

murmur heard at the apex and behind.

Dr. LANGMEAD said that there was a specimen in. the museum of Great Ormond Street Hospital which closely resembled Dr. Cautley's first case. It showed some narrowing of the small cerebral vessels.

Dr. G. CARPENTER said he had neither seen nor read of a case like Dr. Cautley's, but had seen a locular cystic condition, which Dr. Ernest Jones reported was, in his opinion, syphilitic. During life the child had been spastic, with head retraction, and showed atrophic patches in its choroid.

Dr. JEX-BLAKE showed a female child, æt. 7, with congenital heart disease. She had a good colour, and weighed 28 lb. Over the pulmonary area a continuous murmur could be heard, loudest during systole. It could also be heard over the whole chest, back and

Dr. Whipham thought there were one or two small glands to be felt in the neck. If the murmur was not due to glands, he would agree that it was caused by a patent ductus arteriosus.

Dr. G. LE B. TURTLE asked whether the murmur varied in intensity from time to time. when it was due to enlarged glands.

The CHAIRMAN thought that it was a purely systolic murmur, and was inclined to ascribe it to some pulmonary stenosis and patency of the inter-ventricular septum, than some other defect, because there was so much hypertrophy. The child had not grown well, which he thought meant a bad prognosis.

Dr. JEX-BLAKE replied that the murmur had not

been noticed to grow louder or softer at different times. Dr. G. CARPENTER exhibited a case of congenital malformation of the heart, showing a patent ductus arteriosus, with bicuspid aortic valves. The child died arteriosus, with bicuspid aortic valves. The child died at the age of three months. During life there was a systolic murmur, best heard over the third left space just inside the nipple line conducted towards the left clavicle. The left side of the heart was the larger. The right ventricle was dwarfed. The foramen ovale was closed.

Dr. WHIPHAM gave a pathological report upon 'he specimen of congenital cystic disease of the kidneys, shown at the Section on January 22nd, 1909. The sections showed small cysts, with a great increase of connective tissue. The tubules were mostly dilated, but many were contracted. Glomeruli were somewhat contracted, but Bowman's capsules were dilated. The arteries were thickened. The pancreas showed some fibrosis and thickening of its vessels. The bile-ducts of the liver were dilated and convoluted. The spleen showed an excess of connective tissue.

Dr. PARKES WEBER thought that the spaces in the portal fissures might be blind spaces, and not dilated bile vessels. In that case the liver was an example of

cystic liver.

Dr. T. R. WHIPHAM showed transparencies and photographs of a case of bullous purpura following impetigo in a boy, æt. 4. There was no history of hæmophilia or of syphilis in the patient or his family. The fluid from the bullæ contained degenerated bloodcorpuscles, but no growth of organisms could be obtained by cultivation. From the impetigo lesions a mixed growth of staphylococcus albus, citreus and streptococcus was obtained. The patient was given boracic baths, and the bullæ either were punctured or burst spontaneously, leaving deep, sloughing ulcers. Under treatment with hydrogen peroxide, chinosol baths, and balsam of Peru dressings, the ulcers cleaned, and the condition was now cured.

Dr. G. Pernet referred to a paper he had read on bullous impetigo contagiosus in children who had pediculosis. The purpuric condition was more unusual. He thought, in the present case, that the purpura was

of streptococcal origin.

Dr. Whipham showed a case of transposition of the viscera in a girl, æt. 8. There was a mitral systolic murmur at the heart's apex. The child had had chorea twice.

The CHAIRMAN thought that such cases were not so uncommon as one was led to believe in books. He believed that prognosis of life was just as good as if the heart were not transposed.

Dr. F. J. POYNTON and Dr. LANGMEAD thought that

if the heart was on the right side of the body, there

was greater liability to endocarditis.

Dr. PARKES WEBER asked whether proposers for life assurance should be rated up if the viscera were transposed?

Dr. Whipham thought not.
Mr. O. L. Addison showed (1) a case of ankylosis of both hip-joints ascribed to scarlet fever, and (2) a case of syphilitic osteoperiostitis.

The CHARRMAN asked what treatment had been adopted in Case 2, and Dr. E. I. SPRIGGS asked whether the tissues or fluids had been examined for the spirochæte.

Mr. Addison replied that after operation the general conditions had improved under mercury and iodide. There was still a sinus over the tibia. Spirochætes had not been looked for.

Dr. F. J. POYNTON showed a case of congenital symmetrical swellings on both heels in a girl. His view was that they were lipomata.

Dr. Pernet agreed.

Dr. CARPENTER showed a microscopical specimen of the liver from a case of icterus neonatorum in a child, aged 19 days. She beceme jaundiced on the second day. The navel was healthy; the stools were green. There was a systolic murmur over the left pulmonary area and in the left axilla. Post-mortem, the liver was not enlarged, but its section was a deep mahogany colour, with large visible veins. As far as the bile cucts could be traced, they were empty, and not obstructed. Microscopically, the liver walls were crammed with bile granules of an olive-grey colour. The fine bile capillaries were filled with inspissated bile in irregular-shaped masses, and showed a moniliform outline.

Dr. E. I. Spriggs said it was not necessary for there to be gross blockage for the production of obstructive jaundice, not only in the condition of toluylenediamine poisoning, but in acute yellow atrophy and phosphorus poisoning. It was probable that the jaundice occurred because of the catarrh of the small bile ducts. That might also account for liver cells containing particles of pigment.

Dr. Poynton referred to two cases which he brought before the section two years ago, in which the children got well. He thought that in cases of prolonged jauridice it was a mistake to vaccinate the child. He did not think that such cases were common.

Dr. PARKES WEBER referred to cases in which several children of the same parents had had jaundice, some

of them having died.
Dr. PORTER PARKINSON read a paper on three cases of

HENOCH'S PURPURA.

Case I was a boy, set. 8, who suffered from pain in the legs and abdomen, and a purpuric rash over most of the body and limbs. The spleen could be felt. The urine contained albumin, and occasionally a trace of blood and casts. The abdomen was tender in the epigastric and right iliac regions, and there was occasional vomiting. The child was treated with two injections of horse serum without any improvement, but recovered, and was discharged with the urine still

Case 2 was a boy, æt. 6, suffering from abdominal rain and vomiting. There were purpuric spots all over the extensor aspects of the limbs. The abdomen was not tender. The urine contained albumin and occasionally blood. In hospital he was suddenly attacked with abdominal pain, and the abdomen became tender in the left lumbar region. The pain continued on and off for nearly two months, occurring in crises every two days. Blood was found in the stools during most of this time. Later the face became puffy, especially the lips and eyelids, but the child began to slowly improve. The treatment was at first calcium chloride, and later three injections of horse serum. Two fresh groups of purpuric spots appeared while the child was taking calcium.

The third case, under the care of Dr. Charles Bolton, was a boy, æt. 6, who came into hospital with severe pain, and passing blood in the stools, with a measly non-purpuric rash and coryza. The next day he vomited and passed blood and mucus by the rectum. The abdomen becoming distended, it was thought that intussusception might be present, and the abdomen was opened, but none found. There were flecks of lymph in the peritoneum, with some evidence of general peritonitis. He died next day. At the necropsy there was general peritonitis, and on the small intestire were about 13 hæmorrhagic extravasations about the size of peas, and projecting on both outer and inner surfaces of the intestine. About a foot from the iliac valve there was a collection of much larger hæmorrhage. The small intestine was distended with gas, and the large intestine as far as the splenic flexure, where for about 6 in. it was quite dark from diffuse hæmorrhage, thickened, and looked almost gangrerous. The diagnosis lay between measles and Henoch's purpura, the suspicion of intussusception not being verified. Dr. Parkinson thought it was a case of purpura, but the absence of blood and albumin in the urine was unusual. The case supported a suggestion of Mr. Hugh Lett, made in the "Reports of the Society for the Study of Disease in Children" that it is advisable not to operate for intussusception in a case of Henoch's purpura unless an abdominal tumour can be felt.

Mr. Hugh Lett said the presence or absence of intussusception in Henoch's purpura was very important. He had reported a case in which intussusception had developed during the illness, and was reduced by operation. Seventeen days later another intussusception occurred, and the child died. thought that the crucial feature to be relied upon was

the presence of a sausage-shaped tumour, and that there should be no operation where a tumour was not felt. He had operated upon 28 cases of intussusception, in all of which he felt a tumour either from the abdomen or per rectum. In two or three of them he could not feel it without an anæsthetic. Surgical operation in Henoch's purpura was a very serious matter, and in some cases the patient had died of hæmorrhage from the wound. If he saw another case of undoubted intussusception with purpura, he would be inclined to try injection before operation.

Dr. LANGMEAD said that a tumour might be present simulating intussusception, but due to extravasation of blood, and Dr. E. I. SPRIGGS referred to another case showing this condition.

The CHAIRMAN thought the term, "Henoch's purpura," should be dropped, as the disease was simply purpura hæmorrhagica with abdominal symptoms, and Dr. PERNET agreed.

Mr. Lockhart Mummery showed a case of hyperplastic tuberculosis of the rectum in a boy, æt. 10. There was no pain or straining, but the bowels were loose, being opened as many as 20 times a day. There was no vomiting or wasting, and the appetite was good. Large masses could be felt projecting in the rectum from all sides, irregular in surface and shape. With the sigmoidoscope several ulcers about a third of an inch in diameter were seen, and had the appearance of tuberculous ulcerations. The whole of the mucosa of the rectum was red and swollen. The ulceration quickly cleared up under the influence of daily irrigation with weak antiseptics.

Dr. G. CARPENTER showed a case of scurvy in a boy, aged I year and 4 months. He had been reared on cow's milk and barley water for the first 3 months, and afterwards he had been given bread and milk, etc. He was admitted to hospital with a history of two falls, and was found to have a bruise over the right eye and a hæmatoma of the scalp with a cranial fracture. After 12 days he was discharged as cured, and continued in good health for six weeks, when he was re-admitted with a swelling in the left arm without any history of injury. The swelling extended from the shoulder on to the forearm. There were also marks of old hæmorrhages on the backs of both feet. The skiagram showed no fracture. He had improved very much on a suitable diet.

#### ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

MEETING HELD FRIDAY, APRIL 2ND, 1909.

The President, E. H. TWEEDY, in the Chair.

#### EXHIBITS.

Dr. Purefoy showed a small uterus removed for recurrent hæmorrhage from a patient, æt. 50, the mother of some children. She had been curetted in the first instance, and some thickened membrane had been removed. Some improvement was made, but the hæmorrhage recurred. Atmocausis was applied, but after another violent recurrence the uterus was removed. The specimen showed enormously thickened uterine walls, and the position of the endometrium indicated in section by a thin line showing almost complete absence of endometrium.

Dr. HOLMES recalled a case of Sir Arthur Macan's in which the hæmorrhage recurred after atmocausis and hysterectomy was performed. The vessels of the uterus were distinctly atheromatous, and it was doubtful if atmocausis would cure in such a condition.

Dr. JELLETT expressed great doubt as to the value of atmocausis in cases in which there was no endometrium. The hæmorrhages apparently came from blood vessels more or less diseased, and the superficial effect of atmocausis could not be permanent. He did not see how a second application of atmocausis would produce more than a temporary result as in the first application. He thought there was nothing left in such cases but hysterectomy.

Sir William Smyly said he saw a great theoretical difference between atmocausis and curetting. In the latter they removed the thickened membrane, and hoped that healthy membrane would grow. If not, they had to curette again. Atmocausis, however, destroyed the membrane and tissues of the uterus, and the depth of the slough depended on the heat of the steam and the duration of the application. If they did not get a sufficient slough the first time they had to repeat the application. In an old woman the obliteration of the uterus, which atmocausis was apt to cause, was desirable. He thought it was a very good method, and it was not so severe as hysterectomy.

Professor ALFRED SMITH said the effect of atmocausis was rather speculative, and in the great majority of cases they would find the best treatment to be

removal.

The President said that on two occasions he "atmocaused" two young women twice each, after they had been curetted ineffectively. The atmocausis failed on the first application and succeeded on the second in each case. He seldom "atmocaused" for more than fifteen seconds. It was better to do too little than too much, and on the second occasion they

might give twenty seconds with better results.
Dr. Sheill exhibited an improved material for liga-

turing the umbilical cord.

ADJOURNED DISCUSSION ON THE OBSTETRICAL AND GYNÆ-COLOGICAL REPORTS OF THE ROTUNDA HOSPITAL.

Professor ALFRED SMITH said that there was little difference between the report and those of twelve vears ago. Recent reports seemed to have become stereotyped. The present report, as a record of work done, was excellent, but he found that, for example, in the important subject of eclampsia, it showed no advance on what had been long published. They had been encouraged last year to hope for much from publication, but the subject was not mentioned in the report, and there was no furtherance of their knowledge as to the use of the operation in cases in which it was recommended. It was a most striking fact that the work done in the extern and intern departments was practically the same as regards results. Such a fact reflected great credit on all concerned, and was an immense change from olden times, when it was safer to be confined outside a maternity hospital than inside it. He thought the morbidity was high in operative cases in which the greatest possible care was

Sir William Smyly thought it was a very good thing that the report had assumed a stereotyped form, as it enabled them to make comparisons, and to note advances such as report showed. In 1886 there were four deaths out of fifteen abdominal sections; in the present report there was one out of ten times that number: that was a remarkable advance. In rupture of the uterus one thing in favour of gauze was that it could be used anywhere. If it only gave as good results as abdominal section it would be more useful to general practitioners. In pelvic deformities it was difficult to impress on men that they would not succeed in extracting a child, no matter what force was used, unless they waited until the head had passed the brim; if it would not pass the brim it was not a case for forceps. He thought the report was the very best he had seen, both as to the matter it contained and the way in which it was brought out.

Dr. KIDD expressed extreme interest in the account of the treatment of rupture of the uterus, as he had seen cases in which unfavourable results had followed an attempt to relieve the patient by abdominal section, and he would be inclined to follow the course adopted by Dr. Tweedy. The case of pernicious vomiting seemed to him to differ very much from the classical symptoms of the condition, as the patient was described as being highly neurasthenic, and having had a fright. There were 235 abortions in the extern department, and only forty in the intern, although the total numbers attended were practically the same in each department. He thought that was due to women staying at home in preference to going to the institution. He observed that there were three and a-half times more adherent placentas in the extern than in the intern department. Probably undue efforts were made to expel the placenta, with the result that the uterus was probably made to contract and incarcerate

the placenta, and the student may have rushed to the conclusion that it was adherent. He thought the morbidity table served to emphasise the danger of the introduction of the hand into the cavity of the uterus. When internal version was resorted to the mortality increased in accordance with the amount of hand and arm introduced.

Dr. SPENCER SHEILL said he did not think the death in the case of Cæsarean section could be put down to obstetrical shock. It was significant that the dilated condition of the uterus preceded rather than

followed the general shock. Under the headings of "Pernicious Vomiting" and "Eclampsia" it was mentioned in the report that the urine of the patients contained albumin, but there was no mention of the output of urea or ammonia, which is considered to be of importance in diagnosing the severity of a case. H= (Dr. Sheill) makes a practice of estimating the output of urea on the appearance of the first sign or

symptom of toxemia, and finds it of great value. Also in pernicious vomiting, if the percentage of ammonia reaches eight or ten of the total nitrogen excreted, then it is an indication for emptying the uterus.

Dr. Pure or said he would not at that late hour occupy the time of the Section with lengthened remarks on this most excellent report. He wished to point out that there was no figure on the cover or in the body of the report indicating the year to which it referred. The absence of some tables generally present in former reports, and useful for purposes of comparison, was reports, and useful for purposes of comparison, was to him a cause of regret. In applying a gauze tampon in cases of rupture, he disapproved of the method advised by Dr. Tweedy. The gauze should be introduced gradually, guided by the fingers of the left hand, using enough to act as a drain, but not so much as to prevent the gradual closure of the rent. Dr. M'Clintock's paper on rupture of the vagina is well worthy of perusal.

Dr. Holmes said the carcinoma cases made a remarkable record, and showed how fine the technique of

the hospital is.

Dr. Nell said he was present at the Cæsarean section already mentioned. At the first look he section already inentioned. At the hist look in thought the patient was suffering from the anæsthetic more than from anything else; but she was a very badly formed woman. He had seen cases of rupture in which hysterectomy had been done unsuccessfully, and he had seen cases in which plugging was very successful. It was creditable to see eight cases of placenta prævia without maternal death, but there were many cases of death of the child. The tearing of the placenta took away any chance the child might have, as it would bleed to death through the placenta.

Dr. TREVOR SMITH said the case of Cæsarean section was not at all a healthy woman, and the death was due, in his opinion, to the anæsthetic, but not through

que, in nis opinion, to the anæsthetic, but not through any fault of the anæsthetist.

Dr. Jellett said there were very few reports of any hospital of the kind that could produce the statistics shown in the tables of eclampsia and Wertheim's operation. They stood out as important proofs of what could be done by careful treatment and processful operation. He thought there was nothing successful operation. He thought there was nothing so important as keeping reports stereotyped for purposes of comparison, though not excluding fresh matter. He observed the omission of some tables which were formerly included, such as those on pro-lapse of the cord, post-partum hæmorrhage, and the sex of twins. In the table of placenta prævia there was a case of a central placenta prævia which was noticeable as to the fœtus being born alive, and he would like to know if the placenta was perforated, and what its position was. He had not done Lawson Tait's operation, in the exact way described by him, for a very long time. He always looked for the levator ani muscle and brought it down. The proportion in which it could not be found was very

The Master of the Rotunda, in reply, said he made it his object to take up one or two fresh subjects in each report, and he had dealt with the treatment of eclampsia the previous year. His mortality was 11 per cent., as compared with 35 per cent. twenty years ago. He had not dealt with publictomy, as they had not had a case during the year. He dealt with it fully last year, when they had five cases. He preferred Cæsarean section as an easier and safer operation if he got the case in time. His indication for performing publiotomy arose when he was sure he could not get a living child save by enlarging the pelvis. Ether was used in the case of Cæsarean section that died. It was an extraordinary uterus, thin-walled and flabby, yet without hæmorrhage. The placenta was firmly adherent. Professor Smith was surprised that they should have a greater morbidity after the application of forceps than in normal delivery. They, however, maintained that the less they interfered the smaller the morbidity. In spite of all precautions they could not get as small a rate of morbidity as when they left the patient alone, which proved that they had not reached the perfection of obstetrical technique. They had estimated the free urea and urea in its form of ammonia, but it had not led them to any conclusion. Others were working on the subject, and they would be glad to learn from them. Without doubt the less experienced a man was the more cases of adherent placenta he would meet. He had not seen a table of placenta prævia that did not show a big infantile mortality, and he had seen none that was less than their own. The child was probably dead before they began to turn. It was usually a premature child, and he was afraid they would always have a high mortality no matter what treatment they adopted. In the central case they went through the placenta. The foot was brought through the rent; the child did not bleed to death, as the placental hæmorrhage was stopped by the leg that was pulled through the hole.

Paris, April 18th, 1909,
TREATMENT OF GOUT BY ARTICULAR PUNCTURE. SINCE 1795, when Tennant and Pearson discovered the presence of uric acid in the articulations of

patients suffering from gout, and more especially since the memorable treatise of Garrod, the majority of authors have admitted that gout is due to an exaggerated production of uric acid in the organism or a rupture of the equilibrium established between the a rupture of the equilibrium established between the production of this acid and its elimination. Guided by this principle, MM. Lumiere and Gelibert considered that it was not sufficient to facilitate the elimination of uric acid by the natural outlets, that it was better practice to extract it directly from the large joints. A puncture made according to the rules of asepsy could cause no risk to the patient. Accordingly, said these authors before the Société de Thérapeutique, for the last five years, each time that the opportunity presented itself, they systematically tapped the knees of gouty patients with constant success. success.

Success.

The immediate results of the operations were: Sudden suppression of pain, rapid fall of temperature, definite termination of the attack. The relief following the puncture was almost instantaneous. As soon as the evacuation of the effusion was effected, the patient could move the limb freely without any pain and considered himself cured.

It is not that hydrarthropic of the knee in patients.

It is rare that hydrarthrosis of the knee in patients It is rare that hydrarthrosis of the knee in patients suffering from gout is not accompanied by a rise of temperature, either locally or generally. A few minutes after the operation it begins to fall, and at the end of three or four hours the temperature is normal. That the liquid is the direct cause of the fever is placed beyond doubt, as MM. Lumiere and Calibert injected as small quantity into animals and Gelibert injected a small quantity into animals and found that the temperature rose 2 or 3 degrees in a

In very acute forms of hydrarthrosis, due to gout, the tapping of a large joint terminated the attack. Where the effusion was absorbed automatically, other joints were attacked in succession, and the malady

dragged on for weeks and months until the reappearance of the hydrarthrosis, when the above operation finally dissipated all accidents.

As to the moment for practising the tapping of the joint, the authors recommend that it should be done as soon as the presence of liquid is clearly diagnosed, without waiting for complete distention of the synovia, as the liquid might become absorbed in a few hours. The most favourable point for introduc-ing the needle would be the external border of the patella. In any case, puncture of the cul de sac beneath the triceps should be avoided, as it is generally independent of the large articular synovial membrane.

The instruments necessary to the operation are simple: An aspirator, Roux or Potain, with a capillary needle of two and a-half inches. The quantity of serosity withdrawn varies between one and four ounces. When the instrument is withdrawn a piece of cotton moistened with collodion and iodoform closes the little aperture, and the knee is enveloped in cotton wool fixed by a bandage. The patient is enjoined to keep his bed two or three days. The distant results of this treatment are important. Patients affirmed that these attacks were much less frequent and less violent. One man had eight or ten attacks yearly for thirty years; after the first tapping he passed two years without a seizure.

Another important point is that no deposits form in the articulations. After the puncture the articulation becomes as free as before the attack, while no gouty concretions form on the fringes of the synovial membrane nor on any part of the body, whereas, under the classical treatment, such deposits of urates are the rule, amounting in many cases to

established infirmity.

The liquid withdrawn from the joint is of citron yellow, and contains chloride of sodium, phosphates, and traces of sulphates and carbonates. Urea varies in considerable proportions, but no uric acid has been

The liquid is eminently toxic; injected into the veins of a rabbit, in doses varying between one and two drachms per lb. weight of the animal, it killed it in a few hours after provoking a considerable rise in the temperature.

To conclude, MM. Lumiere and Gelibert affirm that from the constancy of the results obtained, the sim-plicity and benignity of the operation, articular puncture constitutes, in every case where it is pos-sible, the best curative treatment of an attack of

SYPHILITIC INFANTS. Prof. Comby, the well-known authority on children's diseases, recommends the following method of treating hereditary syphilis in infants:—Friction during five minutes each day with a flannel on which is spread mercurial ointment of about the size of a small nut. The regions successively chosen are the right and left side of the abdomen, both axillæ, the right and left inguinal regions, the internal surface of the thighs, so as not to return for eight days to the place already treated.

The flannel should be left in situ after each friction. After twelve hours the region should be washed with soap and water. During the first year the ointment should be applied daily, with an interruption of a fortnight every three months. The second year, one month's treatment and one month's rest. During the first months a little of the following ointment should be introduced into each nostril morning and evening:

Calomel, ½ dr.
Vaseline, 1 oz.
If there are papulæ on the skin, a bath of sublimate should be given daily for ten days:

Corrosive sublimate, ½ dr. Hydrochl. of ammonia, 1 dr.

The immersion should last ten minutes, at a tempe-

rature of 95°.

Prof. Comby never observed any accident with this treatment, which was always successful.

LIEUTENANT-COLONEL J. D. LLOYD, of Chirk, has received from the King the newly-instituted Territorial Decoration for long and meritorious service.

#### GERMANY.

Berlin, April 18th, 1909.

AT the Verein für Innere Medizin, Hr. His read a paper on

GOUT AND RHEUMATISM.

He said, by way of introduction, that the classification of the chronic arthritides had ever been a crux medicorum. It could not be undertaken without a certain caprice, whence arose the confusion of the nomenclature, which corresponded to the prevailing views as to ætiology and pathology, and the treatment. They were considered as diseases of tissue change, and treated dietetically and by appropriate medicines. If we went back to modern history we saw that in the first half of the last century, in France, the idea of arthritism was formulated, of which all the various manifestations formed a part. About the middle of the century general interest turned to this subject, and excellent monographs appeared, amongst which that of Garrod was to be specially mentioned, the great value of which was that it severed gout from the common conception. Later the essential part of the chronic joint affections was announced to be a failure of purin tissue change, and precision was attempted by means of investigations. Undoubtedly in these diseases uric acid was the material that could be grasped, but it was not the only materia peccans, for we found a number of symptoms that had nothing to do with it. Perhaps toxic products made their appearance in the diseases of purin tissue change. It might be a general disturbance of the organism; the affection might depend on an improper mode of life, from excesses in eating, and the use of spirituous liquors. Observation of numerous cases, however, taught that patients did not always get worse, and so that we were compelled to assume a certain congenital

or acquired tendency.

Was the disturbance of purin tissue change the only disturbance? We found in connection with arteriosclerosis, obesity, diabetes, etc., for which reason the idea of a constitutional disease was retained. In opposition to this, Virchow especially had given prominence to the anatomical idea, and defended the notion that these were only diseases of organs, the rôle being played in the cells. Now it was at least probable, but by no means proven, that anomalies of the cells were the foundation of disease, but which were not visible to the eye. Ottomar Rosenbach and Martin had now added new contents to the idea of a constitutional disease; to it belonged idiosyncrasy, immunity, etc. But a certain disposition to forms of disease which we call a diathesis could not be denied. Wherefore, the French idea of arthritism had been retained and developed, and had now been accepted by the physicians of North America and Italy. It had now attained excessive dimensions; everything relating to constitutional anomalies was grouped within it. Quite recently it had been more sharply defined in Lyons as a condition in which uric acid and oxalic acid were present in the blood, or there was a diminu-

tion of oxydation.

The chronic arthritides might appear in manifold form. From clinical points of view we might divide them into:—(1) Chronic affections of joints after acute articular rheumatism, secondary chronic articular rheumatism; (a) primary chronic polyarthritis, (a) with exudation in the cavities of the joints and synovial growths, (b) without these; (3) the chronic arthritides peculiar to old age; (4) the traumatic form; (5) Heberden's nodules. From the anatomical point of view we distinguished (a) diseases that began in the cartilage, in which the capsule was but little and secondarily affected; (b) diseases that began in the and secondarily affected; (b) diseases that began in the synovia, and passed on to the bones secondarily. Ætiologically we distinguished diseases: (1) from injury and after hæmorrhages and inflammations, etc.; (2) after acute rheumatism; (3) after infectious diseases, such as scarlatina, typhoid, pneumonia, etc., and especially after chronic infectious diseases, such as gonorrhœa, syphilis, tuberculosis. As regarded the latter, its causative rôle must be considered doubtful, notwithstanding the fact that in this respect it was given a prominent place by many authors. The frequent occurrence of endocarditis was very reminiscent

of infection, although specific bacteria had not yet been found in it.

After taking away the cases with a known ætiology, there still remained a large number in which no ætiological trace could be discovered. When now hereditary or family tendencies as to gout and chronic arthritides had been observed, we could then speak of a diathesis. This was so especially as regarded Heberden's nodules, which bore a relation to the endogenous diseases.

How, then, could the idea of a common cause be more sharply defined? Firstly, by anatomical examination. It was often seen that in diseases that must be reckoned as arthritisms there were arthritic changes in the joints. In 97 cases of the kind examined by the speaker, such degenerations were found in 62, and not infrequently in very young people, under the influence, therefore, of some injury of nutrition of the cartilage

of nutrition of the cartilage.

A further question was whether the purin tissue change in these patients showed any deviation from the normal. He was able to prove the deviation in six of the cases examined, amongst others in an old drinker who had formerly had attacks of gout, in one case with arterial hypertension, in two females with progressive ineumatism, and in one alcoholic with sciatica.

The speaker then proceeded to the differential diagnosis between gout and rheumatism. There were two methods of investigation at hand—(1) Examination by Röntgen rays, and (2) examination of the purin tissue change. The first-named method was first recommended by Potain. He described lacunæ in the bones as a characteristic sign of gout. The speaker could not recognise this as a characteristic of gout, as, according to his own investigations, such lacunæ were present in bones in chronic arthritis and in the non-arthritic (illustrations of preparations were here shown on the screen). On the other hand, examination of the purin changes yielded a good mark for the differential diagnosis between gout and rheumatism. Where changes of purin tissue change could be proved, the case was one of true gout.

What therapeutical consequences might be drawn from the foregoing considerations? Very many physicians ordered a lacto-vegetable diet in these groups of diseases. It must be conceded that in the case of strong people we got a favourable effect in this way, but in the severer forms we might easily set up a condition of defective nutrition, which in weakly people was very dangerous. In true gout a purin-poor ciet was indicated.

#### AUSTRIA.

#### Vienna, April 18th, 1909.

WORKERS' TETANY.

Two cases of tetany due to the occupation of the patients were presented to the members of the Gesell-schaft der Aerzte by Falta and Rudinger, which were interesting subjects for discussion owing to the experimental treatment with adrenalin. Tetany is still in the chrysalis stage respecting its ætiology, and each investigator adds a qualifying term to convey his own opinion.

Jaksch and Frankl-Hochwart have repeatedly affirmed that shoemakers are more subject to this disease than others. They found by investigation that out of 314 males affected, 141 were shoemakers, and 41 tailors, hence the term "schusterkrampf."

Whether this incidence is due to the nature of the work, or whether the atmosphere and surroundings favour the formation of the noxe, none seem yet to be able to explain, which largely accounts for the increase of our terminology. Genuine tetany, according to the experiments of Eiselsberg on animals, can be produced by the extirpation of the thyroid, and Billroth's operations on the human subject confirmed this opinion; but how the mucin accumulates in the body by any particular trade is not yet clear. Falta and Rudinger were anxious to test the circulation, and, with this in view, injected adrenalin. In the normal subject 1 milligramme, when injected subcutaneously, raises the pressure suddenly. In ten normal cases he

injected, eight of them rose to their maximum within 6 and 8 minutes, and, according to Riva-Rocci's method, would support 30 to 60 milligrammes, or 11.8 to 23.6 in. of mercury. This exalted bloodpressure will last a quarter to three-quarters of an hour, and then gradually subside.

In four cases of tetany so treated the results were variable. In all the cases the blood pressure rose to its maximum within 2 to 3 minutes, and in one of the cases presented the pressure supported oo to 180 millimetres of mercury, equal to 34 or 70.8 in.; in the other case the pressure ranged between 115 to 165 millimetres, while the others varied between these extremes. After the injections there was an exacerbation of the tetanic contractions, as well as the prominent symptoms of Chvostek and Trousseau. All had parasthesia, with cramping in the hands, but not so great in the lower extremities. The contractions were lighter in the muscles of the abdomen and glottis, though sometimes dangerously severe.

#### Loss of the Feeling of Touch.

Flesch brought in a peculiar case of teleangiectasis causing the loss of the feeling of touch in the fingers. The patient, a male, æt. 56, had a large teleangiectatic swelling, extending from the right eyelid back across the parietal bone to the occipital; the right eyeball was deeply depressed in the orbit, surrounded by a convolution of veins almost fixing the movement of the bulbus, while the pupil reacted normally. Over the upper part of the nose there was also a doughy swelling, but firm beneath when pressed. On closer examination the whole of the parietal bone seemed to be absorbed on the outer surface, exposing the diploë. From the elastic wave, on deep impressions, it was concluded that the parietal bone was entirely absorbed or transformed to a fibrous covering for the cerebrum. There were also large convolutions of veins in the naso-pharyngeal space hanging down like grapes behind the gums. When the jugular vein was slightly compressed the caverns of blood were enormously increased, causing fulness and vertigo. When the head was lowered or compressed, there was a feeling of fulness while coughing made the veins jump up.

From this inquiry the connection between the hand and angioma became clear. It appears this racemose angioma had been there for years, and had acted on the diploë till it became absorbed, after which the arachnoidal vessels would be affected, and finally the cortical substance of the brain, with the subsequent lesion of paralysis of feeling in the hands.

#### ANAPHYLAXIS.

Biedl and Kraus gave the members of the Gesell-schaft an exhaustive account of their laboratory experiments with peptones, particularly Witte's peptone, which contains 70 to 80 per cent. of the substance. By ir jecting this peptone an antiphylaxis for serum was induced. When the animal was saturated with the anaphylactic toxine it was insensible to the Witte peptone injections. They thought this did not prove that the toxines were alike, but it showed they were nearly related in some way. The hypothetical toxine of anaphylaxia and Witte peptone are physiologically related by the mode of attack, both paralysing the peripheral vasomotor apparatus with non-coagulation of the blood. The negative action of anti-anaphylaxia and immunising peptones shows that new toxines have no effect on the paralysed muscles. The paralysis gradually recovers, and the blood pressure returns to its normal state, but the weakness is easily induced by interfering with the spinal cord or splanchnic nerve. They concluded by reiterating that anaphylactic intoxication was physiologically identical with the Witte peptone toxine.

Escherich was of opinion that the serum disease had a great similarity to peptone intoxication, as shown by Pirquet and Schick. They showed that any foreign serum when injected liberated analbuminoid serum that was readily thrown off.

Biedl said the anaphylactic reaction liberated an anaphylactic toxine, which acted as an anti-anaphylactic on other serum, while the peptone produced a sort of degenerate product which had the property of increasing the sensibility of other animals.

#### LETTERS TO THE EDITOR.

[We do not hold curselves responsible for the opinions expressed by our Correspondents.]

THE POOR-LAW MEDICAL SERVICE.

To the Editor of The Medical Press and Circular. SIR,—There was a day not so long ago when to have the Times on one's side in any project of reform affecting the welfare of the people was to make tolerably sure of ultimate victory. Editorially the Times is as strong as ever; but from causes that you, Sir, on several occasions have sufficiently pointed out, the prestige of the erstwhile leading journal has gone; and an article powerful as it may inherently be from its matter and literary form now effects little more in the way of influencing public opinion than the spicy paragraphs of the most vulgar of half-penny contemporaries that is written down to the level of the intellect of 'Arry. In the Times of to-day appears a most admirable article on Dr. McVail's report which has been already noticed in your paper. The article fully exposes the enormous waste of power and money involved in the present system; and the lamentable loss of efficiency from the failure to regard the provision of medical attendance for the sick poor as a matter of national concern, likely to exert an appreciable influence upon the national welfare. appreciable induence upon the national weitare. The miserable position of the Poor-law Medical Officer is clearly exposed. There are no graduations of rank among its members; no official recognition of good work, no condemnation of inefficiency or neglect. The Poor-law Medical Officer is at present the servant of the Board of Guardians; and the Boards are too often dominated by mean, ignorant, and selfish men incapable of understanding the importance of the laws they are supposed to administer, or ance of the laws they are supposed to administer, or capable of obstructing their enforcement to further their own sordid ends. They have ample power to coerce their officer into docility. He must obey or go. There is no public opinion to appeal to with effect. The case for Poor-law Medical Reform, like the case for medical law reform all through, the case for reasonable treatment by the State of all its medical servants, and of all medical practitioners from whom it exacts so much—the case for justice to the profession is overwhelming. It is the fault of the profession that reform does not come. It is their duty to the State, and to the masses whose sufferings from the present condition of things they alone are fully cognisant of, to force the facts to the front, and demand reform. Would that I could see any signs of movement in this direction among the profession. Until such signs appear I must, I fear, continue to sign myself,

April 15th, 1909.

A Poor Parish Doctor.

# MILITARY & NAVAL MEDICAL NOTES.

A BLOCK at the Military Hospital, Hilsea, is to be built at a cost of  $\pounds 3,150$ .

LIEUTENANT-COLONEL R. E. MONSE, R.A.M.C., has been appointed to charge of the Military Hospital, Cosham, Hants.

SURGEON-GENERAL P. H. BENSON, I.M.S., has been awarded a good service pension in succession to Surgeon-General J. P. Greeney, retired.

Dr. W. S. A. GRIFFITH, Phys. Accoucheur, St. Bartholomew's Hospital, has been appointed by the Army Medical Council Consulting Gynæcologist to Queen Alexandra's Military Hospital.

A BOOK of some importance to officers and soldiers serving in India has been written by Major R. J. Blackham, R.A.M.C., Divisional Sanitary Officer, Peshawar. Its title is "Military Sanitation for Soldiers Serving in Hot Climates." It is specially

intended to aid officers studying for subject J, and will contain sections on communicable diseases of soldiers, air, water, food, clothing care of barracks, the camp, and the march, disinfection and disinfectants, etc., etc.

MAJOR G. CRAWFORD, R.A.M.C., recently gave a very interesting address at the Soldiers' and Sailors' Institute, Valetta, Malta, on his experiences while in command of the Field Hospital which was despatched to Messina after the earthquake to afford aid to the sufferers.

THE Pasteur Institute in Burma has received subscriptions amounting to one lakh and 17,000 rupees. The benefit derived by the population, civil and military, from these institutions throughout India is very great, and it is not surprising to find subscriptions flowing in so generously.

SURGEON GERALD C. CROSS, Royal Navy, having completed two years' service as junior medical officer at Sheerness Dockyard, is succeeded by Surgeon E. R. Townsend, Royal Navy, who is completing a three months' course of study at a civil hospital. Surgeon G. C. Cross joins the torpedo-gunboat Leda.

THE discontent among sailors of H.M. ships of war regarding hospital stoppages led to a question being asked, in the House of Commons, by Sir John Benn, of the First Lord of the Admiralty as to whether the latter was aware of the resentments in regard to these stoppages in cases where illness was not in any way attributable to the misconduct of the patient, and whether the First Lord would make inquiries with a view to remedying the alleged grievance. Mr. McKenna (the First Lord of the Admiralty) said that the subject was now being considered by the Board of Admiralty.

Gratifying results have attended the movement for inducing officers and men in the Dockyard at Devon-tort to go through a course of instruction to qualify for the St. John's Ambulance Association Certificate. The first class was formed by 16. of whom 13 went in for the examination with 10 successes for "First Aid" Certificates. Praise is due to Engineer-Commander Emdin, at whose invitation Major H. Blackman, R.A.M.C., delivered two explanatory lectures with lantern views. The examination was conducted by a retired Deputy Inspector-General, Royal Navy, Dr. Coates, of Dawlish.

The usual hustle and bustle of Army Medical Mobilisation seems to have occurred in Vienna during the Servo-Austrian scare. Certain defects in the Medical Corps of the Austrian Army were exposed some little time ago, particularly the insufficiency of staff surgeons. Haste was made to put things right and up to modern requirements. All practitioners between 24 and 36 years were warned to re-enter the Army. In the Austrian Army, on mobilisation, one surgeon is allotted to 200 men—about 30 per cent. of the civil population doctors are withdrawn on mobilisation.

#### **OBITUARY.**

CLAUDIUS GALEN WHEELHOUSE, F.R.C.S., LL.D., D.Sc.

MEMBERS of the medical profession in general will share the regret which the citizens of Leeds felt at the death, in his 83rd year, of Mr. C. G. Wheelhouse, who, after nearly half a century's strenuous work, retired to enjoy well-earned rest in his country home at Filey in 1889.

Claudius Galen Wheelhouse, F.R.C.S., LL.D., D.Sc., was the second son of Mr. James Wheelhouse, surgeon. On October 1st, 1846, young Wheelhouse, already an ardent student, took his place on the benches of the Leeds School of Medicine, where he remained for three years. During his

connection with the Medical School, Mr. Wheel-house, filled in succession the Chairs of General Anatomy, Physiology, and Surgery, and he also found time to engage largely in private tuition. For many years few of the pupils of the Leeds School of Medicine presented themselves for examination at the Royal College of Surgeons until they had his assurance that they were fit to do so, and even to this day many of his old pupils will remember with gratitude the care he took in their preparation. The high posi-tion to which the Leeds School of Medicine attained was to a very large extent due to the unremitting zeal which Mr. Wheelhouse took in nursing the institution through its early difficulties, and he is pronounced by the students of that day to have been one of the best teachers of anatomy, physiology, and surgery that the school ever possessed, his lectures and thorough coaching of pupils being singularly successful. The dacility with which he imparted his knowledge on any subject, as lecturer or in private, was extraordinary. On two occasions he held the position of President of the School, and from first to last, for a period of twenty years, he took the deepest personal concern in everything that has helped to make this medical academy an institution of which Leeds and the whole

country are justly proud.

In March, 1864, he was elected, with the late Mr.

Nunneley and Mr. T. Pridgin Teale, Surgeon to the
Leeds Infirmary, an office which he retained for

twenty years.

When, in 1885, direct representation of the profession on the General Council of Medical Education and Registration was, after long-continued agitation in Parliament, at last obtained, he was elected at the head of a large poll of the whole profession the first direct representative for England. This honourable position he held for ten years, and only relinquished it when advancing years warned him that the duties could be better performed by a younger man.

#### JAMES O'BRIEN KOUGH, M.R.C.S., L.S.A.

WE regret to record the death, on April 2nd, at Wolverhampton, of Dr. James O'Brien Kough. The deceased gentleman was trained for the medical profession at St. Bartholomew's Hospital, London, and became a licentiate of the Society of Apothecaries of London in 1860, and a member of the Royal College of Surgeons of England in 1861. He had thus been a registered medical practitioner for nearly half a His first medical appointment was that of century. Assistant House Surgeon of the Salop Infirmary, and next he was House Surgeon of the Wolverhampton and Staffordshire General Hospital, and subsequently one of the honorary surgeons of the institution. For many years he had also been in private practice in Wolverhampton. It may be mentioned that he was an old Shrewsbury schoolboy, to which school he was sent by the late Sir James Paget. There he formed lasting friendships with many men who have since risen to eminence. Mr. Kough was personally acquainted with many men whose names are Lousehold words, such, for example, as Charles Dickens and Charles Darwin. He was an intense lover of Nature, and an ardent horticulturist. He had an extensive, varied, and highly interesting collection of exotic plants in cultivation—in fact, it is doubtful if a much more interesting private collection of horticultural specimens under glass could be found in the Midlands.

#### ROBERT JAMES CARTER, M.D.LOND.

THE death of Dr. Robert James Carter has taken place at his residence at St. John's Wood, N.W., at skin Hospital and a House Surgeon at the Soho Male Lock Hospital. Formerly he had held appointments as Resident Medical Officer at the Royal Hospital for Children and Women, Clinical Assistant at the Evelina Hospital, House Surgeon at King's College Hospital, and Surgeon to the Clan Line Steamship Company. His medical education was carried out at King's College Hospital, whence he took the degree of M.B. Lond., and where he was a popular and well-known student.

EDWARD PENROSE TWYFORD, M.D.ED., J.P. WE regret to announce that Dr. E. P. Twyford, J.P., late of St. Helens, died, on April 8th, at his residence at Birkdale, Southport. Dr. Twyford had been taken ill on April 1st, when his only daughter died from pneumonia. This sad event had a distressing effect upon Dr. Twyford, who would have completed his 78th year next month. He developed pneumonia, and it was soon evident he was in a hopeless state. Twyford had been in practice at St. Helens over 55 years, and he was a county and borough magistrate, and widely respected.

#### THOMAS WILLIAM NUNN, F.R.C.S.

WE regret to announce that, after a short illness, Mr. Thomas William Nunn, consulting surgeon to the Middlesex Hospital, died of heart failure at Kneesworth, Royston, last week. Before being appointed to the medical staff of Middlesex Hospital, Mr. Nunn was surgeon to the Westminster Western Dispensary, and in later life was also a consulting surgeon to the Central London Throat Hospital and to the London Hospital for Skin Diseases. He saw a great deal of early practice in Paris, where he was at the time of the Commune. He was formerly a lieutenant of the 3rd Middlesex Militia and hon. surgeon-major of the Volunteer Forces. He contributed various papers to medical literature, his chief contributions being those relating to the treatment of cancer, and in 1899 he published in book form the reports of 1,000 cases from the registers of Middlesex Hospital. Mr. Nunn was a past Vice-President of the Pathological Society and a medical associate, and member of the teaching staff of the anatomical department of King's College. He qualified as a member of the Royal College of Surgeons in 1846, and as a Fellow in 1857, and was 84 years of age.

#### CHARLES BELL TAYLOR, M.D.EDIN., M.R.C.S. ENG.

We regret to announce the death of Dr. Charles Bell Taylor, of Nottingham, who for many years was in practice in the Midland Counties as an ophthalmic

Dr. Taylor was the son of a veterinary surgeon of Nottingham, and received his medical education at the University of Edinburgh and in Paris. He became a member of the Royal College of Surgeons of England in 1852, and M.D. at Edinburgh in 1854. In 1859 he was appointed a surgeon to the then newlyestablished Eye Infirmary at Nottingham. Dr. Taylor entered upon the work of his speciality at a time when it was undergoing great changes as a conse-quence of improved methods of investigation, and for fifty years he kept himself well abreast of its advances, whether as regards science or practice. Notwithstanding his advanced age, he continued to see patients, and he was quite recently consulted by "General" Booth, and advised the operation which has since been successfully performed. Dr. Taylor was unmarried. He made many contributions to current medical literature, and was the author of a book of "Clinical Lectures on Diseases of the Eye."

SIMEON SNELL, F.R.C.S.Edin., M.R.C.S.Eng., J.P.

We regret to announce the death of Mr. Simeon Snell, the well-known ophthalmic surgeon, of Sheffield, on Saturday last. Deceased, who received his medical education at Leeds and at Guy's Hospital, London, took the M.R.C.S.Eng. in 1872, and the F.R.C.S.Edin. in 1892. He held many ophthalmic appointments, including that of the Royal Infirmary of Sheffield. At one time he edited the Quarterly Medical Journal, and was the author of numerous medical treatises and several books. Some of his best known work was that connected with miners' nystagmus. Among many honorary posts filled with distinction by Mr. Snell were that of President of the Ophthalmological Society and of President of the British Medical Association (1900). In our next issue we hope to give a more extended notice of his busy and useful career from the pen of a personal friend.

### MEDICAL NEWS IN BRIEF.

#### The Tuberculosis Exhibition

THE Tuberculosis Exhibition, inaugurated by the Women's National Health Association, will be held in the Rotunda Rooms (not in the Rotunda Hospital, as announced by a contemporary), from April 20th-22nd. At a meeting already held the following execu-Fannin, and Mr. T. C. Harrington, M.P., Honorary Secretaries; and at the following executive officers and Mr. J. C. Harrington, M.P., Honorary Secretaries; and at the following meeting of the Executive Committee (co. Avril 18th) the project secretaries. Executive Committee (on April 7th) the various sections of the Exhibition were allocated to managers and sub-committees as follows:—Pathological Section, Professor E. J. McWeeney. Veterinary Section, Mr. C. Allen, Mr. A. Watson, and Mr. J. Wilkinson; Statistical Section, Sir R. E. Matheson; Literature Section, Dr. A. G. Boyd; Appliances Section, Sir W. J. Thompson; Hygiene Section, Mr. George Fletcher, Dr. R. J. Rowlette, and Professor F. T. Heuston. Food Section, Professor W. H. Thompson; Domestic Science Section, Professor W. H. Inompson;
Domestic Science Section, Mrs. Rushton, Miss Fletcher,
and Miss McNeill. It was then announced that Dr.
E. W. Hope, Superintendent Medical Officer of
Health of Liverpool, would deliver a lecture on Tuesday, April 20th, and that Dr. Philips would lecture on the following evening. It was also decided that popular lectures should be delivered every evening, and that demonstrations of exhibits should be given frequently during the day.

#### Association of Medical Men Receiving Resident Patients.

THE annual general meeting of this Association was Dr. W. T. Reid in the chair. Dr. G. E. J. Crallan was elected President for the ensuing year, and Drs. Dove, Haynes, Still, Reid and Walsh, Vice-Presidents. The annual report presented by the Secretary was read and received. It showed a very catificatory increase in the work of the Association satisfactory increase in the work of the Association, the number of patients placed being nearly double than those of 1907. The demand for membership, however, was shown to continue to be higher than is commensurate with the applications received from patients. The report showed that, in spite of this encouraging evidence, the Association was far from receiving the support which it deserves at the hands of the profession, as being the only organisation of medical men formed for the purpose and established on the principles of self-help and mutual support, and also that it had nothing in common with commercial agencies, as any profits made became the property of the Association as a whole.

The financial position, which enabled the subscriptions to be lowered last year, shows that, in spite of this fact, and with increased advertising and clerical expenses, the balance brought over at the end of 1908

was almost double that of 1907.
Votes of thanks to the Chairman and Honorary Secretary brought the meeting to a close.

#### London School of Tropical Medicine.

This institution, which is affiliated with the University of London, is about to start an Advanced Course in Medical Zoology on May 1st; this will include Protozoology, Arthropodology, and Helminthology. The second course will commence on October 1st. Students who have attended the ordinary course are eligible, and others who satisfy the teachers in these subjects that they possess sufficient rudimentary know-ledge to benefit by these courses. The advanced course in each subject will begin at the expiration of General Medical Zoology, 1st week of the session; Protozoology, 4th week of the session; Arthropodology, 7th week of the session; Helminthology, 1oth week of the session. Arrangements are so made that the advanced course in all three subjects can be taken during the three months or the whole time may be

spent on one subject. Special arrangement may be made with the teachers where it is desired to spend more time on one branch to the exclusion of others, or to undertake research work in that subject.

Further particulars as to the course of study may be had on application to Dr. C. W. Daniels, Director at the School, Connaught Road, Albert Dock, E., or to the Secretary, at the Head Office, Seamen's Hospital, Greenwich, S.E.

#### National Lying-in Hospital, Dublin.

At a recent meeting of the Board of Governors of this hospital, Dr. Andrew Horne, President of the Royal College of Physicians, and Dr. Reginald White were appointed Joint-Masters for the ensuing seven years. Dr. Horne has already held the post since the foundation of the hospital, and Dr. White takes the place formerly held by Dr. Barry.

#### Royal College of Surgeons in Ireland.—Election of Examiners.

NOTICE is hereby given that a meeting of Fellows will be held on Tuesday, May 4th, at half-past four o'clock, pursuant to the provisions of the Supplemental Charter, to witness the election of Examiners.

Graduates of any University which may be from time to time recognised by the College shall be eligible for election as Examiners in the subjects of General Education. All the other Examiners shall be Fellows or Licentiates of the College, or professors or lecturers in any School of Medicine recognised by the College.

Candidates are requested to lodge their applications in writing with the Registrar, at the College, on or before Tuesday, April 27th, at 10 a.m.

#### University of Durham.

THE following candidates have obtained the Degree of Doctor of Medicine.—Gilbert I. Cumberlege, M.B., B.S.Durh.; Robert A. Morris, M.B., B.S.Durh.; William W. Stainthorp, M.B., B.S.Durh.; Percy E. Turner, M.B., B.S.Durh.

Degree of Doctor of Medicine for Practitioners of Degree of Doctor of Medicine for Practitioners of Fifteen Years' Standing.—Graham T. B. Blick, M.R.C.S., L.R.C.P., L.S.A.; Alfred A. Hill, L.R.C.P. and S., L.F.P.S., G., Ernest W. G. Masterman, F.R.C.S., L.R.C.P., D.P.H.; Edward J. F. Moore, M.R.C.S., L.R.C.P.; John P. Oliver, M.R.C.S., L.R.C.P.; Walter J. E. Sumpter, M.R.C.S., L.R.C.P., L.S.A

The Degree of Master of Surgery (M.S.) has been obtained by Bryden Glendining, M.B., B.S.Durh., F.R.C.S.

The following obtained the Degree of Bachelor of The following obtained the Degree of Bachelor of Medicine (M.B.).—Kenneth Bruce Allan, Harriett Amelia R. Apps, Eldred C. Braithwaite, Leonard F. Browne, Charles E. L. Burman, Leslie W. Evans, John R. D. Holtby, L.R.C.P. and S., E.; Henry F. Iliewicz, M.R.C.S., L.S.A.; Duncan M. Johnston, M.R.C.S., L.R.C.P., D.P.H.; Annie V. Mack, Jessie M. Murray, Friederike Rahtkens, William Rollin, L.R.C.P. and S., L.F.P.S., G.; Robert H. Smailwood (Rev.), M.A.; Theodore W. Stallybrass.

Degree of Bachelor of Surgery (B.S.).—Kenneth B. Degree of Bachelor of Surgery (B.S.).—Renneth R. Allan, Harriett A. R. Apps, Eldred C. Braithwaite, Leonard F. Browne, Charles E. L. Burman, Leslie W. Bachelor of Hygiene (B.Hy.).—Guy R. East, M.B.,

Bachelor of Hygiene (B.Hy.).—Guy R. East, M.B., B.S.Durh.; John T. Johnson, M.D., B.S.Durh.; William R. Macdonald, M.B., Ch.B.Ed.; Elizabeth N. Niel, M.B., B.S.Durh.; Arthur J. R. O'Brien, M.B., Ch.B.Ed.; Gertrude E. O'Brien, M.B., B.S.Durh. And the following received the Diploma in Public Health (D.P.H.).—Guy R. East, M.B., B.S.Durh.; John T. Johnson, M.D., B.S.Durh.; William R. Macdonald, M.B., Ch.B.Ed.; Elizabeth N. Niel, M.B., B.S.Durh.; Arthur J. R. O'Brien, M.B., Ch.B.Ed.; Gertrude E. O'Brien, M.B., B.S.Durh.

#### **NOTICES TO** CORRESPONDENTS. &c.

CORRESPONDENTS requiring a reply in this column are par-ticularly requested to make use of a Distinctive Signature or Institut, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much con-fusion will be spared by attention to this rule.

#### SUBSCRIPTIONS.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dewson and Sons are our special agents for Canada. ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessary for publication but as evidence of identity.

ADVARTICEMENTS.

advarticements.

ADVARTICEMENTS.

For ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, &c. —Seven lines or under (70 words), &s. 6d. per insertion; 6d. per line beyond.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Edutor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office, when sending subscriptions the same rue applies as to office; these should be addressed to the Publisher.

Medicus (Market Harborough)—There is always room for a

MEDICUS (Market Harborough).—There is always room for a practical scheme for the reliet of human suffering. It will be well to take careful precautions, however, that the benefit of one class does not involve any injury to another, least of all to the profession to which our correspondent belongs.

VISITOR (Wimbledon).—The Medical Officer of the district is the proper person to apply to for information. You cannot compel your landlord to undertake the selling right of the drainage, unless you secured a warranty before signing the lease.

G. E. M. (Somerset).—You will find no better climate for your patient than that of the Tyrol. The scenery is magnificent, the air bracing, and the natives a hospitable and charming race. Innsbruck is the capital, and forms an excellent centre for the country. If you write to Herr Karl Landsee, of Innsbruck, Austrian Tyrol, he will supply you with all particulars.

particulars.

EXPERIMENTS IN RABIES PREVENTION.

It may interest readers to learn that some important experiments have recently been made in Southern India by Major Cornwell, I.M.S., and M. Keswa Pai. A virus emulsion of rabies has been exposed for several minutes to the action of cyllin, and injected into rabbits subdurally. The important observation has been made that it is possible, by means of cyllin, to destroy the virus of rabies in from three to five minutes at ordinary temperatures. The outcome of these experiments can hardly fail to be of much scientific interest.

hardly fail to be of much scientific interest.

B.A.M.C.—The term "tropical" is usually reserved for the amœboid form of dysentery, which is endemic in certain countries such as Hindustan, Cochin-China, Algiers, Egypt, and so on. One epidemic form is probably due to the rod-like hacillus, isolated by Shiga in Japan in 1838—the bacillus dysenteries. It is found in the mucous discharges from the outset, and Shiga himself claims to have remarkable results from an anti-dysenteric serum, especially if used at the beginning of an attack.

ning of an attack.

H. J. Rodner.—Yes, such a body is in existence. On June 26th, 1908, an Association of Subscribers to Charities was formed at the Mansion House, London. The avowed intention is to promote systematised co-operation between charities with kindred objects, the establishment of uniform principles and methods among charities in general, the promotion of facilities for interchange of information among charitiable institutions, and the strengthening of the financial position of charities which are endeavouring to carry out the objects of such an association. Hospital Reformer.—That part of our hospital system most urgently in need of reform is the out-patient department. The great drain upon finances thereby created is a serious tax upon the charitable, while at the same time a large amount of legitimate income is withdrawn from local general practitioners.

CROTTS.—On April 17th, at 26 King's Road, Windsor, the wife of A. Douglas Crofts, M.B.C.S., L.R.C.P.Lond., of a daughter.
FRENCH.—On April 12th, at "Rammore," Burgh Heath, Surrey, the wife of Ronald E. French, M.A., M.B., B.C., of a son.

#### Marriages.

LINDSET—CREAK.—On April 17th, at Emmanuel Church, Mannamead, Plymouth, Colin D. Lindsey, M.D., of Blandford, Mannamead, elder son of the late Assistant Commissary General J. L. Lindsey, to Isabel B. Creak, youngest daughter of Colonel Henry C. Creak, Bengal Cavairy (retired).

MKAN—CAMERON.—On April 13th, at St. Peter's Church, Cleathorpes, John Clarke Mead, M.B.B.S.Lond., F.R.C.S., only son of John and Emily Mead, of Watford, to Christina, second daughter of Alexander Cameron, M.D., and Mrs. Cameron, of Cleethorpes.

## Beaths.

BRUNTON.—On April 14th, at 10 Stratford Place, London, after a long illness, Louisn, the beloved wife of Sir Lauder Brunton, Bs., M.D., and daughter of the late Ven. E. A. Stopford, Archdeacon of Meath.

Fraer.—On April 15th, at 5 Tettenhall Road, Wolverhampton, John Fraser, M.D., aged 69 years.

Girmon.—On April 17th, at 39 Oxford Terrace, Hyde Park, Septimus Gibbon, B.A., M.B.Cantab., in his 84th year.

NUMN.—On April 13th, at The Gaunt Tower, Kneesworth, Boyston, from heart failure, after short illness, Thomas William Numa, F.R.C.S., of 27 York Terrace, London, Consulting Surgeon to the Middlesex Hospital.

TATIOR.—On April 15th, at his residence, Beechwood Hall, Mapperley, Nottingham, Charles Bell Taylor, M.D.Edin., F.R.C.S.E.

"A distinct advance on Easton's Syrup."

YNIN' AMARA is an analogue of Easton's Syrup, in which the sugar is replaced by an active Malt Extract. This affords a far better vehicle than syrup, as it is actively digestive and nutritious, and there is not the likelihood of the sugar crystallizing out, and carrying down in the crystal the alkaloid principle.

As a digestive tonic, therefore, 'BYNIN' AMARA is not only safer to take than Easton's Syrup, but is of greater value both in aiding and strengthening the powers of assimilation.

It has been found very effective in neuralgia and similar nerve troubles.

#### -COMPOSITION.

 Quinine Phosphate
 ...
 ...
 ...
 ...
 1½ grains.

 Iron Phosphate
 ...
 ...
 ...
 2
 ,,

 Nux Vomica Alkaloids equal to Strychnine
 ½ 6

# Influenza?

The present mild outbreak of "influenza," in which gastric and intestinal symptoms are prominent, may be combated to a large degree by efficient intestinal antisepsis. These symptoms are indisputably those of fermentation, of bacterial origin. It is not necessary that the influenza organism (Pfeiffer's bacillus) should reach the gastric and upper intestinal regions to effect such troubles, as the devitalising influence, produced generally by the growth of this bacillus in any part of the body, affords free opportunity for the untrammelled activities of certain intestinal organisms which in health remain in a state of inhibition, or at least fail to assume pathogenic powers.

# Cyllin Palatinoids

are accordingly indicated as a direct and reliable preventive measure.

Cyllin Inhalant as an auxiliary agent may be relied upon to supplement the action of Cyllin Palatinoids in the respiratory tubes, more especially the naso-pharynx, pharynx, and upper larynx. To be used pure in special Inhalator.

See Pamphlet entitled "STANDARD CHEMICAL DISINFECTANTS." Copies, together with working Samples, sent gratis and postage paid on applying to

Jeyes' Sanitary Compounds Co., Ltd., 64 Cannon Street, London, E.C.

# The New Dietetic Preparation.

OVALTINE is a dietetic preparation—in granular powder form—of high therapeutic value, made of Malt Extract, Fresh Eggs, Milk, and Converted Cocoa, and containing Active Lecithin.

Very Palatable and acceptable to the most delicate stomach.

Simple to prepare.

The best substitute for Tea, Coffee, &c., and the only preparation of this kind containing Organic Phosphorus (Lecithin).

A powerful Digestive Agent and a Nervine Tonic of the highest order.

# OVALTINE

is the remedy par excellence in Convalescence, Neurasthenia, Faulty Digestion, Malnutrition, Brain Fag, Over Study, and Exhaustion. Readily assimilated and particularly adapted for the over-feeding of the Tuberculous. Suitable for infants, youths, adults, and the aged.

OVALTINE is packed in 42 oz., 9 oz. and 18 oz. tins. LITERATURE AND SAMPLE FREE TO MEDICAL MEN.

A. WANDER, Ph.D., Manufacturing Chemist, 1 Leonard St., City Rd., LONDON, E.C.

# TABLOID'BRAND HYPODERMIC PRODUCTS

'TABLOID' Hypodermic Products present the stated quantity of drug in its fullest activity and remain unaltered for many years in all climates.

They ensure accuracy of dosage and the use of reliable drugs in hypodermic medication.

They dissolve instantly, yielding solutions free from phenol, salicylic acid, or other preservative.

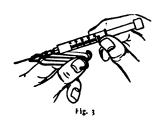

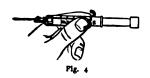

If the B. W. & Co. All-Glass Aseptic Hypodermic Syringe be employed, the required solution may be made in the barrel of the Syringe, as illustrated in Figs. 1 ana 2. Solution takes place rapidly and without danger of contamination.

Figs. 3, 4 and 5 show method of attaching and using the 'Tabloid'

## Valentine's Meat-Juice

Where a Powerful, Energetic, Non-Irritating, Rapid Blood-Building Nutrient is required, in a Concentrated Form, Easily Administered and Readily Tolerated by the youngest child, when all other forms of food fail, Valentine's Meat-Juice is recommended by eminent medical authorities and extensively used in Hospitals devoted to the treatment of

#### Diseases of Children.

Thos. N. Vincent, M. D., Visiting Physician St. Ann's Infant Asylum, Washington, D. C.: "I have used Valentine's Meat-Juice in St. Ann's Infant Asylum, in the treatment of cases of Diarrhoea, incident to Teething in infants of delicate constitutions, and find it in every way satisfactory. It is easily assimilated, attended with no untoward symptoms and agrees in cases where other foods fail and when milk, prepared in any way used at present, also failed. I can testify also to its usefulness as a nutrient in Scarlet Fever and Measles."

H. H. Powell, M. D., Professor of Obstetrics and Diseases of Children, Western Reserve University, Cleveland, Ohio: "If I were asked in what class of cases Valentine's Meat-Juice has proved of most value in my hands, I should say Cholera Infantum and the Dysenteries of Children. Nutritious and stimulating, it is so agreeable to the taste as not to be refused by any Infant, however sick, and is so entirely assimilated as to leave nothing to irritate the lower bowels."

Dr. Raphael Raimondi, Consulting Physician to the Montmartre Nurseries, Paris, France: "I use Valentine's Meat-Juice with Nurslings eighteen months to two years old. These very weak Babies derive great benefit from the use of this tonic preparation. I give it to Debilitated Infants, after they are eighteen months old, in doses of one teaspoonful in thirty gramms of boiled water twice a day, and to be continued for a month."

Physicians are invited to send for brochures containing clinical reports.

For Sale by European and American Chemists and Druggists.

#### Notes and COMMENTS.

Ventilation at the

MR. JUSTICE DARLING the other day corrected a barrister who spoke of the "New Bailey," pointing out that, Old Bailey. although a fresh and palatial building had taken the place of the old and

dismal Court where the last scene of so many sordid tragedies was enacted, historical continuity required that the place should still be known as the "Old Bailey." Without arguing the propriety of either designation, as to which much might be said, it seems that the architect and the City Committee responsible for the magnificent buildings, decided to keep to one evil tradition of the old Court, namely, that of insufferable ventilation. True, a system was designed, but it was a lamentable failure, and now air is left to find its way in and out of the courts at its own sweet will, which is as capricious as that of a maiden in love. Attention has been drawn to the defect time and time again, and only last week Mr. Justice Jelf and an alderman sitting with him had to complain of the excessive draught. Mr. Muir, the Treasury Counsel, replied that he had spoken of it so frequently that he was ashamed to do so any more, and the Judge finally said that if the matter were not attended to he would have to adjourn the Court-a very strong step. Now, it cannot but strike one as a most curious comment on the attitude of the public mind to hygiene, that where the Corporation are prepared to spend, and do spend, an enormous sum of money in erecting an enduring monument to the wealth and magnificence of the City in the shape of a criminal court-and a court where most of the parties are of the lowest and dirtiest class-that they should consider the question of health, as represented by the properties of air, as a kind of annoying minor detail which can afford to look after itself. The City Fathers are evidently more in touch with the insalubrious habits of their forbears than with the light of modern science.

Medical Congress.

THE forthcoming International Con-The Budapest gress of Medicine is now well within the scheme of practical politics. The sixteenth meeting—for the organisa-tion has now attained that critical

age-will be held at the beautiful city of Budapest, the capital of Hungary, opening formally in the banqueting hall of the municipality on Sunday, August 29th, and closing on September 4th. From detailed notices that have reached our office, it looks as if those responsible for the success of the meeting have taken time by the forelock, and have already drawn up a full and complete plan of cam-paign. Their activity—it may be remarked in passing-forms an agreeable contrast with the happy-go-lucky methods experienced at sundry

other congresses of no very remote date. One of the common-sense arrangements now announced is the possibility of securing rooms from the present moment, either in hotels or in apartments, by paying certain fixed prices in advance. In this way it is possible for intending visitors to form a fairly accurate estimate of expenses, and they have the further advantage of being able to choose accommodation at various prices which are accurately set forth under classes A, B and C. A small sum (8) kroner) is payable as a kind of registration fee by members who secure accommodation beforehand.

An Ideal Country. BUDAPEST is a city of entrancing beauty and interest, and so is the surrounding country. No less than six excursions have been arranged, extending from two to ten days, and

costing from 150 to 457 crowns, a sum roughly equivalent to £7 10s. and £22 17s. No. 5 on the list lasts from September 4th to 13th, and allows five days in Constantinople. The excursionists may return vid Trieste by putting into Athens and Corfu (at about £20 extra cost). No. 6 extends to Bosnia, Herzegovina, Dalmatia and the Hungarian Littoral, and lasts twelve days. A reduction of about one-half is made by most, if not all, the railways between Great Britain and Budapest, on production of membership ticket. The chance thus afforded of seeing many interesting and historical places is probably unique in the history of medical men of the United Kingdom. Those who wish to obtain more detailed information will find a full account on page 431 of our present issue. They will also be able to gather any further particulars by writing to the Honorary General Secretary for Great Britain, Mr. D'Arcy Power, 10A Chandos Street, Cavendish Square, London, W.

Mailed Fists. NOVELTIES in surgery, as recorded in current journalism, are a constant source of joy. The latest we have seen hails from Berlin, and is embalmed in the Manchester Dis-

patch. Professor Hoëftmann lately showed two patients at the Surgical Congress, who, we are interested to learn, had both lost hands and feet, and would in the usual way be considered to be permanently disabled from carrying on their occupations, which were manual. But the Professor would not allow their misfortunes to ruin their usefulness to society. Consequently, he has had metal extremities made to fit on to the stumps, and has so designed them in one case that the patient, a locksmith, is able to carry on his handi-craft with perfect ease. It seems that his tools fit, "by a simple system requiring no outside aid," into the metal end of his stump, and he is able to follow his trade as well as ever. this be described, as in the headline, as a "miracle of surgery," though when we come to think of it, we are not sure if the manufacture of iron hands and mailed fists is part of surgery proper. In British text-books at least the question is severely tabooed. Without further inquiring how the patients get along without feet, we feel we may now safely conclude that surgery-like love-laughs at locksmiths.

Vet Another Accident.

ONE thing the Workmen's Compensation Act has done, if nothing else, is to enrich the meaning of English words, for the decisions of judges in

contested cases have gone from one her, till at present an "accident" point to another, till at present an appears to mean anything one does not like. At Marylebone County Court, last week, a workman claimed against the Kensington Borough Council on the ground that he was suffering from gangrene, the result of frost-bite. He stated that he was engaged on December 20th last for sixteen hours in distributing salt in the streets in connection with operations for clearing away snow. His feet became painful, and on consulting a doctor soon afterwards he was told he was suffering from frost-bite. Medical evidence from St. George's Hospital confirmed the fact, and his counsel contended that as the occurrence which gave rise to the injury was unintended and unexpected, and produced loss, it came within the meaning of the The Judge agreed with this view, and While granted the applicant his compensation. sympathising with the workman in this case, it is difficult in the extreme to see how a disease resulting from prolonged exposure to cold, and probably from the patient's previous bad health, can in any sense of the word be termed an accident. To hold such a view is to throw medical terminology and indeed the whole English tongue into the melting-

#### LEADING ARTICLES.

THE RESEARCH DEFENCE SOCIETY.—No. I.

THE publication in book form of certain selected articles and views by the Research Defence Society marks an important step in the collective defence of scientific medicine. The movement is still in its infancy, for the body in question was founded so recently as January 27th, 1908, but the small volume before us forms a complete vindication of the avowed objects of the Society, namely, "to make known the facts as to experiments on animals in this country, the immense importance to the welfare of mankind of such experiments, and the great saving of life and health directly attributable to them." (a) We propose to take a few salient points from some of these communications, with the view of showing the direct practical value to mankind of experimental research, as an assertion to the contrary is one of the stock weapons of the anti-vivisectionist. One of the most suggestive articles is one dealing with the experimental study of the action of drugs by Professor Cushny,

F.R.S., of University College, London. At the outset he quotes a remarkable instance of the failure of clinical methods to determine the precise action of a given drug. Digitalis was introduced by an English physician-Withering-and became widely used as a remedy. In 1860, however, seventy-five years after its introduction, a writer on therapeutics stated that digitalis slowed and weakened the heart, and should therefore be administered in aneurysm, apoplexy and acute fever. A few years later that drug was shown experimentally by Traube and Brunton to raise the blood-pressure to a marked extent, and its use was absolutely contraindicated in aneurysm and apoplexy, while in pneumonia and fevers it was restricted to cases in which the heart became Used in cases of pneumonia without affected. heart complications, digitalis would probably do more harm than good. The precise therapeutic value and appropriateness of this valuable remedy were ascertained solely by experimental methods. In a similar way an immense expansion of the resources of the therapeutist has taken place. As a matter of fact, a large number of new remedies. have been discovered quite accidentally in the course of investigations which have had no direct therapeutic object in view. Chloral furnishes a case in point. Chloral was found by Liebig in 1832, but was not used medicinally for thirty-six years, until Liebreich discovered its soporific action by experiments conducted for the investigation of a problem of purely scientific interest, namely, whether "a substance is broken up into its constituent parts before it is oxidised." Dr. Cushny remarks that no soporific has been introduced in the last forty years, except by means of animal experiment, and, further, that no local anæsthetic has been discovered by other methods. Let the opponents of experimental research try and realise the enormous amount of human suffering that has been daily averted by the introduction of cocaine, to take a single one of the long list of drugs included under the heading of local anæsthetics. A similar proposition can be put forth with regard to vascular dilators and vascular contractors, all of which owe their origin to experimentation. Among other substances similarly introduced may be mentioned lysol, apomorphine, ethyl chloride, and thyroid gland, Indeed, Dr. Cushny is able to mention only one drug of even mediocre importance that has been brought into use by other methods during the past forty years, "during which the experimental method has been so fruitful in valuable remedies. The exception is pilocarpine, which was introduced in 1874 from its being used in South America as a sudorific." Another convincing article is that by Mr. Louis Courtauld on the value of antitoxin in the treatment of diphtheria. There is hardly any one subject upon which the opponents of experiments upon the lower animals are more positive and vehement than that of the failure of antitoxin treatment to lessen the loss of life from diphtheria. As our readers know, the matter has to be carefully examined to eliminate the fallacies. The frequent assertion, for instance, that, on the whole, diphtheria has risen rather than fallen since the introduction of antitoxin, is fallacious by reason of the epidemic waves to which

<sup>(</sup>a) "Publications of the Research Defence Society, 1908-1909." Macmillan.

the disease is subject, the former separation of croup from diphtheria, the recognition of latent cases of diphtheria, the fact that the Registrar-General's mortality figures are the main source of information, and the modern possibility Where the case-mortality accurate diagnosis. is ascertained, together with an exact diagnosis, and the number of patients treated with antitoxin noted, a reduction in fatal cases, roughly speaking, of one-third has been recorded. In the Metropolitan Asylums Board hospitals the mortality fell from 28.5 per cent. in 1880-1890 to 8.3 in 1908, in New York from 36.7 in 1891 to 13 in 1899, and in Paris from 45 in 1893 to 14.5 in 1898. Positive results of this kind form an argument unanswerable by any logical process of reasoning. There is so much matter of interest in the rest of the Research Defence Society's little book that we propose referring to it in a second article at an early date. Meanwhile, the energetic Secretary, Mr. Stephen Paget, may be congratulated upon the fact that the membership of the Society now extends to the handsome total of 2,250 names.

### THE CAUSE OF POST-OPERATIVE TETANUS.

THE subject of post-operative tetanus has been brought prominently before the medical profession by two communications, one which was read before a medical society in Dublin by Dr. L. G. Gunn, and the other which appears in the British Medical Journal, by Dr. W. G. Richardson, of Newcastle-on-Tyne. Both writers were led to discuss the subject by the unfortunate fact that they had met, or had had their attention drawn to, cases of post-operative tetanus, and both writers make an earnest and important attempt to elucidate the mystery which always surrounds such cases. It is unfortunately the fashion to attribute post-operative tetanus to infection received from catgut. train of arguments which leads to such a belief is, at first sight, so rational that broken links are overlooked, and its acceptance has been so general that other possible explanations have shared a similar The writers mentioned are, therefore, especially to be commended, because they have not allowed their investigations to be hampered by pre-conceived ideas. Though neither of them are in a position at the end of their investigations to formulate definite conclusions, they both are able to Both recognise the bring forward suggestions. extreme difficulty of imagining that catgut can give rise to a small epidemic of cases in particular localities, while places outside these localities are entirely unaffected, although they receive catgut from the same general source and use practically identical methods of sterilisation. Dr. Gunn's investigations, made in a hospital in which three cases followed one another at short intervals, resulted in the finding of a water supply which might, or might not, be contaminated, and which certainly offered opportunities of contamination. Assuming that air-borne tetanus germs had reached it, it also offered a convenient mode of distribution. Dr. Richardson goes further afield for his explanation. In the first place, he calls attention to three points of considerable interest. The first point is that 90 per cent. of the operations in which postoperative tetanus occurred involved the peritoneal cavity. The second point is that there is a disease amongst sheep known as "louping-ill," whose similarity to tetanus is very marked. The late Professor Hamilton was the first to call attention to this disease in a paper entitled "The Alimentary Canal as a Source of Infection," and he suggests that "idiopathic tetanus" may be a disease produced by the same class of organism as that producing "louping-ill." Dr. Richardson's third point is that the geographical distribution of "loupingill," as defined by Professor Hamilton, and of the cases of post-operative tetanus which he has collected, is almost identical. In this connection, it is of importance to note the actual facts. Professor Hamilton speaks of the valley of the North Tyne as "one of the most severely-smitten areas" in the case of "louping-ill," and Dr. Richardson finds that of his twenty-one collected cases of tetanus eleven occurred in Northumberland. He therefore suggests that the disease which we call post-operative tetanus is not tetanus at all, but one of the sheep diseases; that it is not introduced by catgut; that the patient at the time of the operation is the host of the bacillus, and that we must look on cases of post-operative tetanus as cases of "idiopathic tetanus," accepting Professor Hamilton's suggestion that "idiopathic" is not "true" tetanus. The suggestions made by Drs. Gunn and Richardson are in a great sense speculative, and it is impossible to say whether it will be possible to substantiate the one or the other. However that may be, by drawing our attention away from a supposition which time and repetition has converted into a "fact," they have done a most praiseworthy and necessary work.

#### CURRENT TOPICS.

#### Infantile Mortality in Workhouses.

THE Minority Report of the Poor-law Commission drew public attention to the remarkable fact that the mortality among infants born in Poor-law institutions was two or three times as great as that among those born to the general population. Certainly this state of affairs called for investigation, as we have a right to assume that workhouses, even if not ideal nurseries, are at least maintained in a condition as sanitary as the homes of the poor. The Local Government Board have investigated the subject, and, in consequence, have just issued a Memorandum setting forth the facts they have elucidated. In the first place, considerable fault is found with the figures supplied to the Commission on the ground of inadequacy, and they deprecate the "definite and sweeping conclusions" of the Minority Commissioners based on these premisses. Still, the mortality is too high to be explained by merely inadequate figures, and the chief point on which the Board rely in their apologia is on the general type and character of the parents. The proportion of illegitimate births in workhouses is enormously high. The metropolitan workhouses give a proportion of 60 per cent., while that for the general population of London is 3.75 per cent. The wretched mothers, and hardly less wretched fathers, frequently suffering from syphilis, are hardly of

the type to produce healthy offspring, and when this consideration is taken into account, with the further fact that about half the children leave the institution within three weeks of birth, it is obvious that the excess of deaths falling within this period points rather to pre-natal conditions and physical debility or disease than to want of care during the first year. Now, of 312 children who died in metropolitan workhouses, no less than 112 died in the first week of life, a death-rate of 42.2 per thousand! In the second week the rate fell to 6.1 per cent., which is actually a trifle lower than that of infants born to the general population. These considerations, while pointing to a somewhat excessive zeal on the part of the Minority Commissioners, also teach the lesson that paternal culture -if one may use the expression-is of supreme importance in raising human stock.

418 THE MEDICAL PRESS.

Disease and History.

In a recently-published book by Mr. W. H. S. Jones and Dr. E. T. Withington, a most interesting argument is adduced to account for the contrast between the poor and mentally-feeble population of modern Greece and the virile, intellectual people who created the most wonderful literature, art and philosophy in the history of the world. The theory, in brief, is that malaria was introduced into the country and created such ravages that the population of the valleys and lowlying districts were not only decimated and held in numerical check, but that their ancient moral and physical energy were swept away. Such a theory would certainly account as nothing else would for the extraordinary change which has admittedly taken place, but, fascinating as it is, no particular weight must be assigned to it without some historical evidence in its favour. Naturally this is very difficult to procure, as the invasion of malaria would be insidious rather than dramatic, and, not being recognised clinically, would fail to catch the eye of writers. Mr. Jones and Mr. Withington have nevertheless made the most of the material at their disposal, and have presented a very plausible case for consideration. Such an innovation in the treatment of the facts of history was certain to find much criticism at the hands of the orthodox school of historians, to whom battles and political changes make up most of the substance of their science, and criticism has not been spared. Professor Ronald Ross has gallantly stepped into the arena, and in a letter to the Literary Supplement to the Times, he draws an interesting parallel between Greece (if the theory be true) and Mauritius, showing how that island, from being nearly a heaven on earth, was in 1865-7 turned by the introduction of malaria into a poor, sparsely-populated, unhealthy country. In Greece, as in Mauritius, the valleys would be the places to suffer, and the well-to-do would retire to the high lands to live, with the consequence that agriculture and trade would be paralysed. The argument would not affect large places like Italy, where the natural features are so widely varied, and where malaria would be chiefly confined to swampy districts, unlike Greece, which consists chiefly of mountain and valley. So many new lights have been admitted to shine into history in the last half-

century, that we trust this attempt of Mr. Jones and Dr. Withington will establish the right of pathology to count as a factor in the influences which make and mar empires.

#### Anti-Vivisectionist Falsehoods.

At the recent annual meeting of the supporters of the Meath Hosptal, Dublin, Sir John Moore, the senior visiting physician, gave an emphatic denial to a statement which had been circulated to the effect that vivisection has been practised at the hospital, and said that it was a deliberate and unfounded falsehood. It is a poor heart that never rejoices, and Mr. Stephen Coleridge has taken advantage of Sir John Moore's indignant denial of an antivivisectionist falsehood to write to the papers and point out how "in Dublin they seem to know well enough that the financial supporters of hospitals for the sick poor are drawn from the tenderhearted, sympathetic, deeply moral sections of the community, to whom vivisection is an immoral, disgusting, and degrading practice. They admit that the mere rumour that the Dublin hospitals are in some way associated with the odious thing is sufficient to check the flow of subscriptions; and they are fortunately untramelled by the august influences which, some of us deplore to observe, are in London being more and more extended to the patronage of vivisection." One would have thought that Mr. Coleridge would have been unwilling thus to draw public attention to the fact that a falsehood had been promulgated in support of the cause he advocates, and especially that he would not have tried to gain a trifling point by its aid. It may be a source of dissatisfaction to him to learn that, although at the time the falsehood was promulgated there was in Dublin a certain proportion of people which had never taken the trouble to probe the true inwardness of the antivivisection movement, and who gave it some supvivisection movement, and which gave it some supdiminished. The deliberate and uncalled-for attack on the Dublin hospitals drew attention to antivivisectionist methods, and the foundation of the Dublin branch of the Research Defence Society removed a cloud of misconception which had merely resulted from ignorance of the necessities and value of scientific research.

#### One Day in Seven.

In the rush and hurry of modern life, the twentieth-century man is apt to lose sight of the wisdom of the ancients with regard to the proper guidance of life. One of the soundest of these ancestral laws is that which devotes six days to labour and the seventh to rest, as set forth in the Hebraic Code. A good deal depends on the exact meaning attached to the definition of the word "rest," and it is clear that what is rest to one man may spell quite another thing to his neighbour. The sedentary man wants golf or something that gives him fresh air and exercise in keeping with his time of life, while the active man who works with body or brain requires rest in hammock or armchair or other lounging attitude in the best air obtainable. Apollo cannot always stretch the bow. nor can the most physically perfect of our men and women always live at high tension. Sooner

or later the busiest have the lesson brought home to them of the absolute need of a rhythmic change of occupation, and that one day of rest in seven is requisite to keep the human machinery in first-rate working order. If the bodily engine be not used sufficiently it rusts; if it be worked without cessation it wears out prematurely. Viewed in this light the week-end out of town for the wealthy, and the Saturday half-holiday and Sunday rest for the worker, are the wisest and best safeguards for the conservation of the national efficiency at its highest standard. Therefore, now and then idleness is not an unpardonable sin. Verbum sap.

#### The Medical Register for 1909.

THE appearance of the Medical Register for 1909 is an event of sufficient importance in the medical world to demand a passing notice in the columns of a professional journal. The accuracy of much of the information contained in its introductory pages renders this volume of value as a book of reference. The abstract of the Medical Acts from 1858 to 1905, for instance, should be useful at times to any and every medical practitioner. One point of permanent interest is the annual increment of numbers of medical men on the Register, which, of course, does not represent the total number of qualified men, as many of the latter have never taken the necessary steps to have their names placed upon the official Register of the General Medical Council. The number on the Register at the end of 1908 was 40,257, or an increase of 1,430 on the preceding year; these figures show an increase over the average of the last five years. and a much larger increase over that of the past quarter of a century. There is a formidable list of twenty-six corporate bodies entitled to grant registrable qualifications, a fact that may well give pause to the most ardent "one-portal" reformer when he realises the magnitude of the interests he is seeking to consolidate and unify. This year the size of the Register is slightly, but still appreciably, increased, a fact which is fully accounted for by the additional matter entailed by fresh names and more extended official information.

#### Camping-Out as a Curative Measure.

Many of the maladies of modern civilisation undoubtedly spring from lack of fresh air and regular exercise, with an intake of food and drink in excess of the bodily requirements. For all com-plaints of that class the "simple life"—as it is called -is not only a perfectly logical, but, as a rule, a successful method of treatment. In strenuous America-where it is rarely the fashion to do things by halves-camping-out has come into great vogue. The outfit of the camp for sleeping, cooking and other needs of elemental life have been reduced by the ingenious storekeeper to the level of a fine art. Should it be elected to travel along a river, the boat can be covered in at night, or, more commonly, a tent is pitched on shore. Sometimes the whole camp outfit is carried on mules or ponies. In any case, the life in the open, with its accompaniments of pure air, exercise, plain food and early hours, is calculated to bring a fresh lease of life to the jaded dweller in crowded towns. There is no particular reason why camping-out should not be extensively practised during the summer months in the United Kingdom. The cost of a plain tent outfit would in most instances be more than covered by the week's rent payable for cramped lodgings at any popular seaside resort in the holiday season. If that will-o'-the-wisp, a return to the simple life, be a desirable thing—and few medical men would argue to the contrary—then camping-out is surely one of the most logical, as it is the most available, of all our civilised essays in that direction. Those who have lived once on a camping-out expedition appear never to want a better holiday—a fact that speaks volumes in its favour.

#### PERSONAL.

THE KING has been graciously pleased to confer the new Territorial decoration on Surgeon-Lieut.-Colonel J. D. Lloyd, of Chirk, North Wales, who has been attached to the Shropshire Yeomanry for thirty years.

FIELD-MARSHAL LORD GRENFELL, P.C., G.C.B., will take the chair at a Festival Dinner in aid of the East London Hospital for Children, Shadwell, which will be held at the Ritz Hotel to-night.

THE LORD MAYOR OF LONDON will preside at the Festival Dinner of the Royal Hospital for Incurables, Putney Heath, on May 5th, at the Savoy Hotel.

THE Festival Dinner of the City of London Lyingin Hospital will be held at the Trocadero Restaurant on April 29th. The Hon. Rupert Guinness, C.M.G., M.P., will take the chair.

THE Government have granted £200 to Mr. Harry W. Cox, manufacturer of X-ray apparatus, on account of his sufferings through the use of Röntgen-ray, apparatus.

THE LORD MAYOR OF LONDON will preside at a Festival Dinner in aid of the funds of the City of London Hospital for Diseases of the Chest, to be held at the Trocadero Restaurant on May 6th.

DR. T. SHADICK HIGGINS has been appointed Assistant Medical Officer of Health for Birmingham, in the place of Dr. Buchan.

DR. THOMAS CRAIG STEVENSON, Medical Officer of the Education Committee of the Somerset County Council, has been appointed Superintendent of Statistics of the General Register Office, Somerset House.

DR. T. A. SELLAR, of Aberlour, was last week presented with a handsome motor-car, subscribed for by patients and friends, in recognition of his services as a medical practitioner and of the esteem in which he is held in the district.

At a meeting of Convocation of the Royal University of Ireland, Dr. Campbell was elected representative of Convocation on the Senate of the University by 272 votes, as against 94 votes cast for Dr. Magennis, of Dublin.

### A CLINICAL LECTURE

ON

#### RENAL CALCULUS.

By ANDREW FULLERTON, M.D., F.R.C.S.,

Honorary Assistant Surgeon to the Poyal Victoria Hospital, Belfast, and to the Belfast Hospital for Sick Children.

(Concluded from page 398.)

PART II.

Diagnosis.-Although the symptoms which have been described will raise strong suspicions of a renal calculus, the patient must be examined by all the modern methods, to confirm or correct our diagnosis. It not unfrequently happens that a patient supposed to be suffering from a renal calculus is, in reality, the subject of gall-stones, duodenal ulcer, appendicitis, colitis, or some other complaint. The family and colitis, or some other complaint. The family and personal history of the patient may afford valuable assistance. The history of gout, or the passage of sand or gravel is of importance. The history of pain increased by exertion, the occurrence of typical attacks of colic, &c., will direct our attention to the urinary organs. A careful physical examination must now be made. It should be berne in mind that the painful kidney may actually be the sound one. Pressure on the affected organ may be associated with severe pain but on the other hand may afford no severe pain, but, on the other hand, may afford no assistance. I recently examined a patient in whom pressure on the affected kidney produced pain on the opposite side. Strong percussion in the lumbar region will in some instances produce severe pain, but it may as frequently fail. If retention or suppuration has occurred, the organ may be felt to be enlarged, and the stone or stones may even be palpable. In many cases, however, palpation and percussion will fail to enable us to come to a diagnosis. The urine must now be examined for blood, pus, casts, crystals, fragments of tumours, parasites, tubercle bacilli, and other abnormal constituents. I have already indicated how the cystoscope may be a valuable aid to diagnosis, and, in this connection, I might refer to the assistance which the ureteral catheter or probe coated with wax, or tipped with metal, may afford in some cases. Mr. Newman, of Glasgow, has devised an instrument for this purpose which he calls a resonator. [A short description of it is given in The MEDICAL PRESS AND CIRCULAR of May 6th, 1908]. Used in the ordinary way, the cystoscope is one of the most valuable means at our disposal for the diagnosis of kidney troubles. Pyuria and hæmaturia can be traced to their source with the greatest certainty, and the presence or absence of bladder complications can be accurately ascertained. When it is remembered that renal calculus may give rise to symptoms similar to an attack of acute cystitis, it will be evident that a careful inspection of the interior of the bladder ought not to be neglected. Again, before operating on a kidney which may, on exposure, prove to be so dis-organised as to require removal, it is, to say the least of it, comforting to know that there is a second kidney, and that it is capable of carrying on the renal functions. This can only be satisfactorily ascertained by previous cystoscopic examination, and catheterisation of the ureters, or by chromocystoscopy, that is, ascertaining the power of each kidney to excrete coloured substances, such as methylene blue, or sulphindigotate of soda. Cryoscopy, or the phlorizin test, may also be used alone or in addition to the colour tests, but it is advisable in all cases to use the ureteral catheter. Of course, the various segregators may be used, but one cannot inspect the interior of the bladder with these instruments, and one valuable means of diagnosis is lost. I have used the catheterising cystoscope in this way more than a hundred times without any serious result following, and I can recommend it to a careful operator as a safe, satisfactory, and expeditious method of ascertaining the condition of the kidneys.

The use of the X-rays is hardly less important, and a positive result is a great help to the surgeon. The presence of a shadow shaped like a calculus in the proper region is strong presumptive evidence of the presence of such, but is by no means conclusive, as other objects, such as calcareous lymphatic glands, phleboliths, fruit stones, fæcal material, atheromatous patches in arteries, &c., may give similar appearances. Mistakes of this kind are reduced to a minimum by the method, suggested by Mr. Hurry Fenwick, of passing an opaque ureteral bougie and noting the repassing an opaque ureteral bought and noting the least of the shadow or shadows to the line of the ureters. I have used ordinary ureteral catheters charged with fuse wire for this purpose, and have found that they show up exceedingly well in the photo. Of the various kinds of calculi usually found, it appears that the oxalates give the sharpest shadow. Next to these come those composed of uric acid or urates, while soft phosphatic stones are not so easily seen. This branch of radiography has recently been brought to such perfection that if the suspected stone is not visible in the X-ray photograph, some other cause will probably be found for the patient's symptoms. This work requires good apparatus and a skilful radiographer, and can only be satisfactorily

carried out in large centres.

Treatment.-Many attempts have been made to dissolve renal calculi, but though some evidence has been brought forward to prove that this may have been accomplished in a few isolated instances, most surgeons would consider it waste of time to trust to such a fortunate occurrence. At the same time, it is quite scientific to attempt to rectify any abnormality in the urine, such as excessive acidity or alkalinity, by appropriate remedies. If the urine is septic, it is a wise precaution to use urotropin dissolved in large quantities of water. This drug, besides acting as an antiseptic, is believed by some well-known urologists to exert a solvent action on calculi composed of urates or uric acid. Moreover, it is said to act beneficially in cases of phosphaturia. Large draughts of boiled water, or the various mineral waters recommended for this purpose, will be beneficial in diluting the urine and washing out small particles already formed. A question which it is a little difficult to answer is whether it is advisable to operate in all cases of ascertained renal calculi. It cannot be denied that an aseptic calculus may remain quiescent for years, or give rise to symptoms so infrequently as to cause the patient such slight inconvenience that he hesitates to subject himself to what must be admitted is a somewhat severe operation. Again, a small calculus may pass and leave the patient quite well. The patient must be given clearly to understand, however, that a calculus which is to-day aseptic may at any time become a source of danger, not only to the affected kidney, but also to the life of the patient, by the advent of sepsis, or by becoming impacted in the ureter. Besides, one cannot say with certainty, how much damage and degeneration may be occurring to the life of the patient. in a kidney the seat of even a small aseptic calculus. In the hands of a capable and experienced surgeon the risks of operation are so slight, that it is advisable to remove a calculus known to be present, if there is

no contraindication to the operation on other grounds, and this ought to be done when the patient is in the most favourable condition to undergo the ordeal, rather than at a time of great stress, when it has become a source of danger to him. It is quite likely that the patient, or his medical attendant, may not consent to this being done, and the operating surgeon must then content himself with pointing out the risks which the patient runs of a serious hæmorrhage, the onset of sepsis, or the occurrence of hydro- or pyonephrosis. Another class of cases will require consideration, those in which the operation will be of the nature of an exploration. We have all operated for renal pain or hæmorrhage or persistent pyuria, and have failed to find the expected stone. The risks of this unsatisfactory ending must be explained to the patient, so that no undeserved blame may be laid at the door of the surgeon, who has presumably done his best for his patient. If some other condition is found and relieved, the operation has been justified; if not, no great harm has been done. I can call to mind several cases of painless hæmaturia which were cured by the operation, though no lesion was discovered. With the aid of the X-rays such fruitless operations will become much less frequent in the future.

In contradistinction to the class of cases just discussed, there is a class in which operation is imperative—that in which anuria has occurred. If complete anuria is present, the patient will probably die if not relieved by operation. The anuria may be due to both ureters being blocked, and in this case, no time must be lost to free at least one kidney, taking care to select for attack the more efficient of the two, if it is possible to determine that point. If not, I see no reason why both kidneys should not be operated on, if the one first inspected seems incapable of carrying on the renal functions. Even an incision into the kidney will permit the escape of the pent-up urine, and save the patient's life. In cases of reflex anuria in which one kidney contains a stone, or in which a stone in the other kidney is not causing the obstruction, an attack must be made upon the side of the obstruction. This may be very difficult to determine. The previous history, the appearance of the ureteral meatus, and careful physical examination of the patient, may help to decide the point, but in any case, something must be done, and it is safer to explore both kidneys than to allow the patient to die while trying to make up one's mind which side to attack. It will also be necessary to operate in cases of acute septic infection occurring in the calculous kidney. At least an incision must be made into the affected kidney, and the sound one thus saved if possible. With the cystoscope, the proper side to attack can be determined with absolute certainty. Further proceedings may be decided on at a later date, when the severity of the attack has passed off, and the patient is able to stand the shock of a more prolonged operation. The presence of a calculus completely obstructing the ureter is an indication for immediate interference, first, to obviate the risks of serious, if not irreparable damage to the affected organ, and, secondly to obviate the supervention of sepsis and the conversion of a hydronephrosis into a pyonephrosis. In pyonephritis, operation must be undertaken without delay. In cases of severe hæmorrhage, operation is indicated before the patient is anæmic and exhausted by repeated attacks. Recurring attacks of severe pain will lead most patients to seek relief by any means, and it is not difficult to persuade a patient who has suffered the agonies of frequently repeated attacks of renal colic to submit to operation. Taking everything into consideration, therefore, it may be stated that a patient with a renal calculus is not in a safe condition, and that there are certain complications, such as anuria, obstruction, sepsis, hæmorrhage, and severe pain, that demand operative interference. Taken all round the mortality of operations for the relief of renal calculus does not, at the present day, exceed 5 per cent.

Operation.—The removal of a renal calculus having been decided on, it is now necessary to discuss, very shortly, the procedures which it is advisable to adopt. Most surgeons are now agreed that the lumbar incision is the best, for many reasons, to adopt. The kidney having been well exposed and brought out on to the loin, the pelvis may first be palpated, when, in many cases, the calculus will be found. This may be removed by incising the kidney, or cutting down directly on the stone through the pelvis, a method which has become more popular in recent years. In this way a good deal of damage to the kidney is avoided, and ecent results have shown that this wound heals quite kindly. It must be admitted, however, that it is more difficult to remove large stones in this way, and that there is a danger of overlooking stones in the kidney itself. For this reason, many surgeons prefer to incise the kidney through the convex border, right into the pelvis. In this way a very accurate examination, not only of the kidney, but also of the pelvis and calyces, can be made, and, if necessary, a catheter can be paseed into the bladder from the wound in the kidney, with, I think, greater ease, than through an opening in the pelvis. I prefer myself, so far as my present experience teaches me, to make my incision through the kidney itself. I have ascertained that the organ, even after very free incision, will perform its functions in a satisfactory way, as seen by examination with the catheterising cystoscope, even before the patient leaves the hospital, and the wound in the kidney seems to heal with the greatest rapidity. Clean-cut incisions into the kidney may be sutured with catgut, but wounds lacerated and contused by dragging a large calculus through, should be left at least partially open, any hæmorrhage being arrested before the kidney is replaced. If no stone has been discovered by the means already adopted, the ureter should be palpated as far towards the bladder as possible, the wound being enlarged, if necessary. If a stone is found far down the ureter it may be cut down upon in situ, or, preferably, it may be pushed up into the pelvis of the kidney, and so removed. In all cases, the patency of the ureter should be ensured by the passage of a long bougie or ureteral catheter. In this way, as in the case I mentioned earlier in this lecture, a stone may be dis-lodged, and an abortive operation converted into a highly successful one. If the stone is pushed into the bladder, it may be removed by the evacuator, or by crushing. In one of my cases it was passed by the urethra, after what appeared to have been an unsuccessful operation. A stone far down, beyond reach through the lumbar incision, may require removal through an incision similar to that used for ligature of the common or external iliac arteries. If projecting into the bladder, it will require removal through that viscus. Incisions into the ureters may, in accessible situations, be sutured, if the ureter is healthy, care being taken not to unduly narrow the tube. If inaccessible, or if the ureter is not healthy, they must be freely drained. In a few rare cases, it may be necessary to remove the kidney. In one of my cases, the stone had ulcerated almost through the ureter at its upper part, and there were numerous small abscesses in the thinned cortex of a pyonephrotic kidney, so that I was obliged to remove the organ. A good deal will depend on the condition of the kidney as regards the amount and character of the parenchyma left, and upon the efficiency of the other kidney. If the organ is extensively disorganised, it will only prove a source of danger, and ought to be removed, if the other kidney has been found to be efficient. If there is any doubt on the latter point, palliative measures must be adopted. After incision and drainage, it is surprising how much recovery may take place, and the individual experience of the operator will guide him as to how far to trust to conservative measures. If it becomes necessary to perform secondary nephrectomy, the difficulties are much increased by the scar tissue which will have resulted from the former operation.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by William Alexander, M.D., F.R.C.S., Hon. Surgeon, Boyal Southern Hospital, Liverpool; Lecturer on Clinical Surgery, Liverpool University. Subject: "On the Direct or Indirect Effects of Surgery or Surgical Lesions on Mental or Nerve Disturbances."

#### ORIGINAL PAPERS.

#### NOTES ON CASES. (a)

By T. CARWARDINE, M.S.,

Surgeon, Bristol Boyal Infirmary,

GALL-STONES IN GALL-BLADER, CYSTIC DUCT, COMMON DUCT, AND HEPATIC DUCTS, IN A GIRL OF SEVENTEEN.

This case is noteworthy from the youthful age of the patient, and the extent of involvement of the biliary apparatus.

She had indigestion two years previously, independent of food. Three months ago she had pain across the stomach and back, chiefly on the left side, and jaundice appeared when the pain ceased. A short time ago she had return of severe pain beginning and ceasing suddenly, lasting several days, and followed by jaundice. Thus she had two attacks of pain recently, in the first of which the urine was dark and the motion light.

When admitted she had a little jaundice and

no other symptoms.

At the operation there were adhesions about the gall-bladder, which was surrounded by jellylike lymph. (Fig. 1.) The liver was large and congested; and the gall-bladder, of yellowish colour, contained a milky fluid, stones and sand. On exposure of the ducts they were all found to be hard from contained stones. An incision was made into the common duct, where there was a large stone, and it was extended up into the cystic and common hepatic ducts, which were full of stones and grit. After these were cleared out more débris were found in the right and left hepatic ducts, which were also cleared. The pancreas was hard. Adequate drainage was provided, and the patient made a perfect recovery, leaving three weeks after operation.

STONE IN COMMON BILE DUCT WEIGHING 11 0Z., AND MEASURING 31 INCHES LONG AND 4 INCHES IN CIRCUMFERENCE.

This is an example of an enormous gall-stone removed from the common duct during life; although there is recorded an example of a larger stone, which weighed nearly  $3\frac{1}{2}$  oz., removed from a patient after death. In the latter case there is evidence that bile passed into the duodenum, for it is recorded that fluid bile surrounded the stone; and in my case, although the stone was so large, and its lower end fitted like a ballvalve into the dilated ampulla of Vater, the patient was not deeply jaundiced.

She was a woman, æt. 64, who had been subject to bilious colic for 37 years, and on two occasions gall-stones had been found in the stools. She was admitted a week after a bad attack of colic with rigors and sickness; the jaundice cleared up but again increased, and a hard resistant mass could be felt below the right hypochondrium, below which the lower border of the liver could be felt some few inches.

(a) Shown at the meeting of the Bath and Bristol Branch of the British Medical Association, October 28th.

When the abdomen was opened a very hard mass presented itself in the common duct, which gave a ringing sound when percussed with a pair of forceps. The gall-bladder was very small, and contained a solitary calculus surrounded by a little turbid fluid, and the cystic duct was occluded. (Fig. 2.) The large stone in the common duct was removed by extending the incision until it could be delivered. The finger was then passed into the much-dilated hepatic ducts above and the duodenum below. The wound in the common duct was sutured in part, and drainage provided. At first she was troubled with some sickness, and was reported to have had a kind of fit on four occasions during the first eighteen hours, each fit lasting from two to seven minutes—the jaw was fixed, the hands twitching, the eyes staring, there was no response to questions, and no change of colour. The patient made a satisfactory recovery, without pyrexia, and she is now well.

PANCREATIC CYST IN A BOY, AGED SEVEN.

The patient was a thin boy, who fell off his bicycle and struck the abdomen against the handle bar. He was seen two hours afterwards. when a slight contusion over the left hypochondrium was observed, and he complained of abdominal pain and tenderness in the epigastrium. There was little shock and no rigidity of the abdomen. The pain continued next day, and every ten or fifteen minutes there were severe colicky exacerbations. For the three days following the accident his temperature was 100 deg. to 101 deg., and he was frequently sick.

Five days after the accident a rapidly increasing swelling could be felt in the epigastrium, and the lower edge was clearly defined at first. Later the pain and swelling increased till the latter reached to three inches below the umbilicus, and occupied the whole of the right side of the abdomen, and the patient lost flesh considerably. Three weeks after the accident he had vomiting with a considerable increase in the size of the swelling. A month after the accident, I operated in the right semilunar line, when about three pints of clear yellowish fluid were withdrawn from a cyst, the wall of which was about one-eighth inch

thick and friable. (Fig. 3.)

The fluid was tested by Dr. Walker Hall, who gave the following report:—

S.G.—1008; alkaline.

Albumin—5 parts per 1,000 Esbach. Fat-Large traces in ether extract.

Deposit—Numerous cells containing fat droplets. Small amount of pigment, cholesterin and calcium crystals.

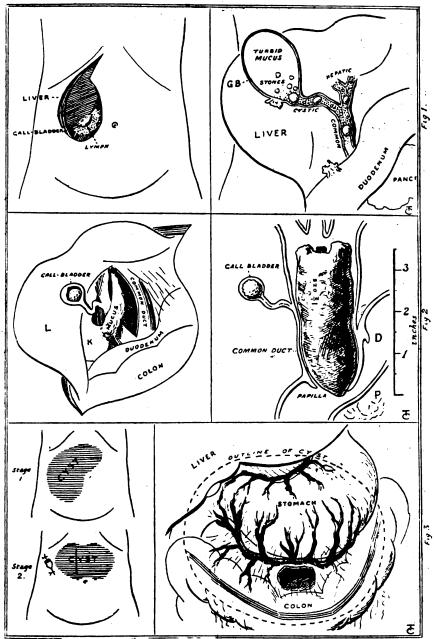

Digestive Action.—After forty-eight hours there is distinct evidence of the digestion of protein. (Trypsin therefore present.)

Reducing Substance .-- There is present a reducing substance which is not sugar.

After the operation very little more fluid escaped. and four days afterwards a swelling appeared in the epigastrium, rapidly increasing in size, and pushing the original drainage-tube downwards and outwards in the right loin. The colicky pains returned and the patient looked much worse. A second operation was, therefore, performed, six days after the first, through the right rectus muscle. The stomach was immediately below the incision, and adhesions to the parietes were separated. An opening through the gastro-

colic omentum revealed a tense cyst, from which about one and a half pints of fluid, with some coagulated serum, escaped. The discharge was continuous and profuse; caused considerable rritation of the skin, as if from digestion; and patient is now perfectly well, a year after the operation.

This case is a well-marked example of false pancreatic cyst described by Mr. Jordan Lloyd in 1892, resulting from injuries to the pancreas,

By permission of the Bristol Medico-Chirurgical Journal.]

Fig. 1.—Gall-stones in gall-bladder, common duct, etc.

Fig. 2.—Stone in common duct, weighing 11 oz.

Fig. 3.—Pancreatic cyst in a boy, 7 years of age.

the patient continued to waste. The cavity was, therefore, washed out with weak adrenalin solution, and the patient was fed with raw and cooked sweetbread. After ten days the discharge rapidly diminished, the wound soon healed, and the from the pancreas in the retro-peritoneal region,

and it bears out the contention that the lesser peritoneal cavity tends to be involved. Such cysts have occurred between the ages of thirteen months and seventy-six years, and as they arise they are covered by three layers of peritoneum. In the case here recorded there is distinct evidence that the cyst first occupied the lesser peritoneal sac, and then involved the right loin through the foramen of Winslow. After the first operation the foramen of Winslow must have become closed, leaving a retention cyst in the lesser sac of peritoneum, which required subsequent drainage. This view is confirmed by the fact that Albert saw a bulging of such a cyst through the foramen of Winslow. The mortality of the recorded cases has been about 10 per cent.; and it will be interesting to observe whether my patient develops diabetes in the future.

## ORAL BACTERIA AND ACQUIRED IMMUNITY TO DISEASE.

By J. SIM WALLACE, M.D., D.Sc.

Those bacteriologists who have devoted attention to the mouth have been impressed by the fact that it seems to be remarkably well adapted for the development of micro-organisms. Thus the late Prof. W. D. Miller says:—"If we compare the life conditions of bacteria... with the conditions prevailing in the mouth, it becomes evident that the oral cavity must be an excellent breeding-place for these organisms. It is equally clear that both their number and variety are continually being augmented by new germs which enter with the air, food and drink."(a)

The fact that the mouth presents such excellent opportunities for the proliferation even of pathogenic micro-organisms has naturally been looked upon with a certain amount of alarm, for its position at the commencement of the alimentary canal seemed to signal it out as the very cavity of the body which should be kept most scrupulously aseptic. Yet it has been conclusively proved: (1) That even a healthy mouth is never free from micro-organisms; (2) that there are no secretions of the mouth which have any appreciable antiseptic or bactericidal effect; (3) that the cleansing of the buccal cavity results from the detergent action of food, drink and saliva; and (4) that the natural cleansing of the buccal cavity (or the removal of the bacteria and their products) is practically invariably accomplished by swallowing, or removing the bacteria and their products into the stomach. This all seems very dreadful and dangerous, but, on the other hand, we know, as a matter of fact, that, notwithstanding these conditions, disease does not normally supervene. The tissues of the mouth are particularly well able to resist the invasion of micro-organisms, and the stomach has the power to digest and kill the great majority of the bacteria which enter it, so that even although minute numbers of bacteria do gain entrance, disease does not supervene, because the tissues and the blood have a certain power of resisting the invasion of pathogenic micro-organisms. Disease only supervenes when the invading parasites overcome the natural defensive arrangements of the

"The first line of defence of the body resides, in all probability, in the epithelial tissues which oppose the entrance of infective agents into the body." "It clearly must be a local power residing in the epithelial cells themselves, or on the fixed cells on which they are situated, rather than any general condition, such as the presence of opsonins in the blood."(a) It is a somewhat significant fact that the tissues of the mouth are the most resistant to the invasion of micro-organisms. Even a severe injury—e.g., the extraction of a tooth, which, indeed, is little less than a compound fracture, is very rarely followed by the invasion of pathogenic micro-organisms beyond the seat of injury. The walls of the stomach may not be so resistant to micro-organisms, but the stomach has the special power of digesting the bacteria, so that invasion through the stomach or alimentary canal seldom takes place, and even though some few bacteria should escape being digested, they would but rarely, in a state of health, at least, induce disease, because the tissues are not nearly so likely to be affected by small doses as by large ones.

Now, without going into further detail, I think the above facts indicate that the entrance of disease via the mouth is very well combated in a state of Yet, when disease does supervene, it undoubtedly does so in many cases by way of the mouth and alimentary canal. This may in some cases result from a specially large or virulent dose of pathogenic micro-organisms, but more generally it may be supposed to result from diminished resisting power of the body resulting from injury, cold, starvation or irritants, which diminish the local resisting powers. A question naturally arises, however. Do the bacteria and their products which are normally swallowed produce any further immunity to the diseases which might, and occasionally do, supervene when the natural resistive powers are temporarily lowered from any cause? We know that the injection of vaccines under certain conditions renders the blood more immune to corresponding diseases. We know also that a similar immunity can be gained by swallowing the vaccines.(b) We are therefore led to believe that the bacteria and their products which are produced in the mouth may tend to establish a similar im-munity under normal and healthy conditions, provided the dose be not unduly large.

If this be so, it would help to explain why ubiquitous pathogenic micro-organisms are, as a rule, innocuous, except in specially large doses or under exceptional conditions. It would also seem to explain why epidemic diseases claim so many victims, for if they are but rarely present there is little or no acquired immunity to the diseases. When we remember, too, how certain races are so severely attacked when a new disease is introduced into their land, we are probably justified in suspecting that those races had not acquired the immunisation which other races had to these diseases. It seems possible that a gradual immunisation even to epidemic diseases may at times result from the harbouring of some of the disease germs in the mouth, and consequently from swallowing a certain number of them together with their toxins. Now, although there is no doubt an inherent difference in the susceptibilities of different individuals to certain diseases, it is probable that the more marked differences result more especially from acquired immunisation. It would be difficult otherwise to explain why a disease such as measles should have been so very deadly when first introduced to the natives of the Polynesian Islands, and within a generation have ceased to be nearly so deadly in its effects. It is not sufficient to say that the susceptible were weeded out and that a relatively insusceptible race has evolved. A type is remarkably persistent, and the extinction

<sup>(</sup>a) "Micro-organisms of the Human Month," p.68.

of even large numbers in one generation will hardly produce any pronounced difference in any characteristic. It is much more probable that some individuals became immunised by having had the disease, others (the supposed insusceptibles) became immunised by way of the mouth, and their offspring became more or less immunised by way of the placenta. If vaccines can immunise by being injected or swallowed, there is no reason to doubt that the fœtus may be immunised through the placenta. I think we are justified in saying that, in addition to inherent immunity, we also derive immunity from the environment in which we live; in early life through the placenta, later through mother's milk, and lastly through the swallowing of their toxins.

Possibly toxins may be like some poisons: in small doses they may be beneficial, and the system may as it were become hardened to them.

It is not to be presumed that these facts or arguments would in any way justify us in introducing living pathogenic micro-organisms into the mouth even in minute quantities. For, although living micro-organisms seem to be absolutely necessary(a) in the alimentary canal, the introduction of pathogenic micro-organisms would be a very dangerous procedure in our present state of knowledge. Yet a hypothesis such as I indicate might help us to explain the immunity which some people seem to enjoy even when the mouth is in a most septic state. Mr. K. Goadby seems to believe in such an hypothesis; thus he says it is "possible that the property of natural immunity to many diseases is the expression of a gradually-developed tolerance to the attacks of micro-organisms evolved over long periods of time, and produced in a manner analogous to artificial immunisation.(b)

If we do not believe in a theory of acquired immunity such as I have tried to indicate, we would require to believe in each individual having a definite and hereditarily fixed amount of immunity, except in those cases where vaccination or disease had increased the natural amount. It would surely, however, be somewhat anomalous to conclude that the reaction to vaccines is not analogous to some natural process. Furthermore, it should be remembered that man is an animal having the power to adapt himself to almost any environment. It would again be anomalous to assume that in the matter of disease he was not capable of adaptation without the actual extermination of multitudes of his kind. At least, it seems to me more reasonable to conclude that he can gradually acquire immunity to ubiquitous diseases, and I would suggest that it is by means of the bacterial flora of the mouth, as indicated, that this comes about.

If the truth of the foregoing be granted, we see the extreme importance of a healthy, functional and physiologically clean mouth. It will readily be granted that a healthy mouth may be competent to deal with dangerous micro-organisms, but we shall not be so ready to admit this beneficent role when the mouth is dirty and fermenting after ill-chosen and ill-arranged meals, poisoned from carious cavities and suppurating gums, and functionless even in regard to the simple act of mastication and the insalivation of food in the mouth.

A NATIVE of Selukwe, Rhodesia, has been seized with sloeping sickness. It is believed that the disease was contracted at Quilimane, in Portuguese East Africa. It is declared that there is no danger of the disease spreading through infection.

#### OBSERVATIONS ON

#### THE PROVIDENT DISPENSARY.

BY GEORGE CRICHTON, M.A., M.D.

THE Provident Dispensary may be described in general terms as an Institution where people who are ill obtain medicine, they contributing to the cost by fixed weekly or monthly payments. In most instances these dispensaries have been started, and are maintained in part, by charitable contribu-That is to say, they are not completely nt. There is a group of provident distions. provident. pensaries called the Metropolitan Provident Medical Association, whose twenty branches have a membership of about 12,000 cards, including families, as well as single persons. They contributed about £5,200 last year, and the charitable public about £1,000, or nearly one-sixth of the whole. The management expenses amount to 11 per cent., for rent, caretakers, printing, etc. Only one branch in 1907 did not receive any addition from charitable funds, the average per card being 7s. 7d. The average of another branch is 5s. 7d. Members' payments vary from 1s. a quarter to 4d. and 6d. a month. The rules say there is a wage limit, but do not specify it. If 1 per cent, be a reasonable proportion of income for medical extendence that proportion of income for medical attendance, then ios, per annum would appear to be the proper contribution for a man earning £1 a week. It is quite evident that the average contribution, as above stated, is much too small, having regard to the means of the working classes. No statistics are given, and apparently the well-to-do workman is classed with the occasional out-of-work, and the donations given in the slump, not to particular cases. Where, for instance, the member's payment is 4d., enough should be contributed from voluntary charity to raise the whole to 6d. in that branch.

The total income being £6,200, the doctors receive £3,300, just above half, the management expenses and cost of medicines having first claim. Yet I suppose it is perhaps just as well to make up the medicine for every patient from a doctor's prescription. There is not a single item of information as to the payment received by the doctor per card or per case or per visit. From reports of other Dispensaries I gather that the payment the doctor gets is 3d. or  $8\frac{1}{2}$ d. per visit, or somewhere between these figures.

Can anyone tell me what is the minimum fee for a medical man to receive, so as neither to gain nor to lose? as if a shopkeeper were selling goods so as neither to gain nor lose—i.e., at cost price. I do not think it can be less than a shilling; including (or excluding?) medicine? More if the practitioner have the higher qualifications.

It is very difficult to get a clear and comprehensive view of the whole subject, but these two points seem clear: First, the contribution is too small from most (not all) of the provident members; second, the contribution and subscription combined should as nearly as possible afford a shilling per attendance to the medical officer. After thirty years the Metropolitan Provident Association, and those other Provident Dispensaries which appear mostly to work on the same lines, have a poor result to show. As to reform or improvements, of course, I understand that any increase must be small at first, also that gratis out-patient treatment at hospitals should absolutely cease.

Truly there is much to be done.

#### **OUT-PATIENT'S ROOM.**

METROPOLITAN HOSPITAL.

Retention of Urine.

By Dr. EARDLEY HOLLAND.

AMONGST those seen during the afternoon, the two following cases of retention of urine were of interest:—

The first was a single woman, æt. 36, who had been unable to pass urine since the early morning. The same thing had occurred once before, three weeks ago, and her doctor had had to use a catheter to relieve her. Except on these two occasions there had never been any trouble with the act of micturition. Questioned as to her menstrual history, she said she was perfectly regular, but that for the past six months the

periods had been profuse.

On examining the abdomen, a central, oval, fixed swelling was felt, reaching up to the umbilicus: it felt cystic and gave a fluid thrill on percussion. This was the bladder. Dr. Holland remarked that in all abdominal swellings arising from the pelvis in women, two possibilities should first be excluded, viz., pregnancy and distended bladder; if this simple rule were observed many mistakes would be avoided. The distended bladder was not always easy to diagnose from a fixed ovarian cyst by abdominal palpation alone. But Dr. Holland thought that the distended bladder has a peculiar feeling, which was easier to appreciate than to describe; it felt more superficial and closer under the skin of the abdominal wall than the ovarian cyst; this was especially the case when the fluid thrill was obtained. In an ovarian cyst a fluid thrill was only obtained with ease when the cyst was large, and distended the abdominal wall as a whole; in the case of the bladder, a thrill was obtained with ease in a swelling of moderate size which only distended a small area of the abdominal wall. If gentle pressure were made over a distended bladder, it always caused in the patient the painful sensation of a desire to micturate.

The golden rule in all such cases was obviously the passage of a catheter. This was done in the present case, and resulted in the passage of about four pints of urine. This was followed by the disappearance of the abdominal swelling, but deep down in the pelvis a hard, fixed, rounded tumour could be palpated. On bimanual examination, the cervix was found pushed forwards against the symphysis pubis by a hard, rounded, fixed swelling, which occupied the pelvis, and which was anatomically continuous with the cervix. Pregnancy being excluded, Dr. Holland said the case was certainly a large fibro-myoma of the uterus impacted in the pelvis, and causing retention of urine by pressure on the neck of the bladder. The patient was placed in the knee-elbow position, and with a finger in the rectum, forward pressure was made on the posterior surface of the tumour, which was easily pushed up out of the pelvis; a ringpessary was then inserted to temporarily keep the uterus from again falling backwards. The patient was advised to have the uterus removed as early as possible.

The second case was a married woman, æt. 32, who had had three children. The last period was three months ago, and she considered herself pregnant. For the past week she had had trouble in passing urine, the difficulty being chiefly in the commencement of the act; but since the previous night she had been absolutely unable to pass urine, and was now in

great pain.

Dr. Holland said that retention of urine; with a history of three months' amenorrhœa, was always a striking combination of two symptoms, and almost invariably meant incarceration of the retroflexed gravid uterus. The distended bladder reached the umbilicus, and was immediately relieved by the passage of a catheter. Bimanual examination showed the cervix pushed forwards against the symphysis by a softish, fixed swelling, which had well-defined borders, and

was anatomically continuous with the cervix. This was the enlarged pregnant uterus. Dr. Holland said that the next thing to do was to replace the uterus into its proper position and to keep it there. This was usually easy after the bladder had been emptied, and was often spontaneous. Pressure through the posterior fornix was unsuccessful in the present case, even in the knee-elbow position. Manipulation should not be violent or prolonged in these cases, for there was a risk of detaching a part of the ovum and causing abortion. The patient still being in the knee-elbow position, the cervix was seized with a volsellum, and the uterus drawn downwards away from the sacrum; at the same time the uterus was pressed forwards by a finger in the rectum. By this manœuvre the uterus was at once replaced. Dr. Holland said he had never known it fail, unless the uterus were bound down by strong adhesions; the whole point in it was drawing the uterus down away from the promontory of the sacrum, which often prevented it from passing forwards.

A ring pessary was then placed in the vagina to prevent a recurrence of the backward displacement of the uterus. This would be taken out in a month, by which time the uterus would have risen above the

promontory of the sacrum.

#### **OPERATING THEATRES.**

ST. THOMAS'S HOSPITAL

Obstruction from Carcinoma of Rectum.—Mr. Corner operated on a female, æt. 63, who had been ill for some weeks with symptoms of chronic or subacute obstruction. She had been worse for the past few days. On admission to the hospital she was found to be a very fat woman with distended belly; there was vomiting. Enemata were given without effect. The temperature was 99°, and the pulse 100. The abdomen was opened through mid-line below the umbilicus. There was a minimal amount of clear fluid, and the intestines were greatly distended and reddened; they were smooth and shiny, with no trace of fibrin about. An enormous sigmoid was brought out, ending in a small ring carcinoma at the upper end of the rectum. On attempting to bring the growth up, there was a squelch, and Mr. Corner said he thought he had torn the gut. Therefore, no more was done; a drain was stuffed into the pelvis. and colotomy performed. The patient made a good recovery.

RUPTURED SPLEEN.—The same surgeon operated on a boy, æt. 9, who had on the same morning fallen downstairs, injuring the left side. The patient had vomited once only. There was shock only on admission. Two hours afterwards the pulse had gone down from 98 to 86, but the boy looked bad, with very sunken face, and there was an area of flatness in the splenic region. Immediate operation was therefore decided upon. An incision was made through the left rectus. Dark blood showed up immediately on opening the transversalis fascia. The peritoneum was opened, and a quantity of blood escaped which, Mr. Corner pointed out, was fit usual character—that is to say, more recent red blood at the periphery and older dark blood in the flank. The spleen was found torn, and was removed. The progress of the case was good. The boy showed a certain amount of peritonism for 24 to 48 hours, but ultimately made a good recovery.

INTESTINAL OBSTRUCTION.—CARCINOMA OF SIGMOID.—The same surgeon operated on a female, æt. 49, who had been admitted with a history of chronic obstruction, with passage of mucus and blood, for two years on and off. She had suffered from subacute obstruction for a week. On admission to the hospital she was seen to be a fat woman, with distended belly. Nothing could be felt per rectum. At the operation the belly was opened through the left rectus. A small amount of clear fluid was found in the pelvis. A ring carcinoma of the signoid was discovered. Colotomy was performed. On the third day there were no untoward symptoms, and eventually the patient made a good recovery.

PADDINGTON GREEN CHILDREN'S HOSPITAL. Two Cases of Empyema.—Mr. Arthur Edmunds operated on two cases of empyema. The first was that of a boy, æt. about 6, with a history of six weeks' illness. After the periosteum had been lifted from a part of the seventh rib, which had been exposed by an incision a little posterior to the axillary line, a portion of the rib, about an inch long, was removed and sinus forceps inserted, when there was at once a gush of pus; a large amount having been evacuated, the cavity was thoroughly irrigated and a drainage

tube inserted. The second case was that of a boy, æt. about 6, who had a history of sudden dyspnæa which had occurred some four months previously. The peculiarity of the case was that there was some suspicion of a foreign body, perhaps a piece of match, having caused the symptoms and led to the formation of the abscess. The steps of the operation were similar to those employed in the previous case. The abscess those employed in the previous case. The abscess cavity was found to be small; Mr. Edmunds carefully examined it with his finger, but could detect no

case, and a drainage tube left in.

Mr. Edmunds said he always employed irrigation for the abscess cavity in these cases, although some surgeons thought there was a certain amount of danger in the procedure. He considered, however, that all risk was avoided if the irrigation was made with very low pressure; this was obtained by the vessel from which the solution flowed through the tube, being held very little above the level of the wound; by this means the liquid runs into the abscess cavity at a proceding in this way all very slight pressure. By proceeding in this way all cardiac danger was obviated.

#### TRANSACTIONS OF SOCIETIES.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

CLINICAL MEETING HELD APRIL 2ND, 1909.

Dr. SEYMOUR TAYLOR in the Chair.

THE following cases were shown and described by: Mr. PARDOE: A case of complete paralysis of the arm after excision of the elbow, following an accident. Scar dissected out, and the musculo-spiral nerve found to have been divided just above its bifurcation.

Anastomosis performed by end-to-end suture.

Dr. Frederick Palmer: Two cases of tabes dorsalis with unusual symptoms, and a case of habit spasm, in which irregular movements of the face, neck, head, and trunk muscles were markedly present.

Mr. N. BISHOP HARMAN: (1) A case of senile cataract with infantilism in a man, æt. 50, with the physique of a fat boy and penis of a boy of two years of age; well-formed scrotum, but no testes. (2) A case of chronic gouty conjunctivitis.

Mr. E. Archibald Smith: A girl, set. 18, with a

painless tumour of the tongue of ten years' duration,

probably a lymphangioma.

Mr. McAdam Eccles: A case of Charcot's ankle in a man, æt. 29, presenting symptoms of tabes dorsalis.

Skiagram showing much destruction of bony surfaces of tibia and astragalus.

Mr. CECIL H. LEAF: A case of excision of rectum for malignant disease by the abdomino-perineal method.

Dr. SEYMOUR TAYLOR: (1) A case of purpura. A heart from a patient who developed a loud bruit after sudden exertion, thought to be due to a torn aortic cusp, but found post-mortem to be due to an inflammatory deposit on the wall of the aorta just above the valve.

Dr. HALLS DALLY (for Dr. Abraham): (1) A case of dermatitis herpetiformis in a woman, æt. 39. (2) A case of bullous erythema in a boy, æt. 10. (3) A case of serpiginous syphilide in a woman, æt. 62. (4) A case of tricophyton endothrix on the scalp of a man, æt. 20, a contradiction to the statement of Dr. Sabouraud, of Paris, that the disease does not affect

adults.
Dr. E. C. Sparrow (for Dr. Saunders): (1) A case of myelo-cythæmia. (2) A case of Bazin's disease.

#### LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD APRIL 22ND, 1909

The President, Mr. T. H. BICKERTON, F.R.C.S., in the Chair.

#### Dr. A. A. BRADBURNE read a note on AMBLYOPIA EX ANOPSIA.

He dealt with that type found in conjunction with high degrees of refractive error. He considered the cause to be a cerebral defect, and based his treatment on that theory. He quoted one of his cases, a boy, at. 11, who had in six months' special training recovered vision from 5/50 to 5/5, or Jaeger I. He considered that want of success in treatment was due to the defect being a complex one, the visual act

depending on several centres.

Mr. NIMMO WALKER advocated the whole-time covering of the non-squinting eye until the vision of the squinting eye became equal to that of the other. This was possible in the majority of cases if taken early

Mr. R. C. Dun read a note on intussusception based on an analysis of 73 cases. He argued in favour of irrigation, followed, if necessary, by immediate section. Ether was always the anæsthetic used.

Dr. Hubert Armstrong discussed the paper.

Dr. Wilson read a paper on the SERUM DIAGNOSIS OF SYPHILIS.

Wassermann and Noguchi's tests were described, and their value contrasted. Using Wassermann, 23 results were positive out of 30 cases. Of 20 controls, 3 were positive, but in none of these could the possibility of syphilis be excluded. With Noguchi, 40 out of 52 cases syphilis be excluded. With Noguchi, 40 out of 52 cases were positive; also 3 out of 25 controls. Out of 30 cases submitted to both tests, 22 were positive with both, 4 negative with both; 2 were positive with Wassermann, and negative with Noguchi; 2 were negative with Wassermann, and positive with Noguchi. The opinion expressed was that Wassermann, although the more complicated of the two, was the more reliable.

Dr. Ernest Glynn referred to the fact that some cases of cancer growth gave the Wassermann reaction, and that a guinea-pig's heart was as suitable an antigen as syphilitic liver. The serum principle had been successfully employed in the diagnosis of typhoid and gonorrhœa.

#### CENTRAL MIDWIVES BOARD.

MEETING HELD THURSDAY, APRIL 22ND, 1909.

THE preliminary business was to elect a Chairman for the ensuing year. Dr. Champneys was unanimously voted to the chair, with a hearty vote of thanks for his past services.

Sir George Fordham was re-elected Hon. Treasurer,

and among the correspondence was a letter announcing his re-appointment to represent the County Councils Association on the Board for the period of three years ensuing April 1st. A letter from the Secretary of the Royal College of Surgeons of England reported that Mr. Cuthbert Hilton Golding-Bird, F.R.C.S., had been appointed to represent the College on the Board in place of Mr. J. Ward Cousins, F.R.C.S., retired.

In reply to a communication from the Secretaries of the Jubilee District Nursing Congress to be held in Liverpool, May 12th-14th, the Board decided to send two delegates, considering it advisable that in any important discussion on maternity work there should be some one present with recognised authority to speak on these matters. Miss Rosalind Paget and the Hon. Mrs. Chas. Egerton were nominated as delegates.

MEDICAL PRACTITIONERS "COVERING" MIDWIVES. In reply to a further communication from Dr. A. G. R.

Foulerton, County Medical Officer for Fast Sussex, as to medical practitioners "covering" midwives, it as to medical practitioners. Governing interviews, in was agreed that, subject to Dr. Foulerton's consent, the Board should forward the letters to the Privy Council, with the object of obtaining an opinion as to whether a certified midwife personally delivering a woman in childbirth is acting as a midwife where a medical practitioner has been engaged to attend the medical practitioner has been engaged to attend the case. In accordance with a wish expressed by the Chairman, Sir Wm. Sinclair had obtained from the heads of lying-in institutions in Prussia, Saxony, Russia, Norway, and Denmark particulars of the regulations applying to midwives in those countries which he now laid before the Board. It was agreed that a letter of thanks to each of these gentlemen be cant by the Secretary, enclosing a copy of the rules sent by the Secretary, enclosing a copy of the rules framed by the Board, and the recently issued report of its work since its constitution.

Letters were read from the Medical Secretary of the British Medical Association as to the supervision the British Medical Association as to the supervision of midwives approved for the purpose of undertaking the practical training of pupils. To the first of these the Secretary had replied stating the requirements of the Board before granting "Approval to sign Forms III. and IV., such approval only lasting one year; at the expiration of that time a further recommendation was required from the local supervising authority." Sir Wm. Sinclair thought more supervision was necessary. There was no evidence before the Board of evasion of rules by approved midwives. the Board of evasion of rules by approved midwives. It was agreed finally to reply that the Secretary's first letter embraced all the information required, but the Board would at any time be glad to be put in possession of any specific evasion of the rules which came to the knowledge of members of the British Medical Association.

#### CORRESPONDENCE.

#### FROM OUR SPECIAL CORRESPONDENTS ABROAD.

#### FRANCE,

Paris, April 25th, 1989.

TINEA CAPITITIS.

RADIOTHERAPY is, without doubt, the best treatment of tinea tonsurans. But the practitioner who lives far from a large town is obliged to prescribe a less modern treatment.

As a preliminary treatment the hair should be cut as close as possible and each patch of tinea treated by epilation.

Three times a week the whole scalp should be rubbed

Tincture of iodine, 1 oz.

Proof spirit, 4 oz.

And the other nights with the following unguent:— Pyrogallic acid, 15 gr.

Cade oil, 1 dr.

Vaseline, 5 dr. Each morning the head is washed with soap and hot water.

After a few days of this treatment, the parasite should be attacked.

The spots are washed with spirits of chloroform (5 per cent.), and finally with the above iodine solution. The diseased hairs are expelled by producing artificial folliculitis by means of pure croton oil applied with the end of a match enveloped with cotton or with a mitigated pencil:—

Croton oil, Cacao butter, } 1 dr.

The following day pure tincture of iodine is applied; after three days a wet dressing softens the crusts which can then be easily removed. The croton oil should be renewed every ten days. The treatment lasts at least nine or ten months.

Radiotherapy is, as has been said, the most effectual treatment of tinea tonsurans. The patch to be cured should be exposed, says M. Sabouraud, at a distance of six inches from the centre of the ampulla of Villard. During the first days of the treatment no apparent result is seen, but towards the seventh day a slight redness is observed. Depilation commences towards the fifteenth day and is soon complete.

The X-rays seem to affect the pilary papillæ, which progressively cease their function; the hair falls spontaneously charged with living parasites, for the X-rays do not kill the trichophyton. The treatment lasts three months.

General treatment is of but secondary importance. However, these patients being generally of lymphatic temperament, a series of tonics might be useful: codliver oil, syrup of iodide of iron, arsenic, sulphur baths, etc.

Tinea of the beard may be treated by epilation and application of tincture of iodine, or a modified form of that employed for tinea capititis.

Trychophyton of the nails is best treated by curettage and a permanent bath of iodine:

Iodide of potassium, 10 gr.

Iodine, 10 gr.
Water, 1 pint.
Each night a piece of absorbent cotton is steeped in this liquid and wound round the finger, which is then covered with an elastic fingerstall.

Or apply each night with a hair pencil:-

Acetone, 3 oz. Cade oil, 2 dr. Iodine, 15 gr. CHRONIC RHEUMATISM.

The local treatment of chronic rheumatism addressed both to the painful element and to the inflammatory phenomena of the articulations.

To relieve the acute or sub-acute pain so frequently observed, preparations with salicylate of methyl as a basis, are the most frequently employed:—

Chloroform, 5 dr. Salicylate of methyl, 5 dr.

Camphorated oil, 3 oz.

Or a liniment composed of equal parts of oil and

essence of winter green.

The German doctors recommend the application of compresses wet with a solution of phenic acid (2 or 3 per cent.).

Ointments composed of belladonna and cocaine are sometimes useful:

Hydrochl. of cocaine, 15 gr. Ext. of belladonna, 1 dr.

Vaseline, 5 dr.

Lanoline, 5 dr. in cases, M. Dieulafoy recommends a In certain cases, M. Dieulafoy recommends a poultice which Trousseau was wont to employ. This consists of bread-crumb moistened with water, placed

in a sand bath during three hours, after which it is thoroughly mixed with spirits of camphor until it has the consistence of putty; it is then spread on a cloth and coated with the following mixture:—

Camphor, 2 dr. Ext. of opium, 1 dr. Proof spirit, q.s.

The poultice is directly applied to the joint and covered with impermeable tissue, and left on for eight or ten days.

Against the inflammatory phenomena of the joints, tincture of iodine is utilised or the actual cautery, and sometimes a blister.

M. Teissier frequently uses dermatol, which has a vaso-constrictive action, useful against vascularisa-tion; it has also sedative properties:—
Subgallate of bismuth, 2 dr.

Vaseline, 1 oz.

Massage, says Dr. Dardel, of Aix-les-Bains, can render great service, not only as regards the general nutrition of the patient, but also for the nutrition of the muscles and the function of the articulation. However, it should be done with prudence, and only when all inflammation has ceased.

Electricity has been employed for a long time in the different forms of chronic rheumatism; faradic currents are especially useful to prevent muscular atrophy; while under the influence of continued currents the pain in the joint subsides and the periarticular contractions are favourably modified.

To apply the currents, the positive pole, under the form of a large electrode, is applied to the cervicodorsal or dorso-lumbar region, according to the seat of the rheumatism; the extremities of the patient are placed in a porcelain basin filled with warm salt water put in communication with the negative pole. Each day a stance of from 8 to 25 minutes with a current of from 8 to 25 milliamperes is practised. The negative pole may also be applied directly over the joint.

Baths have been used from time immemorial, but are specially indicated in the chronic form following acute rheumatism. They may be either simple or medicated (sulphur or arsenical baths). Vapour baths are sometimes very useful, while hot-air baths, according to the Tallerman-Sheffield system, are capable of

rendering great service.

It is impossible to say, concludes Dr. Dardel, to which of these methods preference should be given as the results obtained vary with the form of the rheumatism and the condition of the patients, consequently one has frequently to proceed gradually, trying one and another, until the treatment proper to that one case is discovered amongst the diverse methods.

In extreme cases, surgery may step in, but more particularly in rheumatism of the knees. Here resection has been followed by cessation of pain, and, although the patient recovers with an ankylosed joint, yet the function of the limb is much improved. In polyarthritis deformans, an operation (section of the tendons or aponeurosis) permitting straightening of the limb, can render service.

#### GERMANY. Berlin, April 25th, 1909.

At the Verein für Innere Medizin, Hr. Fleischmann gave the results of some experiences in the

INTRAVENOUS ADMINISTRATION OF STROPHANTHIN.

The experiments were carried out by a medical student, Hr. Wjasmansky. He said that the favourable reports made by some authors on the intravenous injection of strophanthin necessarily led others to make observations themselves. The preparation made use of was not Böhringer's, which was used by most authors, but the g-crystallised strophanthin Thoms (g-strophanthum crystallisatum Thoms). The advantage of the preparation was that it was a crystalline product, whilst all other strophanthin preparations were amorphous powders, which might vary more or less in their composition, especially as the mother drug—the strophanthin seeds—was a mixture of various seeds, whilst strophanthin was prepared from a well-characterised species, strophanthus gratus.

The results of the treatment were to some exteut brilliant, especially in cases of disturbance of compensation. In the shortest time—in a few minutes—a complete reversal might be brought about in the objective symptoms—frequency of pulse, dyspnœa—as well as in the subjective condition. If complete compensation in cardiac cases only occurred in the milder ones after a single injection, much less digitalis was required than usual—not more than a fourth or half. The cardiac complications of renal cases were also suitable for the treatment. Only moderate results appeared in the cardiac weakness of infectious diseases, also in the tachycardia and heart weakness of cachectics. A total of 52 injections of Thom's strophanthin were made on 30 patients. The dose was from 0.0003 to 0.0005 g., dissolved in 1 ccm. of water, and furnished in sterilised ampullæ. No case of sudden death, as observed by some authors, came under notice. It was to be noted that strophanthin was distinguished from digitoxin in that the latter only acted as a constrictor of the splanchnic vessels, whilst strophanthin acted on the whole of them.

Hr. Stadelmann had made experiments with uabain. By subcutaneous injection it was not so painful as digalen. The dose by intravenous injection was 3 decimilligrammes. The drug often acted like magic, but not in all cases. He believed that two or three cases of sudden death were to be laid at the door of uabain.

It appeared to be especially dangerous in arteriosclerosis of the coronary arteries. It hal to be used with great care.

Hr. Fleischmann did not know whether uabain was identical with strophanthin.

A discussion on the

TREATMENT OF INFECTIVE DISEASES OF WOUNDS

took place at the Basel Chemical Society, introduced by a paper by Prof. C. Haegler. He said that the idea of destroying germs by antiseptics was to be given up, once for all. Disinfection of inflamed tissues was impossible.

If he did not reject a moderate use of impossible. If he did not reject a moderate use of antiseptics, he could only recognise their usefulness in the direct destruction of bacteria. The bactericide serums had also proved deceptive. It was only from allied organisms that a useful serum could be obtained for our wound infection-carriers. The attempt to obtain serums for staphylococci and streptococci had failed even in the laboratory. Nothing could be done directly with the bacteria and their toxines. We must therefore try to raise the resisting power of the organism. Passive hyperæmia was not suitable for general practice, but he could recommend active hyperæmia (Preissnitz dressings, thermostats, etc.). If the affection could not be cut short, it could at least be limited. If the pain and febrile symptoms did not improve, surgical measures should not be delayed. Tension of the tissues demanded the scalpel, if extenwere to be avoided. All cavities should be plugged or drained; no "mêchen" resting position or suspension of the inflamed extremity. The kind of dressing and the technique were of importance. He was in favour of moist dressings. Prof. von Herff heartily agreed with what the speaker had said. He gave a special greeting to his warning not to injure the wall of granulation tissue. This was specially applicable to the treatment of puerperal fever, a true wound infection. Here a simple avanination might do harm fection. Here a simple examination might do harm, and still more scraping, which the speaker looked upon as a mistake. An infected wound could not be made germ-free at once, but gradually by the use of antiseptics to destroy the germs. But the behaviour of the various germs in the presence of the various antiseptics must be more attended to than it had been. Staphylococci bore carbolic acid the worst; pyocyaneus, acetate of alumina; diphtheria, phagedænic ulcers, above all hospital gangrene, salicylic acid in 2 per cent. of glycerine, or, still better, a 10 per cent. alcoholic solution; anærobic gas formers, peroxyde of hydrogen, and generally speaking oxydants and halogenes. Gonococci were also very susceptible to halo-genes—iodine—as was noticeable in the treatment of gonorrhoea in the female; silver might be made use of, but it was less effective than iodine. It was known of, but it was less enective than logune. It was known that this fungus was particularly susceptible to pernanganate of potash, applicable in treating children. Excitors of decomposition were readily attacked by aniodol, therapogen, and salol. The latter was excellent in a 1 per cent solution prepared from a 10 per cent alcoholic solution in offensive discharges of care lent in a 1 per cent. solution prepared from a 10 per cent. alcoholic solution in offensive discharges of carcinoma uteri. Aniodol had also proved very service-able in diphtheritic cystitis. Mercury was at once destructive for the monilia species, the fungus improperly called oddium, which frequently set up troublesome inflammations of the vulva.

He agreed with the unfavourable judgment of the reader of the paper regarding serum treatment. Col-

He agreed with the unfavourable judgment of the reader of the paper regarding serum treatment. Collargol was useless as regarded bacteria; possibly it bound up poisons by absorption, as the general condition of patients often improved after its use.

He had given up Bier's hyperæmia in mastitis, but he was friendly to dry tamponade with xeroform, and opposed to powder dressings, which only did harm. Commencing furuncles could be aborted by mopping with drops of 20 per cent. iodine, or liquefied carbolic acid, if applied at their first appearance. Furunculosis was best met by alcoholic washings, with spirit dressings, and the timely application of 2 per cent. tr. iodi. Instead of Peru balsam he employed tr. benzoin with great advantage.

Hr. Barth recommended tr. iodi in cases of infected

wounds and furunculosis.

## AUSTRIA. Vionna, April 25th, 1909.

DIABETES MELLITUS. Ar the Gesellschaft für Innere Medizin, Noorden gave the members a complete history of a case of diabetes which he had cured with a vegetable diet. The patient was a young man, set. 22, whose body weight had fallen to 45 kilogrammes, or 6 st. 4 lb. The urine contained large quantities of sugar, acetone, The urine contained large quantities of sugar, acetone, and acetic acid when admitted. The patient was first strictly limited to the usual diabetic diet, with 25 to 75 grammes of bread in the 24 hours—i.e., \(\frac{3}{4}\) of an ounce to 2.65 oz., which represented the total amount of carbohydrates. During this time he was passing 70 to 140 grammes of sugar in the 24 hours. The enormous amount of ammonia, 2.8 to 3.8 grammes per day, pointed to a large amount of salt in the urine. The analysis revealed about 20 grammes of ovphutyric soid analysis revealed about 20 grammes of oxybutyric acid and 2 to 3.8 grammes of acetone present. After two days' vegetable diet the sugar sank to 58 grammes, or nearly 2 oz., but the ammoniacal salts still stood at 3:3 grammes. After this the patient was given an oatmeal diet to increase the absorption of carbohydrates, as he was now in a serious condition from acid intoxication. The first day 250 grammes, or about half a pound, of the oatmeal preparation was administered, with wonderful restorative effects; the second day the quantity provided was less, but the analytical results were more unfavourable, as the sugar in the urine rose to 136 gremmes, or 4.6 oz., but the ammoniacal bodies were only 0.9 of a gramme, and the oxybutyric traces, the the orbit a gramme, and the oxputylic traces, the latter only being encouraging. Meat diet was given the next two days, the sugar still rising in the urine, but the acetone fell to 0.4 of a gramme. He was again put on vegetable diet till the amount of sugar per day fell to I gramme, with hardly a trace of acetone. With the exception of the two days on oatmeal, his diet was confined mostly to one free of carbohydrates up to this period. Again, 250 grammes of oatmeal per day were administered; the acetone could scarcely be detected; the vegetable diet was repeated and again followed by the oatmeal, the actione rising to 0.1 of a gramme. The same variety was followed for a few days till only a trace of sugar and acetone was found in the urine, the patient enjoying excellent health and

increasing in body weight. The sugar present in the blood when first admitted was 0.16, 0.15, and by the end of February was 0.18

was 0.15, and by the end of February was 0.18 per cent., the normal being 0.07 to 0.08.

Here we had hyperglycæmia with an abnormal retention or power of resistance in the kidney. After a short period the patient was again tried with carbohydrates, and 50 grammes of coarse bread given, but the sugar rose to 50 grammes a day in the urine. The patient from first to last, or from February to December 100 metabot to 100 metabot 100 metabo ber, 1908, was kept on a rigid diabetic diet, with the exception of these experimental tests, while he performed his daily employment, and increased in weight by 10 grammes. At the end of nine months a regular diet of 75 grammes of bread, half a litre of cream, and an apple were given in the 24 hours. More recently 300 grammes of potatoes have been added to that diet, and no trace of sugar or abnormal bodies are found in the urine. The patient is, therefore, using 60 grammes of carbohydrates without any trace of sugar in the urine.

#### REFLEX ANURIA.

Latzko, at the Gesellschaft der Ærzte, showed a that time there was severe pyelitis, with a large abscess, which was diagnosed at the time from a large amount of pus taken from the left ureter, while the right secreted normal urine. In July, 1908, the right secreted normal unine. In July, 1900, the patient again became ill with severe colic in the right side, or supposed healthy kidney, which was associated with persistent vomiting, anuria and headache. These attacks repeated themselves every 14 days, but the anuria continued in spite of catheterisation. Blocking of the ureter or hydronephrosis was suspected. Fourteen days previously he operated and found in the lower pole of the right kidney, embedded in the parenchyma, two calculi. The patient is now perfectly well since the operation.

#### FROM OUR SPECIAL CORRESPONDENTS AT HOME,

**BELFAST** 

ULSTER HOSPITAL FOR CHILDREN AND WOMEN.-The annual meeting of this hospital was held last week, Mr. G. W. Wolff, M.P., presiding. The medical staff report gave an account of increasing work in The medical every department, and increasing need for further accommodation. The hospital is worked on most economical lines, the average cost per patient per day being only as. 4d., while if patients, nursing staff, and servants are included, the average cost is only is. 63d. per head per day. Plans have been prepared for a new hospital, for which there is ample space, thanks to the wise forethought of those who moved the hospital to its present site about twenty years ago, and building will be proceeded with as soon as the necessary sum of £10,000 has been collected. Wolff has promised £1,000 on condition that no building is done till the whole sum is in hand, and other subscriptions have been given on the same understanding, amounting in all to over £5,000, so it is hoped that the whole amount will soon be subscribed. Dr. R. W. Leslie and Dr. J. D. Williamson, among other speakers, described the work of the hospital, and appealed for help.

SCARLATINA EPIDEMIC AT LURGAN.-A smart epidemic of scarlatina has broken out at Lurgan, co. Armagh, and is taxing the local accommodation to the utmost. At the last report there were about fifty children in the Lurgan Workhouse Hospital, and the small-pox hospital had to be utilised to accommodate some of them. The fever is of a pretty severe type, and there have been several fatal cases.

SALARY OF THE MEDICAL OFFICER OF HEALTH.-SALARY OF THE MEDICAL OFFICER OF HEALTH.—
Rather a flutter has been caused in municipal circles by a snub administered by the Local Government Board to the Public Health Committee of the Corporation. It will be remembered that on Dr. Whitaker's resignation of the post of Medical Officer of Health in 1906, a great effort was made to induce or force the Corporation to offer a sufficient salary to draw forth well-qualified candidates for the post, and in these efforts the Local Government the post, and in these efforts the Local Government Board joined. But in spite of all efforts, the Corporation did what had been predicted in these columns many months before; they appointed a general practitioner who had only lately resigned his seat on the Corporation, and who had no special qualifications for the protections for the control of the tions for the post. Now, when public indignation has died down, and attention is taken up with later scandals, the Public Health Committee proposes to raise its officer's salary by 500 per annum to \$800, but the Local Government Board has refused to sanction this, calling to mind its protests when the appointment was made. "The Board cannot lose sanction this, calling to mind its protests when the appointment was made. "The Board cannot lose sight," they say, "of the fact that the Corporation, after full deliberation, less than three years ago, assigned £600 as the remuneration for the work, and that Dr. Bailie accepted office on these terms, and, having regard to their usual practice of declining to consider proposals to increase salaries until five years have elapsed after the appointment, on the ground that the fixing of a low initial salary would tend to limit competition and discourage eligible candidates. they feel unable to concur in the present proposal of

the Corporation."

QUEEN'S UNIVERSITY: APPOINTMENT OF PROFESSORS AND LECTURERS.—A number of new appointments are about to be made in Queen's College in connection with the foundation of the new University. None of them are directly medical, but several of them are in the science school, and will more or less affect students of the preliminary medical subjects. They include a professorship of botany (till now united with zoology), and lectureships in physics, organic chemistry, bio-chemistry, and geology. The University Commissioners have been at work during the Easter recess, and it is still hoped that the new scheme of work will come into force next autumn, though some pessimistic persons predict that things cannot possibly be ready.

#### LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

#### DOCTORS AND MIDWIVES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—Will you allow me, in reply to Dr. S. J. Ross's letter in your issue of April 7th, to say I believe, from what I have heard, that there are places in the British Isles—"remote places," some would call them—where the skilled aid of a well-trained nurse would be welcomed by the medical man, who could not call upon a medical man or woman for assistance simply because there would be none in the district to whom he

could apply. I cannot give the names of those places,

but I daresay any medical agent could.

"I cannot," says the late President of the British
Gynæcological Society (Mr. W. D. Spanton, F.R.C.S.),
in his inaugural address, "leave this subject without
expressing my conviction that some of our best results are secured for us by those skilled nurses who know our ways, whose loyalty to the surgeon is unquestioned, and whose sole desire is to save the patient's life by devoted, unswerving attention and watchful-Such are as rare as they are invaluable, and I am sure you will agree with me in frank acknowledgment that much of our success as gynæcologists

is due to their assistance." Permit me to point out to your readers that I have been chiefly applying my remarks to ladies who are employed by missionary societies in those countries where women only are allowed to medically attend women and children, where there is no medical man or woman, and to those ladies who give their services as unpaid volunteers. The reports of all missionary societies utter the same cry—"We want medical men and women to fill posts where there is no medical man or woman." And this cry of need applies, not only to the component countries of the British Empire, but also to South America and other countries not under British sway. Let me quote some extracts from the quarterly magazine of the Zenana Medical Mission College and Hospital:—"Sir Patrick Manson, K.C.M.G., in his address at Livingston College, said:- 'Those who send out missionaries to work in foreign lands should lay to heart the importance of medical knowledge to a missionary. It is not fair to anyone to ask a man to go abroad to face unavoidable risks. Martyrdom is one thing, suicide is another, and murder—though he did not like to say the word—is a third; yet to send a man or woman abroad to work as a missionary in unhealthy climates, and not provide them with proper information as to how to prevent themselves being killed—he left his hearers to say what that would be. If the supporters of missionary institutions demanded that the missionaries sent out should have some instruction in caring for health, they would only be doing their duty.'

Here is what one traveller writes who has witnessed the needs we cannot adequately portray, and her words but express the wants of many places in other lands:—
"Just think—from Karachi to Bagdad, among the populous cities of the Persian Gulf, of the Tigris and Euphrates, throughout Arabia, throughout South and South-West Persia-not a medical man! From Bagdad to Teheran—almost the most populous district of Persia—not a missionary nor medical man! The great oasis of Ferghana, at a height of 7,000 ft., with 680 villages craving medical advice, never visited, scarcely mapped."

Here is another testimony: - "There was no medical man within 1,200 miles, and we were sometimes compelled to act, whether we knew or not, and we found a small smattering of information . . . was or the utmost advantage to us. I hope that all missionaries who go where there is no doctor at all will get as much knowledge as they possibly can."

"The profession" is said to be overcrowded. Why, when I started in practice about half-a-century ago, the same cry was all around me; I was told, "Oh! a small smattering of information . . . was of the

the same cry was all around me; I was told, "Oh! you'll starve; you'll have to give in; every place is occupied by medical men" (there were in those days no medical women).

It is not more crowded now than then, if we bear in mind the increase in the world's population, and the number of countries that have been opened up within the time to which I refer-viz., the early 'sixties. I write this to encourage those who are now young not to be daunted by any such cries, nor to be turned aside by any seemingly insurmountable barturned aside by any seemingly insurmountable parriers, but to temember the Latin poet's trenchant words, "Possunt quia posse videntur," which Paul and our missionaries would translate, "I can do all things through Christ, Who strengtheneth me."

I am, Sir, yours truly,

G. DE G. GRIFFITH.

London, S.W.

DENTISTS AND ANÆSTHESIA

To the Editor of THE MEDICAL PRESS AND CIRCULAY. SIR,—As a dentist with full qualifications on The Medical Register, I should like to add my voice to those who are pleading for justice to qualified dentists helding only the L.D.S. in the matter of the administration of anæsthetics; and I trust you will give us your powerful support. To prevent these men from giving "gas" or applying local anæsthetics will be to inflict undeserved hardship, not only upon them but also upon the public of the public and the public also will be them, but also upon the public. A clause could be easily inserted in the Bill specifically naming nitrous oxide as the agent that dentists might use; and giving them authority to employ obtundents of pain by injection into the gums. Some few years ago the injection into the gums. Some few years ago the General Medical Council being appealed to, declared that qualified dentists might legitimately administer "gas." It must be borne in mind that gas is not a deadly agent; and in the vast majority of cases can be given with perfect safety by the average qualified dental practitioner. Its safety lies in the fact that unlike chloroform, and similar agents, it does not in itself produce toxic effects, and accumulate in the blood. Gas, unless in very rare cases, can kill only by the deprivation of oxygen, and thus a deadly result can be brought about only by extremely prolonged inhalation. As soon as air is admitted the effects pass off; there is no poisonous dose to be got The number of deaths recorded from gas, including those occurring in the hands of totally unqualified men, does not amount to one in hundreds of thousands of cases. It would be unfair to dentists to deprive them of the privilege which they now enjoy; and unfair and unjust to the less wealthy classes of the public who cannot afford to pay the fee of a fully qualified anæsthetist for a simple operation like tooth extraction.

I am, Sir, yours truly, L.R.C.P., M.R.C.S., L.D.S.

London, W. April 24th, 1909.

#### SPECIAL ARTICLES.

#### .THE FORTHCOMING XVIIL INTERNATIONAL CONGRESS OF MEDICINE, BUDAPEST.

THE detailed arrangements for the Sixteenth International Congress of Medicine are now issued with a list of the Committees and a programme of the communications promised to the Sections. The meetings of the Congress will be held in the buildings of the former Polytechnic School Museum-korut 6/8, but the formal opening will take place in the banqueting hall of the Municipal Redoute at 11 a.m. on Sunday, August 29th, 1909. The closing ceremony will occur at the same place on September 4th, 1909, at 10 a.m. Six general sittings will be held during the Congress, at which addresses will be delivered by Prof. Baccelli, at which addresses will be delivered by Prof. Baccelli, of Rome; Dr. Bashford, of London; Prof. Kutner, of Berlin; Dr. Laveran, of Paris, and Mr. J. Loeb, of Berkeley, U.S.A. A journal will be issued daily, and there will be the usual secretarial offices and bureaus. Three new sub-sections have been formed, viz.: Orthopædics; Professional Hygiene; School Hygiene.

The arrangements for lodgings are dealt with below,

but the General Secretary calls attention to the difficulty of finding adequate accommodation for intending visitors to Budapest unless they give timely notice to "The Central Travelling Ticket Office iv Vigadó-ter I. Budapest, Hungary," and secure room by paying for them in advance. Certain concessions will be allowed by the railway companies to members attending the Congress. In Hungary the railways allow a reduction of 50 per cent. In France the management of the State railways and the East, North, and Orleans Companies also allow a 50 per cent. reduction to members provided with the proper vouchers; whilst in England the Great Eastern Railway grants a reduction to Congress members. Members of Congress who have paid their subscriptions will receive a circular about the end of May informing them of the method of claiming these reductions.

#### EXCURSIONS.

The Executive Committee offer six excursions for members after the Congress, each excursion being personally conducted and upon the ordinary inclusive terms, the first-class prices admitting of a single bedroom in hotels, whilst those who pay second-class will be lodged in couples. The first excursion costs 150 crowns first-class, and 135 crowns second-class (a crown is equivalent practically to a shilling). It includes a visit to Kolozsvar, the ancient capital of Transylvania, the Marosujvar salt mines, and the Rév. Pass. It leaves Budapest on September 4th and returns on September 7th

Excursion No. 2 is to the High Tatra, Dobsina Ice Cavern, and Postyen Baths, leaving Budapest on September 4th and returning September 9th. Price, 180 crowns first-class, 150 crowns second-class.

180 crowns first-class, 150 crowns second-class.

Excursion No. 3 is to Lake Balaton, which is one of the largest and most beautiful in Europe. Members leave Budapest on September 4th and return on the 6th. Price, 130 crowns first-class, 110 crowns second-class.

Excursion No. 4, the Lower Danube and Herkulesfürdő, leaving September 4th and returning September 8th. Fare, 185 crowns first-class, and 155 crowns second-class.

Excursion No. 5, Constantinople, leaving Budapest September 4th and returning September 13th. Price, 475 crowns first-class and 375 crowns second-class. This excursion requires passports visted at the Turkish and Roumanian Consulates. It allows five days in Constantinople. The excursionists, having visited Constantinople, may return vid Trieste by putting into Athens and Corfu, the additional price being 425 crowns. Constantinople is left on September 11th, and Trieste is reached on September 16th.

Excursion No. 6, Bosnia, Herzegovina, Dalmatia, and the Hungarian Littoral, leaving Budapest on September 4th, and returning on September 12th. First-class, 320 crowns: second-class, 270 crowns.

The latest date of entry for any of the excursions is

The latest date of entry for any of the excursions is August 1st, and in each case a booking fee has to be paid, varying from 25 to 50 crowns, which is not repayable under any circumstances. Some of the excursions are necessarily limited in number, so that early application is desirable. So far as can be told at present, the Congress appears to be viewed with favour by the medical men of the United Kingdom, for it has secured a larger number of adherents than any of the Congresses since the one held in Paris. Communications should be addressed to the Hon. Secretaries for Great Britain, Dr. Clive Riviere and D'Arcy Power, Esq., F.R.C.S., 10A Chandos Street, Cavendish Square, London.

#### HOTELS AND LODGINGS.

The arrangements made for lodging members who attend the forthcoming Congress at Budapest are given in a circular letter dated April 15th, 1909. The letter is sent by the Central Travelling Ticket Office, iv Vigadó-ter, I. Budapest, Hungary:—

"We have been entrusted to find accommodation for the partakers of the above-mentioned Congress, and this we perform in advance and for the whole duration of the Congress by issuing 'accommodation orders.' The period of validity for such accommodation orders is seven days with hotels and eight days with private dwelling-houses, and it is to be understood that the day of arrival with hotels is August 28th, but with private dwelling-houses August 27th. Should the arrival at Budapest take place after August 27th, or with hotels after August 28th, and the departure from Budapest before September 4th, no reimbursement will be made for the time the lodgings are unused. At the same time we are able to dispose of chambers at the following prices:—

"In Hotels—Arrival on August 28th and departure on September 4th.—Rent for a stay of seven days (prices in kronen): Series A.—Single-bedded, 70-140k.; double-bedded, 84-210k.; three-bedded, 105-245k. Series B.—Single-bedded, 48-69k.; double-bedded, 64-83k.; three-bedded, 80-104k. Series C.—Single-bedded, 21-47k.; double-bedded, 35-63k.; three-bedded, 42-70k.

"In private dwelling-houses—Arrival on August 27th, departure on September 4th.—Rent for a stay of eight days (prices in kronen): Series D.—Single-bedded, 51-70k.; double-bedded, 75-100k.; three-bedded, 91-115k. Series E.—Single-bedded, 31-50k.; double-bedded, 45-75k.; three-bedded, 61-90k. Series F.—Single-bedded, 45-60k. (For practical purposes kronen may be reckoned as the equivalent of shillings).

"Such chambers must be engaged in the following.

"Such chambers must be engaged in the following way:—The person who orders lodgings indicates in which series and at what price he desires a single-bedded room, or one with two or three beds, and whether in an hotel or in a private house. It is left to the choice of him who engages the room to fix the price between the maximum and the minimum rent, and the amount corresponding with the price chosen must be sent to us in advance. In return for it, and in conformity with the order received, we remit the sender an accommodation order for an appropriate lodging.

lodging.

"To recompense our trouble and expenses in securing accommodation, the Presidency of the Congress has stipulated a commission of 8.50k. per person. This commission is to be sent at the same time as the rent, and the receipt of it will be acknowledged separately, because the accommodation order only acknowledges the receipt of the rent which we have to pay for the respective lodgings without any deduction.

"In case the renter should be prevented from coming and taking possession of the lodgings—notice of which, however, must reach us before August 20th—the rent paid in advance will be refunded upon production of the accommodation order, with a deduction of 10k. a head; should such notice reach us after August 20th 20k. will be deducted per person.

a head; should such holice reach as after regard 2 20k. will be deducted per person.

"You will oblige us very much by taking into-account the tables above mentioned, fixing upon a room suitable to your purpose, and by kindly remitting to us the corresponding rent, in addition to the commission, whereupon we shall immediately deliver you the necessary 'accommodation order.'"

The text of this communication is given without comment, though members who propose to avail themselves of the proposals contained in it are requested to consider it carefully, and to keep every document in connection with their bargain, as failure to produce written evidence of the contract proved a fruitful source of trouble at the Madrid meeting of the International Medical Congress.

#### OBITUARY.

THE LATE SIMEON SNELL, D.Sc., F.R.C.S.ED.
THE following appreciatory notice has been sent by a personal friend:—

a personal friend:—
Simeon Snell, that bluff and hearty West-Countryman, died at his residence, Moor Lodge, Rutland Park, Sheffield, on April 17th last, after an illness that had lasted for several months. He possessed a most attractive personality, together with a potentiality for work that was simply amazing. He was never idle, and, indeed, did not seem to know the meaning of the word. As he once remarked to the present writer, he wished "the day contained not twenty-four, but forty-eight

hours." His large private practice, his duties in connection with the University of Sheffield, and his immense clinic at the Sheffield Royal Infirmary would have given ample occupation to most men. Not so Snell. He made time during his busy life to act as sophical Society, of which he afterwards occupied the Presidential Chair. His was the hand that guided the amalgamation between that Society and the old Sheffield Book Club. In conjunction with the late Mr. J. D. Leader, Snell wrote the "History of Sheffield Royal Infirmary," an institution to which he was attached in the capacity of Ophthalmic Surgeon for many years. He founded and edited the Quarterly Medical Review. Snell filled a large and honourable part in the public life of his adopted town, Sheffield. For many years he had been a Justice of the Peace, and a touching tribute was paid to his memory only the other day by the solicitors practising in the local police court. Nobody did better work than Snell in the movement that led to the foundation of Sheffield University. He addressed many meetings in Sheffield University. He addressed many meetings in Sheffield and district, and in that way rendered yeoman service to the scheme. Snell filled many posts with much acceptation. He was, as already said, Ophthalmic Surgeon to the Sheffield Royal Infirmary, and was besides Professor of Ophthalmology at the University, Ophthalmic Surgeon to the Blind School, and, most important of all, filled at the time of his death the distributed of the Sheffield of the Sheffield at the said t Important of an inheat the thine of the British Medical Association. He had been Vice-President of the Ophthalmological Society of the United Kingdom. As a practical surgeon, Snell took front rank. He was an accomplished operator, and at the Royal Infirmary (where there is a special eye block) he used to exhibit with some pride a large wide-mouthed bottle filled to repletion with cataractous lenses that he had removed from Infirmary patients. On a rough estimate, the receptacle must have contained several hundred lenses. Snell's was essentially a practical mind. This was shown by the nature of his work, which, in the main, may be said to have dealt with the diseases and accidents of industrial life. He was the greatest authority living on that curious affection, miners' nystagmus, and his work on the extraction of foreign bodies from the eyeball by the electro-magnet is known the world over.

APRIL 28, 1909.

It was evident to his friends that he was far from well when the British Medical Associatian met last summer in Sheffield. Still, he managed to compass the more important work. He seldom appeared in the Section of Ophthalmology, although at the end of the session he gave a most interesting luncheon at the Infirmary to many of its members. Snell's old teacher, Mr. Pridgin Teale, F.R.S., had come from retirement to make one of the party, and so had Dr. Argyll Robertson, who now, alas! has joined the majority. Professor Fuchs, of Vienna, and Professor Axenfeld, and Freiburg were also present. Not the least touching of Freiburg, were also present. Not the least touching feature was the presence of Mr. Michael A. Teale, son of the veteran Teale, and of Mr. Snell, son of the host. A good man has gone. May his soul rest in peace! SYDNEY STEPHENSON.

#### SEPTIMUS GIBBON, M.D.CANTAB., F.R.C.P.

WE regret to announce the death of Dr. Septimus Gibbon, at his London residence, at the age of 84 years. Deceased was the son of Mr. William Gibbon, surgeon, of Kettering, Northamptonshire. His grandfather, whose name was MacGibbon, came from Edinburgh

Dr. Gibbon won an exhibition to Clare College, Cambridge. He was resident House Physician at Addenbrooke's Hospital, and took his degree of M.B. in 1851, and the M.R.C.P. of London in 1852. He afterwards proceeded to St. Bartholomew's, where he was a pupil of Sir James Paget. During the war in the Crimea he went out with Miss Florence Nightingale to the British Civil Hospital at Smyrna, of which he

After a year's service he returned home and set up in practice in London, being an Assistant Physician at the London Hospital. He was Sanitary Officer of the

National Hospital for Paralysis and Epilepsy, and Medical Officer of Health for Holborn for nearly 40 years, and was one of the oldest managers of the Natural Philosophy at St. Bartholomew's Hospital, and was well-known in the City. He was editor and proprietor of the Pulpit and Ecclesiastical Review till within a few months of his death. Dr. Gibbon married, in 1858. Janet, eldest daughter of Thomas Jacomb, and leaves two sons and three daughters.

#### ROBERT HARRISON WILSON, M.D.DURH.,

M.R.C.S.
WE regret to announce that Dr. Robert Harrison Wilson, one of the oldest medical practitioners in the North, died suddenly last week at Tynemouth. He had not been well of late, but was out for his customary walk in the morning at Tynemouth, where he has resided for two years. He was taken ill, and died in the afternoon. Born at Howdon ill, and died in the afternoon. Born at Howdon eighty-two years ago, Dr. Wilson commenced practice in Gateshead early in the 'fifties, and came into great prominence for his efforts during the cholera epidemic which raged in 1854. Previous to taking up his residence in Gateshead, Dr. Wilson held an appointment at Newcastle Infirmary. For some years he was Poorlaw medical officer in Gateshead, and up to his death was an hon. physician of the Dispensary. Six years ago he retired into private life his practice being conago he retired into private life, his practice being continued by Dr. Norris and Dr. Moore Ede, and two years ago he removed to Tynemouth. Dr. Wilson was a magistrate.

#### REVIEWS OF BOOKS.

#### INFANT FEEDING. (a)

THERE is, perhaps, no subject on which medical students, and practitioners for that matter, are so badly informed as infant feeding. It is one which is usually utterly neglected in the medical curriculum, and yet in actual practice it is of first importance. In fact, infant feeding is a national question, and demands the immediate attention of every medical man. As a rule, books on the subject are too theoretical to be of any help to the seeker after knowledge. He has to grope about amidst a labyrinth of theory. Facts are what he wants, but they are hard to find. This cannot be said of the book under review. The first impression one gets after reading its pages carefully and critically is that it is pre-eminently practical. Dr. Fowler, on the very first page, refers to gain in weight as a valuable sign of successful artificial feeding, but he is careful to point out at the same time that some infants, even though putting on weight, may be developing rickets. In such cases the feeding cannot be looked upon as a success. Too often reliance is placed on this gain in weight as an absolute sign that the child is doing well. This to our mind, and evidently to the author's, is one of the commonest of fallacies.

Dr. Fowler insists on the impossibility of finding a food identical with woman's milk. Human milk, as he points out, possesses specific natural properties which cannot be imitated artificially. Regarding the digestion of milk proteids, the author evidently favours the views recently put forward by Van Slyke and Hart. A somewhat original scheme of casein digestion is given by way of illustration which puts the matter in a light which will prove new to many. Dr. Fowler rightly condemns the use of preservatives as a means of sterilising milk. Boron preservatives are bad enough, but hydrogen peroxide is, in our opinion, much more likely to do harm. Buddised milk has, author's experience, frequently caused scorbutus in infants fed exclusively on it. He maintains, however, that the use of sterilised milk is probably not a cause of scorbutus. Among the poor he advocates boiling the milk for 5 to 10 minutes as being safe and satisfactory. Buttermilk has, in the author's hands, proved very

(a) "Infant Feeding. A Practical Guide to the Artificial Feeding of Infants." By J. S. Fowler, M.D., F.R.C.P.Ed., Physician to the Royal Hospital for Sick Children, Edinburgh. London: Henry Frowde. 1909.

successful in certain selected cases of chronic gastrointestinal disorder. His experience, however, in producing Luttermilk artificially by means of cultures of lactic acid bacteria has not been encouraged. Regarding proprietary infant foods, Dr. Fowler writes:-"Most proprietary foods are inadequate, usually in fat; all are liable to produce scurvy. Claims that they are identical with human milk are wholly illusory." This sentence is but one of many truths contained in this admirable volume. The medical man who follows the teaching contained within its pages will not go very far astray. Although the subject has been treated from a scientific standpoint, the book is essentially practical in its style. It is written by one who knows the many pitfalls that beset the uninitiated when dealing with the difficulties of infant feeding.

THE URIC ACID FACTOR IN DISEASE. (a) DR. HAIG'S opinions are now so well known to the profession that any detailed criticism of the seventh edition of his work is unnecessary. Originally published in 1892, the book has grown considerably, and the present edition contains nearly a thousand pages. The course of his investigations has not led Dr. Haig to modify in any material point the views that he put forward sixteen years ago, but has rather tended to strengthen his belief in the truth of those views. Stated shortly, these views are that many functional and organic diseases are the result of the accumulation of uric acid in the blood and tissues, and that this uric acid is mainly derived from animal food. The treatment is obvious: avoid taking uric acid in food, and the cause being thus removed, the effect will disappear. One must not, however, be disappointed if the result does not completely come up to one's expectations, for our bodies, like those of our forefathers, have been damaged to a serious degree by prolonged poisoning. One has the comfort, however, of knowing that those who follow us some three or four generations hence will reap the benefit of our abstinence. Like other special pleaders, our author is so taken up with the demonstration of his own special views that he has no time for the consideration of other matters. If we take, for example, the chapter which deals with headache, we find that the "uric acid headache" is, in Dr. Haig's opinion, the same as migraine, but in the causation and treatment of this condition we do not find anything said about eyestrain as a cause, or its removal as a form of treat-ment. Surely, in the treatment of this disease, the neglect to investigate the condition of the eyes would the be a grave omission on the part of any physician. The book reminds us not a little of a play that had some vogue a few years ago, and which, though it contained much truth, could hardly be looked on as a complete exposition of pathology and therapeutics.

OUR TEETH. (b) THE importance of sound teeth to the well-being of the race is gradually coming to be recognised by the medical profession, not only as an asset in itself, but also as a means of preventing many diseases the result of bacterial infection. The public have not yet got satisfactory ideas on the subject, but signs are not wanting that such ideas are beginning to be recognised. Perhaps the most striking evidence of the nised. Perhaps the most striking evidence of the wrong ideas which too many people hold about teeth is to be found in the view so commonly expressed about the temporary teeth of children. If the attention of parents is directed to decayed teeth in the mouths of their children, how often do we hear the answer, "It is only their first teeth, and so does not matter." The result of this is too often seen in our dental hospitals in the numbers of young men and women who apply to have extensive extraction operations performed in order to get fitted with artificial dentures. If the teeth of the adult are to be good, too much attention can hardly be paid to the temporary teeth of the child.

A remedy can only be found for this by the education of those in charge of children in the necessity of attention to the child's teeth. The book before us is an endeavour to help on this education, and as such we extend it a hearty welcome. We think it a pity, however, that our authors have devoted so little space to what we look on as the most important part of the book-how to preserve the teeth. Instruction for the public in such matters must be dogmatic, and we fear that the admirable chapters dealing with the growth and formation of the teeth will tend to limit rather than to increase the utility of the book where it is most needed. We trust, however, that it will find many readers not only among the public, but in the profession, for, if it does, good can hardly fail to result to succeeding generations.

#### LITERARY NOTES.

THE present volume of the great American work, "Index-Catalogue of the Library of the Surgeon-General's Office," includes references under the words, periodicity and others up to "Prussia," and includes 5,966 author titles, representing 3,250 volumes and 4,851 pamphlets. It also contains 7,678 subject-titles of separate books and pamphlets, and 40,221 titles of articles in periodicals. The list takes in such important subjects as peritonitis, perityphlitis, phagocytosis, plague, pleurisy, pneumonia, and pregnancy. It would be almost impossible to exaggerate the importance and value of this Index-Catalogue to the THE present volume of the great American work, portance and value of this Index-Catalogue to the student of medicine, and medical men throughout the world are under a deep debt of gratitude to the U.S. Government for their liberality in providing such a work.

MR. RUDVARD KIPLING'S many admirers will be glad to have in permanent form the address on "Doctors," delivered to the students of the Middlesex Hospital last October. (a) The address loses none of its eloquence or freshness in re-reading. It is here accompanied by a Preface from the hand of Mr. Reginald Lucas, which deals with the history of the Middlesex Hospital. The Preface is interesting, but eleven pages of Mr. Lucas to introduce eight pages of Mr. Kipling seems to show a lack of sense of proportion. Less necessary still is the reprinting of Oliver Wendell Holmes' mediocre verses on "The Two Armies." The booklet is sold for the benefit of the Middlesex Hospital.

H. K. Lewis has in preparation a new book on "Immunity and its Applications in the Diagnosis and Treatment of Infectious Diseases," by Dr. D'Este Emery, the author of "Clinical Bacteriology and Hæmatology," which has reached its third edition. The book aims at giving a clear outline of the main facts and theories in regard to immunity, and is not written in support of the view of any particular school. It is intended in the main for students commencing the study of the subject or for practitioners wishing to learn the scientific basis and exact mode wishing to learn the scientific basis and exact mode of application of the modern methods of diagnosis and treatment of the infectious diseases. The book also contains a Glossary of Terms and an extensive Bibliography. The Lectures delivered at the University of London in February, 1909, by Dr. Louis C. Parkes, under the trust of the late Sir Edwin Chadwick, and also just ready for publication. The Parkes, under the trust of the late Sir Edwin Chauwick, are also just ready for publication. The official title of the course was "The Medical Aspects of Recent Advances in Hygiene as Connected with Sewering," but Dr. Parkes has called the book, "House-Drainage, Sewerage, and Sewage Disposal in Relation to Health." The same firm has just issued a fourth edition of Binnie's "Operative Surgery." The service of the Extremities has been omitted but in section on the Extremities has been omitted, but in spite of this the revisions and extensions increase the number of pages and illustrations, over the third edition.

#### THE MEDICAL PRESS. 435

#### MEDICAL LITERATURE, RECENT SUMMARY OF ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

Werthelm's Pan-hysterectomy for Carcinoma of the Werthelm's Pan-hysterectomy for Carcinoma of the Cervix.—Berkeley (Journ. Obst. and Gyn. of the British Empire, XV., 3).—For the purposes of this paper the author sent a private circular to every recognised gynæcologist in the United Kingdom. The number of cases thus collected of radical abdominal operations for cancer was 313, of which 243 were Wertheim's. The fact that if a Wertheim's operation is to be performed, whatever else is done, the varing must be formed, whatever else is done, the vagina must be clamped across below the growth before it is divided, seemed to the author not to be generally recognised. The author discusses the following points: What advantage has Wertheim's operation over simple advantage has wertherm's operation over simple vaginal hysterectomy, and what over para-vaginal section. With regard to simple vaginal hysterectomy, he considers: (1) Primary mortality. This is undoubtedly high, but, with increased experience, can be lowered. This is shown by Wertheim's results. Of the 243 cases collected by the author the mortality was 18.1 per cent.; that of all the radical operations (313) is 18.5 per cent. This compares badly with vaginal hysterectomy, in which the mortality with different operators varies from 14 to 4 per cent.; but this fact should not deprive patients of the chance of cure, as, after all, this increased mortality is mostly because cases of a much more advanced and serious nature can be and are treated. If the percentage mortality is reckoned according to whether the case is one of early, moderate, or advanced type, the author finds in 238 cases collected the following results:—In 33 early cases, 6.3 per cent.; in 19 moderate cases, 5.2 per cent.; in 186 advanced cases, 23.1 per cent. (2) Percentage operability is greatly increased by the radical abdominal operation, because one is able to separate the bladder, rectum, and ureter from the growth without much risk of injury, whereas by the vaginal route out much risk of injury, whereas by the vaginal route this is impossible in a large number of cases. It was not possible to estimate the percentage operability from the reports collected, but on the Continent this varies from 46 to 90, and probably about 60 per cent. represents the true figure. This is greatly in advance of vaginal hysterectomy, the highest return of which is 31, and in the experience of English operators is nearer 12. (3) Percentage of cures. If the uterus is removed by vaginal hysterectomy, practically all the parametrium is left behind. By Wertheim's method all the parametrium is removed, and also a large portion of the cellular tissue. The results of the pathological investigation of the parametrium of a large number of cases has convinced the author that this should always be removed. The parametrium is infected in 60 per cent. of the cases, and therefore half the vaginal operations are useless. The pathological findings have proved that it is impossible to The pathodiagnose clinically the real condition of the parametrium. since a hard one may contain no cancer and a soft one be full of cancer. Five years appears to be the period chosen by most authorities, after which a patient may be said to be cured. tics collected by the author are useless for the purpose under discussion, as nearly all the operations have been done within the last two years. On the Con-tinent the standard is fulfilled. Wertheim has 62 per cent., and others vary down to Bumm, with 30 per cent.; but, in comparing these, it must be taken into account the varying percentage operability of the different operators. Wertheim has 49; Bumm, 90. In looking up the statistics of vaginal hysterectomy, the author found percentages of cures after five years to author round percentages of cures after five years to vary from 12 to 1.2. In comparison with this, Wertheim's operation shows a vast improvement, and this the author considers is due to two facts—one, the removal of the parametrium, the other the prevention of infection by clamping the vagina below the growth. In the past recurrence of cancer after removal of the

diseased cervix has nearly always been local from cell implantation, while after Wertheim's operation local recurrence is a rarity. Even if the percentage of cures with Wertheim's operation was no better than by vaginal hysterectomy, still the actual number of cases would be greater owing to the increase in operability. The author also points out that even when recurrence does take place, the patients do not suffer the same wertheim's operation with Schauta's para-vaginal section, the chief point for discussion seems to be whether there is any benefit to be derived from the removal of the regional glands. Theoretically there is any benefit to be derived from the removal of the regional glands. much in favour of the removal of the glands, and, if this were possible, it would be a strong point in favour of the abdominal route; but, in fact, it is impossible, and statistics seem to show that nearly always when glands have been removed and found to be infected there has been a recurrence. Besides this, the removal of glands prolongs the operation, and so increases the primary mortality. Viet, Pankow, and Wertheim hold that the routine extirpation of glands does not help the case, and the latter remarks that since in only one-third of the cases are the glands involved, the routine removal is detrimental to two-thirds of the cases, and increases the primary mortality in them. The occasional cure of a case in which the glands are infected does not counterbalance the extra mortality due to routine extirpation. If it is considered that the removal of the glands is not beneficial, the question of Wertheim's or Schauta's operation is a matter for personal choice by the operator, as the statistics of the two operations are almost similar as regards operability and permanent cure, while Wertheim's operation shows a higher primary mortality, probably owing to the removal of glands. The author deals with the complications which may arise during Wertheim's operation. On the question of drainage there seems to be some divergence of opinion. Many surgeons have given up draining the peritoneal cavity, while, on the other hand, Bumm claims to have reduced his mortality from 47 to 15 per cent. by stitching the peritoneum to the edges of the vagina and so leaving free drainage of the peritoneal cavity. The author also illustrates a single clamp, to take the place of the two clamps used by Wertheim for closing the vagina below the growth.

Primary Carcinoma of the Fallopian Tube, and the Report of a Case.—Norris (Surg., Gyn., and Obst., VIII., 3).—The author reviews the previous literature on this subject, and has collected 23 reported cases since 1904, which, together with those collected by Doran, and reported in 1905, brings the total number to about 86. He concludes that the condition is about 100 times as rare as uterine cancer. The growths can probably be all classified under the two heads papillary and alveolar, the former being by far the more Inflammation usually precedes the cancer. The condition may occur as a degeneration of a benign papilloma, but is usually primarily malignant, of rapid growth, and gives early metastasis. The symptoms are watery, blood-stained leucorrhea and atypical hæmorrhage, usually occurring between 40 and 50 years of age. The symptoms are often masked by those of pre-existing pelvic inflammatory disease, and the condition found on pelvic examination usually simulates this. A tube the seat of a cancer usually resembles a hydrosalpinx until the contents are examined. author's case was æt. 27, and had a history of pelvic inflammation four years previously. There was induration at both sides of the uterus, which was somewhat fixed by inflammatory masses at the sides and posterior, and the diagnosis made was bilateral pelvic inflammatory disease. The uterus and appendages

were removed owing to the advanced stage of the inflammation. The pathological examination of the specimens showed inflammatory disease of both appenspecimens showed inflammatory disease of both appendages, but the lumen of the right tube was occupied by a papillomatous growth of definitely malignant type, and at no part suggesting a benign tumour. The other organs were quite free from any suggestion of malignant growth. This seemed to be confined to the inner portion of the right tube. The age of the patient was considerably under the average was considerably under the average.

Persistent Bacteriuria.—Geraghty (Johns Hopkins Hospital Bulletin, January, 1909) discusses this subject, giving notes of cases under his own observation. He finds that the organisms most commonly present are the staphylococcus albus and the bacillus coli communis. The condition he believes to differ only in degree from ordinary cystitis. In one the infection is present without any inflammatory reaction on the part of the bladder wall; in the other the infective agent is in the urine, and there is also involvement of the vesical mucosa. He has never heard of a case in which the bacteriuria was due to any of the more strongly pathogenic organisms, such as the staphylococcus aureus. He therefore concludes that only slightly pathogenic organisms can produce bacteriuria, the more strongly pathogenic producing an inflam-matory reaction. It is found that the bacillus coli does not alter the reaction of the urine, whereas the staphylococcus albus turns it alkaline, and a troublesome phosphaturia may arise. The author in all his own cases attempted vaccine treatment with vaccines made from the patient's own organism, but the results were entirely negative.

#### MEDICAL NEWS IN BRIEF.

#### Royal College of Physicians of Ireland—Presidential Dinner.

THE President of the Royal College of Physicians of Ireland entertained his Excellency the Lord Lieutenant, the Fellows of the College, and a number of his other friends at dinner in the College Hall on Saturday last. After dinner, which was most admirably served, the toasts of the King, the Lord Lieutenant, and the President were duly proposed. His Excellency, in the course of his speech, referred at length to past medical history, and particularly to old Irish medical worthies. After the toasts the guests adjourned to the Statue Hall of the College, where a very pleasant musical programme was gone through. His Excellency gave particular pleasure to the company by singing

#### Medical Sickness and Accident Society.

At the usual monthly meeting of the Executive Committee of this Society, held on the 16th inst., it was reported that as usual at this time of the year the number of sickness claims are large; but for the most part they have been of short duration, and the total amount disbursed in respect of them is less than in the corresponding period of last year. mittee examined the drafts of the quinquennial valuation and annual report. The business of last year was exceptionally good, and the twelve months working has for its result a substantial increase, both in the number of members and in the financial reserves of the Society. The quinquennial valuation report will also be found to be good and the Committee will be enabled to recommend to the members a continuance of the payment of the liberal scale of bonus arranged for in 1904.

#### Incorporated Institute of Hygiene.

A MEETING of the members and associates of the Northern Counties Branch of the Incorporated Insti-tute of Hygiene was held at Rutherford College, New-

castle, on April 22nd, Mr. J. R. Hedley in the chair.
The Chairman, in addressing the members, said
whilst it was well known, and he might say an acknowledged fact, that England was equal to, or even in advance of many countries in what might be called

municipal hygiene, he was afraid they could not regard themselves as equally advanced in the knowledge of hygiene of domestic life. In this science he had every reason to believe both France and Germany excelled, but they excelled only because they had been less apathetic, because they had not been content, generation after generation, to take things as they were. It was to such bodies as the Institute of Hygiene that they must look for advancement in these

Dr. Appleby, the hon. secretary, referred to the work of the past year and remarked upon the success in the number of members. At the beginning of the winter session a class was formed at Rutherford College for the special training of those who wished to take up a course of study in school hygiene. As would naturally be expected those engaged in the teaching profession formed the greater part of that class, and he had no doubt the numbers who had attended were indications both of the importance school teachers attached to that particular branch of their work and the need there was for that knowledge.

Councillor Dr. Stewart drew attention to the necessity

there was for the spread of knowledge in the ordinary

details of nursing of everyday life.

Dr. T. M. Clayton, Medical Officer of Health, Gateshead, said he agreed with the remarks of Dr. Stewart. Not until the women of this country recognised their home responsibilities and equipped themselves to meet those requirements, would any improvement take place in their homes.

## Society for the Relief of Widows and Orphans of Medical Men.

A QUARTERLY Court of the Directors of the above Society was held on Wednesday, April 14th, Dr. Blandford, President, in the chair. Eleven directors were present. Since the last court, three members of the Court had died—Mr. T. Laurence Read, Vice-President, and Dr. Eastes and Dr. Chas. Baker, directors. A vote of condolence was passed to the directors. A vote of condolence was passed to the families of these gentlemen. Application for membership had been received from two medical men, and they were duly elected members of the Society. One of the annuitants, an orphan, had died. Her mother, up to the time of her death, had also been in receipt of grants. The father had paid in subscriptions £14 14s., and his widow and orphans had received from the funds of the Society £960. Five letters asking for relief had been received from widows of medical men, but this had to be refused, as their husbands were not members of the Society. Membership is open to any registered medical practitioner who at the time of his election is resident within a twenty-mile radius of The subscription is two guineas per Charing Cross. annum, and relief is only granted to the widows and orphans of deceased members. Full particulars may be obtained from the Secretary, at the offices of the Society, II Chandos Street, Cavendish Square, W. The invested funds of the Society now amount to over (100,000. Thursday, May 20th, was fixed for the annual general meeting, due notice of which will be posted to the members on May 1st.

#### PASS LISTS.

#### University of Aberdeen.

At the Spring Graduation at this University on April 6th, the following Degrees were conferred:—
Degree of Doctor of Medicine (M.D.).—William Angus, M.B., Ch.B.; Robert Chalmers, M.B., Ch.B.; Horatio W. A. Cowan, M.B., C.M.; James A. Davidson, M.B., Ch.B.; James Raffan, M.B., Ch.B.; Alexander H. Skinner, M.A., M.B., Ch.B.

The Degree of Master of Surgery (Ch.M.). was granted to James Robertson, M.D., Ch.B., with Honours, for his Thesis on "The Newer Methods in the Diagnosis of Urinary Disease."

Degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.).—\*Alexander Greig Anderson, M.A. (with Second Class Honours), \*William Anderson, David M. Baillie, John A. Beattie, James C. Bell, Douglas W. Bruce, Alexander At the Spring Graduation at this University on

J. D. Cameron, Arthur H. Duckett, William M. Duguid, Naughton Dunn, M.A., James Elder, John D. Fiddes, M.A., B.Sc., George C. Grant, Adam Gray, Herbert Hargreaves, John Inkster, \*William W. Jameson, M.A., Harold G. R. Jamieson, John Johnston, Clement R. Macleod, John McPherson, Angus Macros \*Charles A Macson M.A. John J. Mannier Johnston, Clement R. Macleod, John McPherson, Angus Macrae, \*Charles A. Masson, M.A., John L. Menzies, Robert J. Merson, Herbert S. Milne, John Mitchell, Dawson C. Robertson, Finlay G. M. Ross, Herbert A. Smith, George C. Soutter, Douglas M. Spring, Augustus G. Stewart, M.A., Robert Sturrock, Charles C. Twort, Alfred J. Williamson, M.A., Alexander Wilson. (\* Passed Final Professional Examination with this literature 2009) with "Distinction.")

Diploma in Public Health.—George Davidson, M.B., Ch.B.Aberd.; John Ferries, M.B., Ch.B.Aberd.; Alexander F. MacBean, M.A., M.B., Ch.B.Aberd.; Rae McRae, M.B., Ch.B.Aberd.; Arthur J. Milne, M.B., Ch.B.Aberd.; William G. Watt, M.B., Ch.B. Aberd.; Thomas C. M. Young, M.B., Ch.B.Aberd.

## Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, and Faculty of Physicians and Surgeons of Glasgow.

THE quarterly Examinations of the above Board, held in Edinburgh, were concluded on 19th inst., with

the following results:-

the following results:—

The following candidates passed the First Examination:—Samuel Wright, Claud Aldeus Slaughter, Jamshed H. Apoo, Hormazd A. Topalia, Joseph Muller, Walter Lessey, Bhajiwalla F. Limji, James G. Lessey, Hugh G. Anderson, Vasudeo D. Nimbkar, Sara A. Anthoni, Robert B. Galt, Evan Ithel Parry, and 6 passed in Physics: 3 in

Sara A. Anthoni, Kopert B. Cart, Evan Time, Larry, and William Bird; and 6 passed in Physics; 3 in Biology, and 10 in Chemistry.

The following candidates passed the Second Examination:—Robert H. Thomson, Stanley D. Large, Alexander E. MacKenzie, Frederick R. Lucas, John R. Smith, Arthur Butterfield, Octavus W. Bateman, William F. Gibb, Thomas R. G. Melrose, Frank D. Johnson, Kedar Nath, Victor T. W. Eagles, James A. Frost, John Ross, Emmanuel P. Ghose, Husain Buksh, Prabooth C. Banerjee, and William W. W. Watt; and 2 passed in Anatomy and 9 in Physiology.

The following candidates passed the Third Examination:—Joseph Muller, Charles G. Timms, Robert M. M. Wilson, Baboorao G. Shiroadkar, Charles L. Ievers, Richard Parry, Jugal K. Sharma; and 5 passed in Pathology and 6 in Materia Medica.

The following candidates having passed the Final Examination were admitted L.R.C.P.E., L.R.C.S.E., and L.F.P. and S.G.:—James Robert Le Touzel, Canada; Charles Liston Stewart, India; Hargobind Lal Batra, India; Bhola Nath, India; Charles William Gee, Wigan; Thomas Mohan, Ireland; Harold Webb Gee, Wigan; Inomas Monan, Ireland; Harold Webb Garcelon, America; William Rutherford Waddell, Belfast; Claude Ernest Watts, Dewsbury; Frederick Robert Watson, New South Wales; Stanley Welton Hogg, New South Wales; John McKelvey, Belfast; Henry Hollister Jackson, Victoria; Alexander McMurray, Belfast; Albert Edward Herat, Ceylon; William William Control of the Cont Whitfield, Ireland; Robert George Sherlock, Jamaica; Whitfield, Ireland; Robert George Sherlock, Jamaica; James McTurk, Wales; Andrew Johnstone Brown, Edinburgh; Jehangir Munchershaw Mehta, Bombay; Jal Maneckji Mody, Bombay; Thomas Graham Shand, Greenock; Ralph Holwell Gray, Hants; Kharshed Nowroji Khory, India; Martin Luther Burke, Jamaica; Thomas James George, England; Jehangir Edulji Spencer, Hydrabad, Deccan; and 8 passed in Medicine and Therapeutics, 12 in Surgery and Surgical Anatomy, 22 in Midwifery, and 25 in Medical Jurisprudence. Medical Jurisprudence.

#### The Royal University of Ireland.

THE following candidates have passed the under-

mentioned examinations :-

The M.D. Degree Examination.—Daniel Gillespie, M.B., B.Ch., B.A.O.; William R. Hayden, M.B., B.Ch., B.A.O.; Robert Johnston, M.B., B.Ch., B.A.O.; William I. Leighton, M.B., B.Ch., B.A.O.; Andrew Leitch, M.B., B.Ch., B.A.O.; Robert McCarrison, M.B., B.Ch., B.A.O.; James H. Stewart, M.B., B.Ch., B.A.O.

The M.B., B.Ch., B.A.O. Degrees Examination.—

Upper Pass.—Edward Forbes, Patrick Keelan, Alan Kidd, James M. O'Connor, B.A., Thomas Taylor, Verner Wiley, John M. Williams.
Pass.—Thomas P. Carroll, John A. Clarke, B.A., Edgar M. Condy, William T. Henderson, William F. Hooper, Caroline V. Lowe, Samuel W. McComb, John P. Moore, Harris Newman, Peter H. O'Connell, James I. O'Kelly, B.A., Edward O'Reilly, Robert H. Robinson, William H. Sheffield, Michael Shipsey, William S. R. Steven, Standish I. Watson, Bruce A. West.

West.

The following candidates may present themselves for the further examination for Honours in the subjects mentioned after their names:—Thomas P. Carroll, Midwifery; Edward Forbes, Midwifery; Patrick Keelan, Midwifery; Alan Kidd, Medicine; Peter H. O'Connell, Surgery; James M. O'Connor, B.A., Medicine, Surgery, Midwifery; James I. O'Kelly, B.A., Medicine; Verner Wiley, Medicine, Surgery, Midwifery; John M. Williams, Medicine.

The following candidates have passed the Second Examination in Medicine:—

Udden Pass.—Samuel R. Armstrong, Thomas P.

Upper Pass.—Samuel R. Armstrong, Thomas P. avv. Norman B. Graham, B.A., Thomas Hill, Davy, Norman B. Graham, B.A., Thomas Hill, James J. Keirans, John J. H. Mitchell, Henry F. Moore, Michael D. Staunton. All the above candidates may present themselves for the further Examination for Honours.

Pass.—William F. Alges, Christopher Barragry, Daniel J. Barrett, Maurice J. Cogan, Samuel H. Davison, Rernard Doyle, B.A., Edmund C. Fawcett, Cecil L. Gaussen, John M. Gibson, Norman C. Graham, Gerald S. Harvey, George H. Hayes, Edward L. Garage Leckson, Lorges Lyong Loby, Lyong Lorges Lyong Loby, Lyong Graham, Gerald S. Harvey, George H. Hayes, Edward Heffernan, George Jackson, James Lyons, John Lyons, Samuel McComb, Richard McCulloch, Michael McTing, Robert C. McMillan, Ivan W. Magill, Edward W. Mann, Robert Marshall, William Megaw, Alexander G. Mitchell, Harry H. Mulholland, James O'Connor, Philip Purcell, John M. Rowe, Hugh A. Skillen, Martin Sweeney, William M. Walker, James R. White

Exempt from further Examination in Anatomy and Physiology.—Walter N. Rishworth, Thomas Smyth,

Exempt from further Examination in Practical Chemistry.—James N. Ferguson, Herbert V. O'Shea, Joseph Porter.

Joseph Porter.

The following candidates have passed the Third Examination in Medicine:—Upper Pass.—\*Henry L. Barniville, B.A., \*Richard H. Batter, Norman L. Joynt, \*Stephen A. McSwiney, B.A., Laurence P. Mulligan, Peter I. Ryan, B.A. (Those marked with an asterisk may present themselves for the further examination for Honours.)

examination for Honours.)

Pass.—James S. Bellas, William K. Calwell,

6d. per line beyond.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

Ms. W. WILLIAMS.—The population of London and Greater London are treated separately in official statistics. The former is returned as having 4,833,938 inhabitants; the latter, which includes its suburbs, has 7,429,740 inhabitants. Even this latter figure does not include "The Outer Ring," for which no fewer than 2,595,802 additional must be taken into account.

than 2,595,802 additional must be taken into account.

FATAL ACCIDENTS.

Some interesting statistics will be found in the recently issued official returns of deaths during last year in England and Wales. The number of fatal accidents reported was 658. These do not, of course, include deaths of miners, which alone ran to 1,343 in 1968, nor to deaths from shipwrecks and accidents on board, from these there were 625 deaths. The total number of deaths by accident from all causes was higher than any year since registration has taken place, being 124 above the mean of the last five years. 

FOURTH YEAR (Edinburgh).—We have not seen the announce-ment, and think you must be confounding it with a work having a similar title, but by a different author.

### Meetings of the Societies, Tectures, &c.

WEDNESDAY, APRIL 28TH.

MEDICAL GRADUATES' COLLEGE AND POLICLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. A. Edmunds: Clinique (Surgical).

TRUERDAY, APRIL 29TH.

MEDICAL GRADUATES' COLLEGE AND POLICLINIC (22 Chenies Street, W.C.).—4 p.m.: Sir Jonathan Hutchinson: Clinique (Surgical).

Street, W.C.).—4 p.m.: Sir Jonathan Hutchinson: Clinique (Surgical).

Fridat, April 30th.

Rotal Society of Medicine (Clinical Section) (20 Hanover Square, W.).—8 p.m.: Cases: Mongols and Conditions that have been Confused with Mongolism: Dr. L. G. Guthrie, Dr. Sutherland, Dr. Morley Fletcher, Dr. Poynton, Dr. Langmead, and Dr. Harry Campbell. Mr. J. Jackson Clarke: Cases of Congenital Hip Disease treated by the Manipulative Method of 1904. Mr. W. G. Spencer: Reduction of an Old Subcoracoid Dislocation of Shoulder, Complicated by Fracture of Humerus, by Excavating the Glenoid Cavity. Dr. H. G. Turney: Trophædema following Trauma. Dr. Savill and Dr. P. Green: Solerodermia of the Extremities in a Woman the subject of Angeioneurotic CEdema. Mr. C. Gordon Watson: Double Infantile Coxa Vara treated by Subtrochanteric Osteotomy. Mr. H. B. Robinson and Dr. W. H. Bowen: Hereditary Transmission of Claw Hand and Foot in Mother and Child; Mother shown at the Clinical Society in 1887. 3.40 p.m.: Paper: Mr. W. Fedde Fedden: Six Cases of Infective Gangrene of the Extremities.

Royal College of Surgeons of England (Lincoln's Inn Fields, W.C.).—5 p.m.: Prof. Keith: On Specimens of Cleft Palate and Malformations of the Tongue. (Museum Demonstration.)

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Dr. J. Horne: Clinique (Ear, Nose, and Throat).

Central London Throat and Ear Hospital (Gray's Inn Road, W.C.).—3.45 p.m.: Lecture. Mr.

CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn Road, W.C.).—3.45 p.m.: Lecture: Mr. Stuart Low: Accessory Sinuses.

#### Appointments.

Fells, Arthur, M.B., C.M.Edin., Clinical Assistant at the Bristol Eye Dispensary.
Flemino, James Finlatson, M.B., B.S.Glasg., one of the Medical Referees under the Workmen's Compensation Act, 1906, for the Sherifidom of Fife and Kinross, and to be attached more particularly to the Dunfermline and Kinross District.
FOWLER, TROMAS WERB, M.D.Birm., one of the Medical Referees under the Workmen's Compensation Act, 1905, for County

Court Circuit No. 20, and to be attached more particularly to Coventry County Court.

FRENCH, MARGARET DOUGLAS, M.B., B.S.Durh., Junior Assistant Medical Officer at the North Riding Asylum, Clifton, York.

GIMBELY, RICHARD HENRY, M.R.C.S., L.S.A., Medical Officer for the Ippelpen District, by the Newton Abbot (Devon) Board of Guardians, for three years.

HOWDEN, IAN DALRYMPLE CLARK, M.D. Edin., one of the Medical Referees under the Workmen's Compensation Act, 1906, for County Court Circuit No. 49, and to be attached more particularly to Dover, Folkestone, Hythe, Rommey, Deal and Sandwich County Courts.

ROBERTS, WAITER R. S., M.B., Ch.B.Birm., Medical Officer of Health for the Ongar Rural District Council.

SQUIRE, E. W., M.B., B.S.Lond., House Surgeon to the Dreadnought Hospital, Greenwich.

STEVENSON, T. H. C. M.D. State Med. Lond., M.B., B.S.Lond., D.P.H.Cantab., Superintendent of Statistics of the General Register Office, Somerset House.

THOMAS, FRANK LESLIE, M.B., B.S.Lond., L.R.C.P.Lond., M.B.C.S., Honorary Ophthalmic Surgeon to the North Devon Infirmary, Barnstaple.

Infirmary, Barnstaple.

#### Vacancies.

Middlesex County Asylum, Napsbury, near St. Albans.—Fourth Assistant Medical Officer. Salary, £160 per annum, with furnished apartments, board, washing, and attendance. Applications to the Medical Superintendent. Victoria Hospital, Folkestone.—House Surgeon. Salary, £100 per annum, with board, residence, and laundry. Applications to the Secretary. York Dispensary.—Resident Medical Officer.—Salary, £130 a year, with board, lodging, and attendance. Applications to Dr. Swanson, The Pleasaunce, Heworth, York.

Lincoln Mental Hospital, The Lawn, Lincoln.—Assistant Medical Officer. Salary, £150 per annum, with board, etc. Applications to the Medical Superintendent.

Royal South Hants and Southampton Hospital.—House Physician. Salary, £100 per annum with rooms, board, and washing. Applications to T. A. Fisher Hall, Secretary.

Down County Infirmary.—House Surgeon. Salary, £60 per annum, with board and residence. Immediate application to Dr. Tate, Infirmary House, Downpatrick. (See advt.)

The Farringdon General Dispensary and Lyingin Charity, 17 Bartlett's Buildings, Holborn Curous, E.C.—Resident Medical Officer. Salary, £100 per annum, with rooms, attendance, fire, and lighting. Applications to Thomas Darrington, Hom. Secretary.

Ingham Infirmary and South Shields and Westoe Dispensary.—

Secretary.

Ingham Infirmary and South Shields and Westoe Dispensary.—
Senior House Surgeon. Salary, £100 per annum with residence, board, and washing. Applications to James B. Wheldon, Secretary, 74 King Street, South Shields.

#### Births.

JOHNSON.—On April 20th, the wife of W. Crosby Johnson, M.B., Ch.B., Fairleigh, Pendleton, Manchester—a daughter.

#### Marriages.

FAIRBANK—OGILVIE.—On April 21st, at Christ Church, Lancaster Gate, Harold Fairbank, M.S., F.R.C.S., son of the late Thomas Fairbank, M.D., of Windsor, to Florence Kathleen, younger daughter of the late Arthur Graeme Ogivie, of Sizzwell.

GIDEON—PIZA.—On April 21st, at 118 Sutherland Avenue, Maida Vale, the residence of the bride's parents, Eugene D. Gideon, M.B., M.R.C.S., L.R.C.P., eldest son of Mr. and Mrs. D. S. Gideon, Port Antonio, Jamaica, to Ruth Jessel, younger daughter of Mr. and Mrs. Judah Pizs.

LYON-CLARK—HOLT.—On April 28th, at Rt. Mark's, North Audley Street, London, W. Lyon-Clark, of Fremington, N. Devon, eldest son of Professor William Clark, M.A., D.D., LL.D., F.R.S.C., to Neille, only daughter of W. J. Holt, Esq., of Beckwith Knowle, Harrogate.

MACKENZIE—SKEGG.—On March 12th, at the British Episcopal Church, Foo-Chow, South Chins, the Rev. Marcus Mackenzie, B.A., M.B., C.M., of the Dublin University Fuh-Kien Mission, to Ethel Florence, youngest daughter of John J. Skegg, of Sideup, Kent.

REID—CLAFPERTON.—On April 21st, at the Church of St. Marylebone, London, Archibald Douglas Reid, M.R.C.S., L.R.C.P., of 39 Weibeck Street, London, son of Dr. Douglas A. Reid, of Teaby, to Annie Alian, daughter of the late John Clapperton, of Greezock.

ROWLETTE—DAY.—On April 22nd, 1909, at Greystones Church, by the Rev. W. M. Weir, Rector of Delgany, assisted by the Rev. E. S. Daunt, Rector of the Parish, Robert James Rowlette, M.D., 42 Lower Baggot Street, Dublin, younger, son of the late Matthew Rowlette, Carn Cash, Sligo, to Gladys Muriel, eldest daughter of the late Bussel Camper Day, B.A. (Oxon.), and of Mrs. Camper Day, Liscelta, Greystones.

#### Beaths.

BEEVOR.—On April 17th, at Croxley-green, Dame Emily Georgins, wife of Sir Hugh Reeve Beevor, Bu., M.D., of 17 Wimpole Street, London, and Hargham, Norfolk, and eldest daughter of Sir William Foster, Bt., of Hardingbam, Norfolk.

CARTER.—On April 26th, suddenly, at Oskhurst, Anerley, George Roe Carter, L.R.C.S.I., aged 68.

RANDELL.—On April 22nd, at 22 Vanbrugh Park, Blackheath, Edward Benjamin Randell, M.R.C.S.Eng., L.D.S., in his 73rd year.

# Peptogenic Milk Powder

## FOR MODIFYING COWS' MILK FOR INFANTS.

## Peptogenic Milk Powder

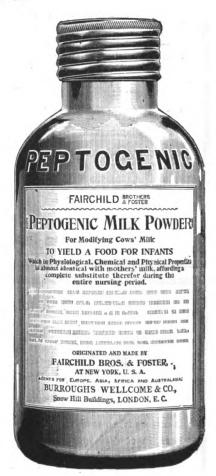

modifies and humanises cows' milk, by building it up to the standard of mother's milk.

## Peptogenic Milk Powder

by its action on the caseine, which becomes soft and flocculent, renders cows' milk as digestible and assimilable as human milk.

## Peptogenic Milk Powder

thus ensures that the infant's stomach shall have just the amount of work nature intends it to do.

## Milk thus prepared is Palatable

and suitable during the Whole Nursing Period.

Supplied to the Medical Profession in two sizes, at 1/10 and 3/8 each.

Originated and Manufactured by Fairchild Bros. & Foster, NEW YORK.

Agents for Europe. Asia, Africa and Australasia:
Burroughs Wellcome & Co.,
LONDON, SYDNEY, CAPE TOWN.

Have you noticed that an injection or instillation of

## ARGYROL

(SILVER VITELLIN)

relieves the pain of local inflammation, while all other silver salts increase the pain? Moreover, scientific studies prove that Argyrol quickly destroys gonococci.

These facts explain why Argyrol is considered, the world over, a superior remedy in the treatment of gonorrhœa (injection of 10 per cent. solution every three hours) and other inflammations of the eye, throat, nose and ear (25 per cent. solution instillation or local application).

Produced by

## A. C. BARNES COMPANY

32 SNOW HILL, LONDON, E.C.

The following statement concerning

## OVOFERRIN

(IRON VITELLIN)

is a copy from the official records of the largest clinic in Germany where the remedy has been in continuous use for more than four years:

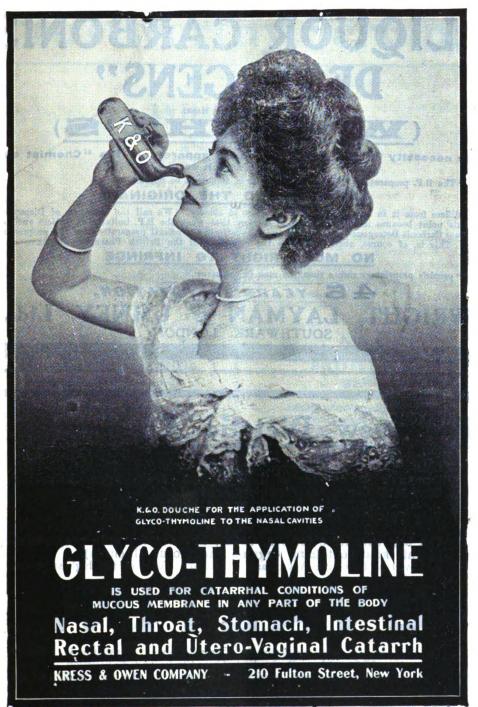

"Ovoferrin is an easily assimilable, well tolerated remedy which does not disturb digestion or cause constipation, but improves the appetite, digestion and general nutrition, and produces steady and progressive increase in the percentage of hæmoglobin and red corpuscles."

Ovoferrin is furnished by chemists, on prescription, in twelve ounce bottles. The dosage is one tablespoonful in a wine-glass of water or milk three times daily.

Produced by

## A. C. BARNES COMPANY

32 SNOW HILL, LONDON, E.C.

Sole Agents for Great Britain, THOS. CHRISTY & CO., 4-10 & 12 Old Swan Lane, Lendon, E. C.

Examined and approved by the Institute of Hygiene, 34 Devonshire St., Harley St., W., where this preparation can be seen, and its properties and value can be explained.

We ask the favour that Physicians will prescribe-

# "LIQUOR CARBONIS DETERGENS"

REGISTERED TRADE MARK)

### (WRIGHT'S)

The necessity for this request is made apparent in the "Chemist and Druggist," which says—

"The B.P. preparation (Liq. Picis Carbonis) is, it should be noted,

#### MUCH BEHIND THE ORIGINAL

and differs from it in composition, and therefore in efficacy. We call the attention of Dispensers to this point because it seems natural to suppose that when the B.P. imitates an article such as 'Liquor Carbonis Detergens' it is not immoral to substitute the official preparation for the proprietary one. This is, of course, absurd, because the compilers of the British Pharmacopoeia have

#### NO MORE RIGHT TO INFRINGE

other people's proprietary rights than the man in the street."

45 YEARS' REPUTATION.

WRIGHT, LAYMAN & UMNEY, Ltd., SOUTHWARK, LONDON.

## The New Dietetic Preparation.

OVALTINE is a dietetic preparation—in granular powder form—of high therapeutic value, made of Malt Extract, Fresh Eggs, Milk, and Converted Cocoa, and containing Active Lecithin.

Converted Cocoa, and containing Active Lecithin.

Extremely Nourishing and highly Restorative.

Very Palatable and acceptable to the most delicate stomach.

Simple to prepare.

The best substitute for Tea, Coffee, &c., and the only preparation of this kind containing Organic Phosphorus (Lecithin).

A powerful Digestive Agent and a Nervine Tonic of the highest order.

## OVALTINE

is the remedy par excellence in Convalescence, Neurasthenia, Faulty Digestion, Malnutrition, Brain Fag, Over Study, and Exhaustion. Readily assimilated and particularly adapted for the over-feeding of the Tuberculous. Suitable for infants, youths, adults, and the aged.

OVALTINE is packed in 4½ oz., 9 oz. and 18 oz. tins.
LITERATURE AND SAMPLE FREE TO MEDICAL MEN.

A. WANDER, Ph.D., Manufacturing Chemist, 1 Leonard St., City Rd., LONDON, E.C.

## Trustworthy Serums

"P., D. & Co."

### DIPHTHERIA

SERUM

in bulbs containing from

1000 to 6000 Antitoxin Units

independently certified as to

Purity, Asepticity and Potency by the Pathological Laboratory of the University of Cambridge.

"Standard" and "Special" Grades are supplied, differing only in the volume in which a given number of antitoxin units is presented.

For report of admirable results with "P., D. & Co." Antidiphtheria Serum, see Lancet, 29th Dec., 1902, p. 1685 :-"In some cases as much as 35,000 units were administered intravenously without untoward effect."

" P., D. & Co,"

### ISTREPTOCOC

SERUM (Polyvalent)

is obtained from the blood of horses immunised against

Puerperal Fever, Erysipelas, Scarlet Fever, Endocarditis, Pseudo-Diphtheria and other forms of Streptococcus Septicæmla.

In bulbs containing 10 c.c.

For report on the great value of "P., D. & Antistreptococcus Serum (Polyvalent), see British Medical Journal, 15th December,

1906, p. 1710:—
"I am convinced that without the Serum both patients would have died."

" P., D. & Co."

in bulbs containing

1500 Antitetanus Units of the standard adopted by the

U.S. Dept. of Public Health.

This amount constitutes one dose, the volume of which is about 10 c.c.

Each unit is capable of neutralising 1000 times the minimum lethal dose of tetanus toxin for a guinea-pig of 300 to 350 grammes weight.

See report on the effects of " P., D. & Co." Antitetanus Serum, Lancet, 8th April, 1905,

"Convulsions were well established before the Serum was injected. . The man was working within a few weeks."

These serums are prepared under the most rigid precautions by highly qualified bacteriologists in our own laboratories, which are officially inspected and licensed.

A Pamphlet entitled "Serum Therapeutics" containing an account of the preparation of these agents, and references to their literature, will be sent on request.

# Allenburys Foods

### Special Advantages:

- 1—The close conformity in composition of the Milk Foods to human milk; both fat and proteids being in similar relative proportions.
- 2—The readiness with which the Foods are assimilated; being as easy of digestion as maternal milk.
- 3—Their adaptability as an adjuvant to breast feeding during the period of weaning; no digestive troubles being likely to occur.
- 4—Their freedom from all harmful bacteria; being made from fresh milk, modified, evaporated at a low temperature, in vacuo, and preserved in hermetically sealed tins.
- 5—The ease and exactness with which the Foods can be prepared; the addition of hot water only being necessary.
- 6—Fresh elements of diet can be easily added to the Foods, and are specifically mentioned on each tin.

A reliable substitute is thus provided for the Mother's Milk, when this is wanting or deficient.

MILK FOOD No. 1.

MILK FOOD No. 2.

MALTED FOOD No. 3.

#### Notes and COMMENTS.

Poisons Schedule.

WE have never been much impressed with the new Poisons and Pharmacy Act, for not only was it the result of many compromises, but the Privy Council's own recommendations were

glaringly overridden in deference to the least desirable kind of trade interests. Now that the Act is on the Statute Book, any reform may be looked upon as shelved for the next decade or two at least. The absurdity of scheduling certain poisons whilst allowing patent medicines containing those poisons to escape was brought before the City Coroner's Court last week, in a case in which a woman was found by the jury to have died from an overdose of morphine taken in the preparation known as chlorodyne. There was some dispute about the actual cause of death, owing to the woman who was the subject of the inquest being a chronic alcoholic, but a toxicologist and the police surgeon were both convinced that the lethal agent was the morphine. There was a discussion as to the knowledge possessed by the public as to the composition of chlorodyne, and one of the medical men handed the Coroner a notice issued to chemists saying they were not to request purchasers of chlorodyne to sign the poisons-book, as that medicine did not come within Part I. of the Poisons Schedule. Comment on a law, especially a new law, which provides such loopholes, is surely superfluous.

Baby Smoker. THE medical inspector of the Oxfordshire Education Committee has discovered an interesting case in the course of his daily rounds. This is no less than a child not yet four

years of age who is suffering from "smoker's heart." The wretched little being is said to be supplied by his father with ten cigarettes a day, and to exhibit his accomplishment at local shows for the edification of gaping yokels. We are glad to learn that the Education Committee are We are going to hold an inquiry into the case, as not only are its pathological features worthy of investigation, but the conduct of the father, if what is said of him is true, is so inhuman that the Society for the Prevention of Cruelty to Children might well turn their attention to it. Dr. Kerr has already shown in his reports what effects cigarette-smoking may have on children, but we do not remember that any case of a mere baby has ever been brought forward in connection with tobacco-poisoning. The effect, however, is notoriously more marked in the young than in adults, and whereas large numbers of grown people habitually exceed moderation in smoking cigars without ill effect, a very few whiffs are generally enough for the most hardy school-boy.

In the instance under notice it would hardly be surprising if something more than temporary derangement of the cardiac action ensued.

Medical Motorists. MEDICAL men must not count on the precedent recently set by the Kingston Bench in the case of Mr. Stansfield Collier, the facts of which will be fresh in the minds of readers. A

Middlesex surgeon, travelling to Hampshire to an urgent operation, was timed by the police to be travelling in his motor at twenty-five miles an hour in the neighbourhood of Godalming, and was summoned to appear before the magistrates. gentlemen held that the safety of the public was of greater moment than the safety of a single person, and inflicted the usual fine. We confess there is a great deal to be said on both sides, and we should be the last to ask that unrestricted freedom should be given to medical men to travel at any rate they thought fit on the plea of professional exigency. Every case should be considered on its merits, but if a medical man can show that he is proceeding to a grave emergency, such as arterial hæmorrhage, poisoning, or obstetrical accident, and that he was not jeopardising the lives of others, we think that the Bench should consider such facts as providing a valid excuse for a reasonable excess of speed. Such cases are, happily, comparatively rare, and would only occasionally be brought to notice. The natural dislike of medical men to have to appear in the public court, to pay costs, and to lose valuable time, would be sufficient deterrents from abuse.

Reading for

WHAT is suitable literature for the sick? The question is suggested by the pronouncement of a medical man the Sick. that incalculable harm is often done to patients by reading "exciting and jarring novels." Especially to be condemned are

stories which "excite the imagination or leave too much to the imagination." We are all agreed that it is the height of unwisdom for patients suffering from heart disease to read exciting and jarring novels, but we cannot say that we think books which leave a good deal to the imagination are to be barred in all cases. The plea would seem to be one for "realistic" literature, which is generally a euphemistic term for a particularly unhealthy variety of novel. The authority quoted, however, does not leave us in doubt, for he plumps for "humorous stories written in a sentimental vein." The humorous stories that we know are not sentimental, and the sentimental are only humorous in their fatuity, with, of course, the immortal exception of Dickens. The sick, then,

would seem to be left nothing but Dickens, and as fashionable modern sentiment professes to find that classic as insipid as it pronounces Mozart's music, this reading would be as unpalatable to them as their broth and milk. Perhaps, after all, when a man is ill it is as well to let him read what he finds interesting, for not infrequently he finds devotional literature more to his taste even than humorous stories written in a sentimental vein.

A suggestive article appeared some weeks ago in M.A.P., a journal that **Empty** always speaks sympathetically of Pockets. the medical profession. It was written by the lady who writes the "Woman's Note-book," and is entitled "Working Pockets. for Nothing." At the outset she remarks that it would be easy to fill more space than that at disposal were she to write an article on "A Modern Doctor's Empty Pockets." Will doctors ever Will doctors ever strike? she wonders, and thereby repeats in essence a question that has vexed the medical world more or less pointedly for the past two generations. For what is a strike except the reduction to practice of a general organisation to reduce grievances? But the organisation is a necessary preliminary, and at present even the largest of our professional bodies has not placed upon its programme defensive protest, or, for that matter, even simple elementary defensive measures. When the strike comes-if we may judge from the signs of the times—there will be no lack of subjects to protest against, sweated contract practice, the competition of midwives and of hospitals, the existence of a non-representative and non-elective General Medical Council with full disciplinary and defensive functions, and the chaos of the many-portal system of qualifications. If medical men are to strike, these are only a few of the things they may legitimately strike about.

Telephone

M.A.P. deals with things within Consultations. her daily experience—and asks if the doctors will strike for fees for telephone advice? There are both men and women, she thinks, who are not only full of fear and anxiety of every sort for their loved ones at home, but who think it far cheaper—as, indeed, it must be-to ring up a doctor than to ask him to come round. Among other grievances, some of them obviously impossible to strike against, the

But the non-medical writer in

writer speaks of the necessity of appearing prosperous, of time taken up in unremunerative hospital work, of the "frauds" who seek hospital advice gratis, although able to pay for amuseof the doctor's friends who expect to be treated for nothing, of the charity cases thrust upon every medical man wholesale, and, lastly, of the week-ender at seaside hotels who departs on Monday without paying his fee. This list, by its very incompleteness and inadequacy, is interesting, inasmuch as it sets forth some of the drawbacks of professional life as they appear to a sympathetic journalist from the outside.

#### LEADING ARTICLES.

MEDICAL RESEARCH DEFENCE.—II.

THE extremely good and philosophical evidence given by Lord Justice Fletcher Moulton before the Royal Commission on Vivisection forms one of the not least important parts of the publications of the

science is not the bungling, haphazard sort of thing that the world outside believes it to be is pertinent to the last degree, although, at the same time it cannot be denied that a great number of scientific discoveries are, at the least, of vicarious, if not fortuitous, origin. It would be hard to find a better working definition of science as "common sense enlightened by appeals to actual fact, which are framed for the express purpose of giving you the information which is necessary for your common-sense to act upon." The realisation of this meaning throws a flood of light upon many phases of the subject. A man who experiments upon himself may be performing an heroic actionbut it may, nevertheless, be argued that he is a bad scientific man if he be driven to take such a course. The method that has hitherto yielded the most brilliant results has been to test theories and to ascertain fresh facts experimentally with the minimum of suffering to lower animals and without endangering human life. If the scientific man be impatient, he would like, perhaps, to experiment upon himself or upon other men, but if he be patient, there is no need that he should do anything of the kind. This attitude, of course, assumes that man has the same right over the lives of the lower animals that he claims for other purposes, such as that of food, of clothing, and even of the baser one of the mere provision of sport. Then, again, Lord Justice Moulton put very clearly the point which answers the unceasing argument of the anti-vivisectors, that the Act of 1878 has not restricted experimentation, inasmuch as the number of experiments since that year has increased tenfold. In order to arrive at the truth, a distinction must be drawn between really painful experiments and inoculations performed for diagnostic purposes, that is, to ascertain the nature of diseases in order that we might fight them. "The greater number of the experiments," he says, "have been inoculations, and as soon as the disease is developed the animal is killed, because what the experimenters have wanted to find out, aye or no, was what would the disease be under such circumstances? The number of cases in which you have to allow really painful experiments is confined to these-that is, the cases where you are examining the distant effects of certain lesions of the nerves, of interference with the digestive organs, in order that when you see symptoms which are so produced you may know where the evil is. They are never, I think, performed casually. The very painful ones would always, I should think, in the history of English research in physiology, be performed for some very definite object in order to give us this very essential knowledge." Turning next to a contribution by Professor Starling, of University College, we find a practical account of the use of dogs in scientific experimentation. It so happens that the dog is one of the few animals that can be kept in a healthy and normal condition in or near a laboratory, which, from the nature of the case, is usually fixed among populous surroundings. The dog is practically almost as omnivorous as man himself, while its organs are not too small to permit of experimental interference. Practically the whole of our knowledge Research Defence Society. His remark that I of the production of lymph in the body has been

derived from experiments upon dogs. This is owing to the fact that the main lymphatic ducts are "too small and delicate in the cat and rabbit to permit of a tube being placed in them so as to measure the lymph produced under any given circumstances. With the exception of some of the earliest observations made upon calves, our knowledge of the causation of the heart sounds, of the pulse, of the facts of blood pressure, has been derived from experiments upon the dog, the only animal of sufficient size obtainable for the purpose"; and to this Professor Starling significantly adds: "Further extension of our knowledge in these matters can only be looked for by continuing the experiments on dogs." Much the same may be said of the study of intestinal movements." Professor Schäfer's important experimental researches upon artificial respiration were carried out solely upon the dog, "since this was the only one of the laboratory animals in which the bony cage of the chest can be compared in any way with that of man." Then, again, the dog is the only animal fitted for an artificial gastric fistula, a condition that has yielded information of inestimable value to the physiologist, the pathologist, the physician and the surgeon. Professor Starling points out that, first of all, the operation involved is carried out under an anæsthetic; secondly, that wounds in man are not painful unless they become septic. By the terms of the certificate under which experiments are made, if the antiseptic precautions fail and suppuration occurs, the animal is required to be killed under an anæsthetic. The healed gastric fistula itself is painless. Even under these circumstances, we are practically prepared for Dr. Starling's emphatic statement: "Though I have been engaged in the experimental pursuit of physiology for the last seventeen years, I can say that on no ocasion have I ever seen pain inflicted on a dog or cat in a physiological laboratory in this country, and my testimony would be borne out by anyone engaged in experimental work in this country." In conclusion, a word may be said of the extinction of Malta fever, tersely described by Sir David Bruce, the distinguished discoverer of the specific microorganism, the micrococcus melitensis. It is due to experimental methods pure and simple that the disease has been eradicated and Malta converted from an unhealthy to a healthy station. During the past twenty years 14,000 or 15,000 British soldiers have been attacked in that island. A more triumphant vindication of experimental research it would be hard to find than that contained in the history of the extinction of Malta fever. But the publications of the Research Defence Society constitute one long series of similar vindications. It is well that experts, in reasoned thought and exposition, should be brought forward to inform the public with authoritative voice what are the answers to the charges of inhumanity which have for many years past been made against men of high aims and noble intellect engaged in the front rank of scientific warfare. Mr. Stephen Paget may be congratulated upon the share he has had in the organisation of the Research Defence Society upon lines that are, happily, not less defensive than educational.

DMMCTD ATION OF AN DOTTION

ADMINISTRATION OF ANÆSTHETICS. A MATTER of great public importance is raised by the Bill now before Parliament to regulate the administration of anæsthetics. The classes, apart from the general public, who will be chiefly affected by it are medical men, registered dentists, and quack dentists, and the principle involved is one deserving of the most careful consideration. Originally it was intended to enforce by Act that only registered medical men should be allowed to give general anæsthetics, but, owing to the opposition which would certainly be raised by dentists, the promoters have decided to put in a clause exempting them from the prohibition. Now, although anæsthetics may occasionally be administered to patients by medical quacks and bone-setters of one kind and another, we do not believe such practice is at all common, and consequently the Bill comes to be directed almost entirely against irregular dental practitioners. On the other hand, there is a strong party which would have registered dentists included in the ban, and a proposal to this effect will almost certainly be brought forward, so that we have to consider two points, namely, whether it is desirable in the public interest that registered dentists should be excluded from administering anæsthetics, and, further, whether dental quacks should be prohibited. The two cases stand on different footings. As regards the general question, there can be no possible doubt that, ideally, no person should be allowed to administer a general anæsthetic who has not been trained in clinical medicine and surgery. A dentist, per se, is not so instructed, his general medical training being purely theoretical, and specialised with a view to his future craft. Dentists, who are not also medical men, can have no scientific knowledge of the effects of an anæsthetic, and no rules, other than rules of thumb, to guide them in their administrations; whereas, not only are all the vital processes profoundly affected by the inhalation of an anæsthetic gas, but the clinical signs exhibited by the pulse, respiration, and so on, which are the sole guides of the medical man, can represent nothing concrete to a man who is not intimately acquainted with the clinical phenomena of the body in health and disease, and skilled in interpreting physical signs. Moreover, to cope with emergencies which arise during the time a person is unconscious from an anæsthetic demands readiness, resource, and surgical skill. The anæsthetist must be capable of judging whether the condition of disturbance is due to over-dosage, to cardiac or respiratory failure, to obstruction to the air-passages, or what not, and he must be prepared to inject strychnine, to give amyl nitrite, to perform tracheotomy, to do artificial respiration, or whatever is required, with promptness. On his judgment the fate of the patient hangs and the moment for successful intervention rapidly passes. Even the elementary precaution of examining a patient's heart before giving an anæsthetic cannot be undertaken without long medical training. People who talk about deaths under anæsthetics forget the number of deaths which are averted by withholding anæsthetics, by judiciously choosing the proper anæsthetic for patients in impaired health, and by the success of the anæsthetist's intervention

when emergencies arise, not to mention the thousands of cases in which the anæsthetist is warned by his observations of an impending change in the patient's condition, and adopts suitable precautions to prevent disaster. Now, as dentists, from the nature of their training cannot possibly possess this skill, it is obviously undesirable that they should be allowed to give general anæsthetics. It will be replied that they seldom give anything except nitrous oxide, that nitrous oxide is safe, and that if they are prohibited from giving it, medical men will have to be present at all their operations, with great consequent increase in the cost to the patient. We agree, and we agree also that the question is one for the lower middle classes and the poor who do not go to hospitals. Well-to-do people practically always insist on having gas from their own doctor, as it is. We are certain that no dentist should be allowed to give chloroform, ether, or, indeed, any anæsthetic except gas, but we think it ought not to be impossible to arrange that they were instructed in the use of gas, and allowed to give it, though we fail to see how they could be expected to cope with surgical emergencies, such as obstruction of the larynx, occurring during its employment. The Bill would practically give the coup de grâce to the quack dentist, and we do not think there are any reasons of public policy why his departure should be mourned. Temporarily, in poor districts, a certain dislocation would follow his disappearance, but competition being what it is, the fees of registered dentists would soon accommodate themselves to humble pockets, and the poor would be sure that those who practised on their mouths would not, through ignorance, commit the awful blunders which are far too common at the present day. The criticism of the Bill is meeting with at the hands of the lay papers is characterised by the usual gross lack of information which is associated in the lay mind with all things medical. Perhaps, however, the abysmal depths of ignorance were plumbed by an article in the Evening Standard of April 29th. In a leading article that journal set forth that twelve menths ago one of "our leading coroners" and a 'surgeon of European renown" came into collision on the question of holding inquests on persons who died under anæsthetics! That would be a bad enough blunder for one article, but the writer goes on to speak of a "sprinkling of dangerous quacks" being at the bottom of the medical pro-fession, who would be restrained by the Bill. If there are "quacks" anywhere in the profession, they would not be in the least affected. Sailing gaily on to defend the "unregistered dentist" (whoever he may be), the writer makes out that it would be hard on him and his patients if a qualified doctor had to be present when he gave an anæsthetic! As if any qualified doctor would be allowed to give an anæsthetic or countenance its administration by an unregistered man. But the gem of the article we have reserved to the last. We give it without comment, lest we impair its delicious confusion of ideas:—"It is a mistake to suppose that as an aid to the surgeon they (anæsthetics) first came into existence and use fifty years ago, when Lord Lister (sic) made his first amputation under ether at University College Hospital"! For the rest of the ridiculous nonsense set forth by our contemporary space fails us.

#### CURRENT TOPICS.

#### Escapes from Lunatic Asylums.

THE problem of the escaped lunatic is one that concerns the safety of the community, and its due consideration is the bounden duty of the State, in whom the care of lunatics is ultimately vested. The official attitude of the responsible authorities in the House of Commons must at times appear to the uninitiated outsider to be a trifle flippant and bureaucratic in dealing with a matter that is vital to the safety of the citizen. What guarantee is there that most lunatics who escape from asylums, and are not recaptured, are not of a dangerously criminal or homicidal tendency? Certainly the statistics given by Mr. Gladstone in the Commons a few weeks since are far from reassuring. The official figures relating to the escape of lunatics from asylums in England and Wales were as follows :-

Year.		Escaped.	Recaptured.	Still at large.
1904		367	327	40
· 1905	1	363	328	35
1906		396	349	47
1907		356	317	39
1908		364	308	56
Five years' aggregate		1,846	1,629	217

In answer to a further question, the Home Secretary replied: - "The Lunacy Commissioners consider, and I agree, that asylum authorities generally in the country take proper precautions to prevent escapes. As they state in the report which was presented to Parliament last week, public opinion would not endorse a retrograde step of making asylums once more in the nature of prisons." This hardly appears satisfactory to the taxpayer who has to face the consequences of the escape, both immediate and remote. As a famous writer upon social economics puts it, the Lunacy Commissioners appear to be thoroughly satisfied with the addition of one escaped lunatic per week to the free population, and to the subsequent multiplication of lunatics which follows. To differentiate between an asylum and a prison is surely to beg the question. Mankind has long ago decided that animals and lunatics require restraint in the best interests of the community. If restraint is to be efficient, it must be enforced and maintained just as stringently in the one case as in the other. Perhaps a departmental inquiry would help us to arrive at some conclusion with regard to the important question of escaped lunatics.

### The Taxation of the Motor-Cars of Medical Men.

A SHORT time ago we drew attention to the fact that the National Telephone Company, in their new system of charges, classified medical men in the same category as shopkeepers and business men generally, with the result that they were called on to pay a considerably higher annual charge for their telephones than were so-called "private" individuals. We are glad to think that our objections to such a course had some effect, and that the Company—in Dublin, at least—have not compelled medical men to change from an unlimited to a measured rate system. We now take the first opportunity of directing professional attention to one of the proposed clauses of the new Budget,

whereby a tax of three pence per gallon is to be imposed upon petrol. As at present proposed in the case of "commercial users" and motor-cabs, a remission of half this sum will be given. We have, however, some fear that while the Telephone Company, for the sake of an increased revenue, classified medical men as "commercial," the Government, with a similar object, will classify them as "private." If, however, a united demand is presented by the medical profession for the right to obtain petrol at the commercial rate, we have no doubt that it will be successful. As to the wisdom of the tax in general, we say nothing, except that we should like to be able to forecast the opinions of posterity on the action of the Government in hampering, by taxation in its childhood, a mode of locomotion which, if unhampered, promises to be of universal application in the near . . .

Mental Obliquity.

A CORRESPONDENT has sent us a copy of a most curious article on fevers which he has apparently contributed to the columns of a local paper, and which he requests us kindly to reprint. We regret we are unable to comply with his request, but we gladly notice his production, because it affords a curious insight into the popular mind, which is so prone to suffer fools gladly. The article begins with the statement that "truth and error, fact and fiction, cannot occupy the same place in thought. . . . There is thought that enters easily, thought that enters with difficulty, and thought that never enters at all." The writer then proceeds to inform his readers that "after thirty years of hard work and stern thought, I have evolved my nerve current theory... This theory implies that the vital force is a fluid which circulates through the system by means of the nerves, in the same way that the blood circulates by means of the veins." Starting with this theory, he then proceeds to elaborate his "theses on illness." This "theses" consists of some fifteen dogmata, the essence of which is that "the circulation of the vital fluid by means of the nerves is the true key to the knowledge of the nature of disease," and that "this discovery is more important and far-reaching than Harvey's discovery." Although each "thesis" might form the heading of a distinct chapter, the writer is conscious that the editor will "cut him short," and accordingly he abandons his dogmata, and proceeds to the discussion of fevers! "A fever is a rumpus. It is the vital force making a desperate effort to expel the excrementitious matter from the system. It is a sign of health. We ought to rejoice to see a fever." "There are almost no fevers to-day, and chronic diseases are rampant." This is the writer's "saddest reflection." Hence the presence of sickly children in our schools and the degeneration of the race. He concludes his article with the sigh, "Oh, si sic sil." Surely none but a most matter-of-fact editor could have omitted the last two letters, which are so very obvious. In later articles the writer proposes to tell us how to substitute fevers for chronic diseases.

#### PERSONAL.

DR. JOHN SHEPPARD has been appointed a Justice of the Peace for the Borough of Dublin.

DR. LYTTON P. MAITLAND has been appointed Medical Registrar to Charing Cross Hospital.

THE British Balneological and Climatological Society will hold its annual provincial meeting this year at Torquay, the date being fixed for Saturday, May 8th.

THE next session of the General Medical Council will open on Tuesday, May 25th, when the President, Sir Donald MacAlister, K.C.B., will take the Chair at 2 o'clock, p.m.

THE Right Hon. Lord Viscount Duncannon is to preside at the Festival Dinner in aid of the funds of the Metropolitan Hospital at the Whitehall Rooms on May 20th next.

SIR CHARLES BALL, Regius Professor of Surgery in the University of Dublin, will deliver a special lecture on "Cancer of the Rectum" before the Post-Graduate Class to be held early in June.

At the meeting of the Therapeutical and Pharmacological Section of the Royal Society of Medicine yesterday Dr. Hale White and Dr. Eyre opened a discussion on the subject of "Vaccine Treatment."

DR. E. W. HOPE, the well-known Medical Officer of Health for Liverpool, has been presented with a handsome testimonial by the members of the Municipal Sanitary staff on the attainment of his silver jubilee in the service of the Municipality.

LORD SANDHURST, treasurer of St. Bartholomew's Hospital, has received from Mr. Henry T. Butlin, D.C.L., F.R.C.S., £100 towards the pathological block, being a third donation of that amount to the rebuilding fund of the hospital.

At a provincial sessional meeting of the Royal Sanitary Institute, which will be held at the University of Birmingham on Saturday, May 8th, a discussion on Tuberculosis and the Milk Supply will be opened at 11 a.m., by Mr. J. Malcolm, F.R.C.V.S., Veterinary Superintendent to the Birmingham Corporation.

THE Hon. Harriet Le Poer Trench, who left estate valued at £122,769, bequeathed the net proceeds of the sale of valuable personal articles to the Hospital of St. Elizabeth, St. John's Wood, and on the falling in of certain annuities the capital is to be paid to the hospital, her intention being that the bequest to the hospital shall amount to £10,000.

MAJOR F. J. W. PORTER, R.A.M.C., appeals for funds in aid of the Princess Christian Mission Hospital at Sierra Leone, which was totally destroyed by fire on March 17th. Owing to the heroism of Miss MacPherson, one of the nursing sisters, no lives were lost, but the European and native sisters had the whole of their effects destroyed. Subscriptions may be sent to Mr. F. Fishwick, honorary treasuren, Sierra Leone Diocesan Fund, 20 Harold Road, Upper Norwood, S.E.

THE Ninth Annual Dinner of the Medical Graduates' THE Ninth Annual Dinner of the Medical Graduates' College and Polyclinic will be held at the Trocadero Restaurant, Piccadilly Circus, on Monday, May 24th, at 7.15 for 7.30 p.m., when Professor Howard Marsh, M.A., M.C., F.R.C.S., Professor of Surgery in the University of Cambridge, will preside. During the evening a presentation will be made to Captain A. E. Haward Pinch, late Medical Superintendent of the Polyclinic. The price of the dinner, 7s. 6d. (exclusive of wine) will be collected during the evening.

### A CLINICAL LECTURE

#### THE DIRECT OR INDIRECT EFFECTS OF SURGERY OR SURGICAL LESIONS IN MENTAL OR NERVE DISTURBANCES.

By WILLIAM ALEXANDER, M.D., F.R.C.S.,

Hon, Surgeon, Royal Southern Hospital, Liverpool; Lecturer on Clinical Surgery, Liverpool University.

THE influence of the different states of health or well-being of the various organs of the body on the mind is admitted by everyone. The genial influence of a comfortable dinner, the mental irritation produced by want of one, or by an indigestible meal, the angry feelings and violent expressions which often angy reenings and violent expressions which often accompany gout, the misery of toothache, ear disease, or neuralgia, the despondency born of constipation or liver disease, and the acute delirium of fever or of sepsis, are only a few of the most common phenomena that with many others lie within the observation not only of the trained observer, but also of the man in the street. We have heard of people being driven out of their wits by tickling, and the delirium at the period of the greatest distension of the cervix uteri or perinaum is really a short madness produced by the severity of the symptoms. The last days of inoperable cancers of the tongue and of the breast I have several times seen clouded by a marked attack of delusional insanity, and I can recall several operations where with a normal pulse and temperature the patient was quite insane for some days after the operation, and I can also remember two where the patients died in consequence of the exhaustion produced by the mental disease and by the impossibility of satisfactorily feeding the demented patients. These are general, well authenticated cases about which we are all agreed, but the cases which I wish to bring before you today are not these general cases. to bring before you to-day are not these general cases, but others where disease either functional or organic, of a solitary organ or of a definite part of the body produced symptoms of insanity, mostly of the delusional type, and where the removal of the disease cures at the same time the insanity. I shall first of all briefly relate the cases, then distinguish them from other nervous cases where operation should not be performed, and finally point out to you the dis-tinguishing features of the class of cases where I think

tinguishing features of the class of cases where I think operations are likely to be beneficial.

CASE 1.—Twenty years ago I excised very extensively the left knee-joint, for advanced tubercular disease, of a man, at. 25. After operation the limb was firmly fixed in an arrangement of Thomas's splint and plaster-of-Paris that allowed free access to the knee and at the same time maintained. to the knee and at the same time maintained perfect rest of the limb during each dressing. These dressings had to be done daily on account of the septic conditions of the parts operated on. The pulse and temperature kept satisfactory all through the course of the case, but five days after the operation the patient became "insane." Each morning he would describe imaginary morning trips to the local market extensive became "insane." Each morning he would describe imaginary morning trips to the local market, extensive purchases of cattle there, the friends that he had met and the conversations he had had with them. He enjoyed telling me about these trips of his, talked with vigour and intelligence, and laughed at the funny parts in a perfectly natural and apparently rational manner. With the nurses he was lively, pleasant, and full of the same delusions, which he would describe to them in the same circumstantial way which he did to me. He never complained of any pain, and there to me. He never complained of any pain, and there was no evidence of any undue pressure. A fortnight after the operation I took down the limb and found a small pressure sore of the size of a shilling on the heel. While I was taking the plaster off he told me where he had been that morning. Next morning when I visited the patient all the delusions had completely disappeared, and he was surprised and puzzled at my questions in reference to them. He only remembered them as the shadowy figments of a dream. It may be said that the intolerable agony of the constant

pressure upset the mental balance in this case. of that agony there was no evidence. He seemed to be, and always said he was, comfortable, and there was no indication of discomfort at any time. It must have been some peculiar mysterious result of the pres-

Insanity is rare from pressure sores. This is the only example I have met with where any mental symptoms occurred, and I have seen a good many

pressure sores in my time.

We could not say how long it was after the removal of the splint before his mental balance was restored. It was only next morning that my questionings found it out. No other change had occurred in food or medicine, the only change was the removal of the pressure on the heel.

CASE 2.—In November, 1907, a boy, æt. 14, the subject of a swing-boat accident, was admitted under my care suffering from a depressed fracture of the skull. The depression was situated a little to the right of the middle line and two inches in front of the occipital protuberance on the right side. The boy on admission was confusedly maniscal shouting incomplete the state of the s admission was confusedly maniacal, shouting incoherently, rolling out of bed in a sub-conscious state, with flushed face and suffused eyes. He had no temperature. The accident had occurred three days before he came under my care, and he had been taken to a neighbouring hospital on account of the cerebral symptoms. The father said he was advised to have the boy sent to a lunatic asylum, as no operation could be performed until he became calm and rational. could be performed until he became calm and rational. The night of his admission to my wards I operated and raised the depressed bone, a sharp-pointed piece of which had penetrated the superior longitudinal sinus. By raising the head and packing the wound firmly with double cyanide gauze, serious hæmorrhage was effectually prevented. The boy was quite rational next morning, and remained so during his convalescence, and we know he has continued well, as we have seen him frequently until quite lately, i.e., six months after operation. six months after operation.

REMARKS.-I removed the depressed bone immediately because it was manifestly pressing on the brain and was the probable cause of the mental excitement. My predecessor in the case did not perceive any causal connections between the mental symptoms and the traumatism, and advised asylum treatment before operation. It is quite likely that the cerebral symptoms would have subsided under expectant treatment, as the brain would in time have become accustomed to the new condition of matters, but the short and straight course was, it seemed to me, to remove the offending body, when the cerebral symptoms would probably disappear of themselves. The boy was quite sane till the bones of his skull were crushed in, then he became maniacal. The bones were removed from their depressed position, the brain rose to its original position, and the mental dis-

turbance disappeared.

CASE 3.—In the beginning of May, 1899, nearly ten years ago, I was asked to see a young lady, æt. 26, with Dr. Gill at his asylum at Formby. The case was one of delusional insanity with suicidal tendencies. Her father had died by his own hand. The object of my visit was to ascertain if the patient suffered from any uterine disease, as was alleged by her friends, the cure of which might relieve the mental condition. We examined the patient under an anæsthetic, and found that she was suffering from a marked retroflexion of the uterus, which had probably existed for a long time. We were told that the patient

had complained of pains in the back, and "bearing down" for some years. After considering the case carefully and anxiously, we agreed to recommend operation. Both the patient, who was fairly lucid at the time, and her mother were pleased to find that something was wrong that might explain the disturbance of the mental state, and preparations for the operation were at once made, and the operation of shortening the round ligaments was performed in the asylum. It was quite successful in every way. The It was quite successful in every way. wounds healed by first intention, and the state of the patient's mind gradually became quite natural and sane. About three months after the patient was dis-charged cured. She has remained well ever since, and has been actively engaged in work that occupies and tries all her faculties. The alternative of operation was treatment by pessaries, and at the time of the examination we had pessaries ready for insertion; but we preferred an operation on the ground that it would be better to avoid instrumental treatment that might, and probably would, require frequent manipulation, and to advise a treatment whereby the dis-placement would be cured once and for ever. The result in this case equalled our highest hopes, and the length of time since the operation shows that the good results have not been ephemeral.

Case 4 occurred in an epileptic woman, æt. 32, who had been a confectioner until the onset of fits compelled her to give up work and take refuge in the epileptic colony at Maghull. Here she showed signs of increasingly severe attacks of menorrhagia accompanied, and sometimes followed by periods of such extreme irritability and violence towards her companions, that her mother was at last called upon to remove her daughter from the colony. The poor woman was in great distress. She could not keep her at home as she was afraid of her; she disliked the idea of sending her to a workhouse, and the patient was so sensible and affectionate in the intervals of her irritable state that she could not think of abandoning her to such surroundings or to those of a lunatic asylum, which we feared would be her final home at no remote period. She was advised that the mental condition was probably due to the state of the endometrium, and that if this were cured, the hæmorrhages stopped, and the state of anæmia corrected, the mental condition would improve so that we might be able to retain the patient at Maghull. Curetting had already been performed several times without any permanent good effects, and ergot and other remedies had been tried in vain. The only certain remedy was hysterectomy. This would stop the menorrhagia effectually, and the question of marriage need not be considered if the mother and child were both willing. The continuance of the race through the patient would not, under any circumstances, be advisable. Both mother and daughter not only consented, but begged that the operation should be performed. The operamother and daughter not only consented, but begged that the operation should be performed. The operation was successfully performed by the abdominal route twelve months ago. Since the operation the patient has improved very remarkably, not only as regards her physique, but her mental condition is so much improved that she is now a good colonist and lives at peace with her companions. She is receding rapidly from the borderland of insanity.

CASE 5.—A lady, et. 55, was troubled with intense intercostal neuralgia on the right side, so intense as to induce a melancholic condition and to cause the patient to cry out frequently and become bathed in tears. She had a diffused fatty tumour located in the

patient to cry out requently and become bathed in tears. She had a diffused fatty tumour located in the interscapular region on the affected side, and this tumour, in my opinion, was the cause of the neuralgia, and the best treatment was, from any point of view, obviously the removal of the lipoma. The patient did not like the idea of an operation, and being in London she consulted a recognised authority of the very highest position, who informed me by letter that the neuralgia was, he believed centric in origin, due to some obscure affection, probably of the posterior spinal nerve roots or of the spinal cord. The fatty spinal nerve roots of of the spinal reverse roots. He had never seen such tumours produce pain, and he prescribed a nerve tonic, containing arsenic, to be taken for a long time. Several other opinions were obtained, all practically agreeing with this. Well, I

said to the patient, I must bow to the weight of authority, and your best plan will be to take the medicine regularly as directed; but, I said (it was now July) "if at the end of the year you are still in despair, if you come to me again I will have no hesitation in removing the tumour." In November she came back and said she placed herself in my hands, that her condition was no better and was intolerable. that her condition was no better, and was intolerable, and that if I still thought the operation likely to cure her she was prepared to undergo it. The operation was performed on December 30th, 1891. About half a pound of fatty tumour was removed from the back, the aponeuroses and fasciæ over and between the dorsal muscles had to be opened up to allow of the removal of masses of fat that had penetrated the muscular interspaces, and had burrowed in all directions. I was rather appalled at the unexpectedly large gap that I was compelled to make before the whole tumour was removed and feared the immediate result of such an extensive dissection as was found to be of such an extensive dissection as was found to be necessary. However, the shock was not severe, and the wound healed quite satisfactorily. On the fifth morning when I visited the patient I found her in tears. She said she was "just as bad as ever," and that I was wrong in thinking the tumour had anything to do with the neuralgia. I asked her to give me a short time longer before my practice was quite condemned; that we had disturbed the nerves a good deal, and that we could hardly expect them to settle down so soon. She agreed to keep up her spirits for down so soon. She agreed to keep up her spirits for another week. On the 7th day, i.e, two days after, she received me with a radiant face, saying that she she received she was losing the neuralgia, and that I was right after all. To make a long story short, she was quite cured of her neuralgia, and remained well until her sudden death from cerebral hæmorrhage seven years afterwards.

Now, gentlemen, these cases offer some instances, which I could add to if I searched my notebooks, but they are sufficiently varied to represent several classes

of disease.

(1) The mysterious effects of pressure on the heel in producing insanity, and its immediate cure when the pressure was removed.

(2) The direct effects of a depressed fracture of the skull on the onset of acutely maniacal symptoms and the immediate relief through the elevation of the depressed bone.

(3) The presence of a retroverted uterus in a case of delusional suicidal insanity, and the good effect of the cure of the displacement on the insanity.

(4) The baneful influence of metrorrhagia on the

mental state and the probable rescue of the patient from a lunatic asylum by operation.

(5) The failure to connect as cause and effect a lipoma of the back and intense intercostal neuralgia, and the complete cure of the patient by operation.

You will find gentlemen, as you engage in the work of your profession that the above cases are rare, and that there is a large amount of scepticism amongst medical men as to the connection between the alleged operations and the accompanying nervous or mental operations and the accompanying network of mental disease. Some ladies who were acquainted with the history of the Case No. 3, had a relative similarly affected, and believed, whether rightly or wrongly, that she had also a uterine displacement. They tried that the displacement of the displacement of the control of the displacement of the control of their utmost to have their suspicions verified or disproved by a vaginal examination, but it was impossible; the opinions of the medical attendants (specialists in lunacy) were so strongly against the possibility of such a condition that the patient was enabled to commit suicide without any examination having been made to find out her condition. The reason is that we know so little about the nature and causation of mental disease that, to use a term from the billiard room, such cases as I have described are put down as "flukes," and you know that flukes are not to be reckoned on as regular occurrences. Uterine displacements, as a rule, occur without mental disturbances, pressure sores rarely produce delusional insanity, and a depressed fracture of the skull does not often produce acute mania, although I have met with several cases where it did. It is not, however, the general experience.

Pure physicians generally look upon such people as neurotics, and talk about the mysteries of hysteria and neurasthenia.

Many years ago a bright little woman was brought Many years ago a bright little woman was brought to me suffering from severe pelvic pain, enlarged ovaries and retroflexed uterus. The displacement was corrected, and change of scene obtained, but without any improvement. A physician was called in, and the disease declared only neurasthenia, and a proposed exploratory laparotomy was negatived, the statement being made that if the woman was left alone she would be all right. Eleven years after she called on me, bringing another patient, and I had an opportme, bringing another patient, and I had an opportunity of ascertaining her condition. The pain in her pelvis and back was worse, but she dare not complain as her husband immediately thought she was malingeras her husband immediately thought she was malingering, and would not allow her to see any doctor. She did not call down "blessings" on the head of that physician, whom she looked upon, and rightly, as the bane of her life and the cause of her misery. Now, many cases apparently somewhat similar to those I have described to-day will be found amongst the hysterical or neurasthenic people with unstable nervous systems, who are likely to be upset by apparently trivial causes. Such people are often very fond of operations, and sometimes desire very serious operations to cure their symptoms, and sometimes a skin wound does just as well as the full operation and occasionally cures the patient of an imaginary pain or of an imaginary disability. These are quite different of an imaginary disability. These are quite different to the cases I have described, and are rarely benefited by operative treatment. One remarkable case of this neurasthenic kind was seen by me nearly twenty years ago, where the patient, a male, æt. 30, about to be married, complained cf great pain in a varicoccele. This I operated on in the usual way, and he was quite comfortable till the wound healed up. Then the pain returned as before, and he went to another surgeon, who took away some veins from the inguinal canal. This succeeded till the wound again healed. He went to another surgeon, and had the whole tract of the cord cauterised with the same final result. After a varied experience during ten years of surgeons by operative treatment. One remarkable case of this After a varied experience during ten years of surgeons in Liverpool and London he returned to me, and I cut down on tender points with immediate, but temporary, relief, until at last I refused to cut him any-

where again.

Cases like this you should avoid meddling with. This man blamed us all in turn and described the mistakes that each of us made, the last operator being for the time the scapegoat for the sins of all the others. The first operation for varicocele was the only legitimate one; the others were unnecessary and harmful. Another case, male, æt. 40, whom many of you may have seen in my wards, complained of intense pain in the left groin and testicle of such an agonising nature that he could not work at his trade as a joiner without "tremendous" discomfort, and yet he said he must work as he had an old mother depending on him. Recognising the neurotic nature of his pain I advised him to continue work, as it was, to my mind, his only hope, and gave him nerve tonics and encouraging advice if he fought on in spite of the

Whether by his own fault or no, he was thrown out of work, and he begged me to take him into hospital and do something for him. The glands in the left groin were somewhat enlarged, although there was no question of syphilis in the case; and when he was admitted to hospital I removed them, in the hope that the moral effect of the operation would be beneficial. He was very restless after operation and displaced the dressings a good deal, but in spite of this the wound healed up in a fairly satisfactory way. Imme-diately after the operation the pains that he said he had suffered before operation dwindled into insignificance, and he commenced to describe the terrible pains he now suffered on account of the operation, blamed me for doing it, and talked about the healthy, painless state he was in before he was touched. We showed him the notes recording in his own words the "terrible symptoms" he said he suffered from before the operation as a proof that at the worst we had only failed to relieve him. It was no good, we had to refuse to see him any more, and the last time I heard about him he had settled down into his old condition and had gone to work. The less you have to do with such cases the better.

In regard to the five cases reported as being so say, in the first place, that the condition of the patients was beyond their control. The condition was not imaginary, but insanity, mania, intense neuralgia along distinct nerves and always there, not described with a placid, smiling face, but with the patient writhing in agony, not talking about agony, etc.

In the second place, the operations were undertaken for distinct diseases, and such as would be undertaken in a healthy person. The removal of the splints for the small abrasion on the heel was not undertaken to cure the insanity, but done in the ordinary course of surgery; the shortening of the round ligaments for an acute displacement was a thing to be done for its own sake, although it was undertaken in the hope that the mental state might be relieved thereby as well as to relieve the discomfort of the disease. The elevation of a depressed fracture of the skull was the proper treatment for the traumatism of the head, the removal of the large fatty tumour was the thing to do, irrespective of the neuralgia, and the hysterectomy for the diseased uterus, that had several times brought the patient to the brink of the grave through hæmorrhages was a sound operation, irrespective of the mental con-dition of the patient. The pathology and atiology of mental diseases is still obscure, and we cannot tell what influence lesions of the body may have on the My cases seem to me to show that if there is a distinct disease that ought to be treated in an ordinary sane individual, and if that disease occurs inter-currently with mental disturbance of unknown causation and of an acute character, then I say that distinct disease should be treated, and can be treated successfully, notwithstanding the mental condition, and with the hope that the mental symptoms may also be cured.

This advice is different to the usual practice where the operation is often postponed till the mental condition improves, but the cases I have given, and similar others that I could give, plead strongly for

my opinions.

The nursing arrangements in these cases must be very complete and effectual to prevent any mishap in the after treatment of such cases, and they should not be undertaken unless sufficient help and supervision are available.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by John O'Conor Donelan, L.R.C.P.I., L. R.C.S.I., Resident Medical Superintendent to the Richmond District Asylum, Dublin. Subject: " Alcoholic Insanity."

#### ORIGINAL PAPERS.

#### OATMEAL IN THE CURATIVE TREATMENT OF DIABETES MELLITUS. (a)

By PROFESSOR CARL VON NOORDEN, Director of the First Medical Clinic in Vienn

At the Congress of the German Scientists held in the year 1002 I gave for the first time a report about oatmeal cures in the case of diabetes mellitus. I had gained the experience that many diabetic patients had gamed the experience that many discrete parties had borne the diet of oatmeal very well, so that we could give them great quantities of the same, without causing glycosuria, while all other carbohydrates brought on excessive sugar secretions. Indeed it was possible sometimes under the influence of catmeal (50 grammes a day and more) to cause the sugar to dis-

<sup>(</sup>a) Abstract of Paper read in Professor Noorden's absence before the Indian Medical Congress, Bombay, Feb. 1909.

appear altogether, where the strictest diet, perfectly free from carbohydrates, did not render the unine perfectly free from sugar. It seemed even as if in such severe cases the oatmeal had a more favourable effect and was borne better than in slighter cases of diabetes. These experiences as to the effect of oatmeal were quite paradoxical, i.e., they seemed to contradict all former experiences as to the influence of carbohydrates on diabetes mellitus. One must remember that 250 grammes of oatmeal contain not less than 180 grammes to 190 grammes of pure starch.

In the 6½ years since my first publication a number of communications on the subject from other authors have appeared. Most of them endorsed my opinion entirely, others differed from them. I can perfectly well understand that some of these writers arrived at unfavourable results, for firstly it is absolutely necessary at the commencement of an oatmeal cure to keep strictly to definite rules, acquired by experience, and this was not always the case with those who had had bad results. And secondly I have myself pointed out from the beginning that only a small portion of diabetic patients are benefited by the oatmeal cure, while the majority are unfavourably influenced by it. He who has only to do with single cases will, for this reason, never be able to form a correct opinion.

Since I made a trial of the catmeal cure for the first time in the year 1899 I have treated 2,000 cases of diabetes for weeks in my public and private clinics. In the case of 400 of these patients the oatmeal cure was applied, and I am now in a position to give a definite judgment as to the practical value of the same, although we are still far from being able to offer an explanation of this enigmatical result.

#### METHOD OF PROCEDURE.

I will next explain my method of procedure in the oatmeal cure:—It is absolutely necessary before beginning the oatmeal cure to cleanse the urine entirely or almost entirely from sugar. This is done by restricting the patient for some days to the usual diabetes diet of absolutely no sugar and no starchy foods. If by this means they are still not free from sugar, as sometimes happens in severe cases, the patients must have two "vegetable days." The food consists on these days of the following elements:—

Tea, coffee (without additions), meat broth, made from beef, veal, mutton, or chicken, five whole eggs (hens' eggs) and five yolks of eggs, fresh vegetables as spinach, green salad, cucumbers, tomatoes, cauliflowers, asparagus, sauerkraut, etc., butter, bacon, marrow of bone—oil, lemon, vinegar, mineral waters, ½ bottle of claret, 1 or 2 small glasses of cognac or whisky.

One finds in the severest cases that small quantities of sugar remain in the urine. Sometimes the aceton-bodies increase.

The oat cure consists in the daily administration of 250 to 300 grammes of oatmeal, best given in the form of gruel or porridge, every 2 hours, 200 to 300 grs. of butter, and about 100 grs. of vegetable proteid or 8 eggs may be taken in addition. Most of the patients prefer the eggs. Nothing else is allowed except black coffee or tea, lemon juice, good old wine or a little brandy or whisky. In many cases you will see that these large quantities of oatmeal agree excellently with the patient and that either no sugar at all or only 20 to 30 grs. can be found in the urine, this shows that far the largest quantity of carbohydrates of the oatmeal have been assimilated.

After the 3 oatmeal-days it is absolutely necessary to let 2 vegetable-days follow; should the urine not have become sugar-free during the oatmeal-days, it will become so in pearly all cases.

will become so in nearly all cases.

It is exceedingly useful then to let again 3 oatmeal-days follow at once, upon which 2 vegetable days should succeed.

Now only may one begin to let slowly other foods be added to the foods which are allowed on the vegetable-days. One may best try with an addition of fish 200 to 300 grammes, and only when the proof has been given, that fish does not let sugar reappear in the urine, some meat may be taken. In severe cases,

however, this should never be more than 200 grammes weighed cooked. Later on, cheese and cream are allowed. Now the patient has again arrived at a diet, which is called the ordinary strict diabetic-diet. One will notice, that he now with this diet eliminates much less sugar, and that the quantities of aceton are much smaller than they were before the oatmeal cure began. It is then allowable to try small quantities of other carbohydrates (bread, potatoes, and others).

PRACTICAL RESULTS.

My practical experiences are the following:-Amongst about 400 patients upon whom I tried the oatmeal cure I gained excellent results with 28 per cent. that is such results as can be compared with the above example. The best results were gained with children, young men and women and grown-up people to about 40 years old. For older diabetics the oatmeal cure is not so suitable, although I had some good results with people between 50 and 70 years of age. For the best results were obtained in medium cases. Very severe and quite slight ones are not suitable for this cure. Diabetic patients with nephritis should on no account be exposed to the catmeal treatment, because mostly ædema results which only disappears slowly. Often the oatmeal produces strong diarrhoea. This can be prevented by ordering tincture of opium during the cure, which will make the diarrhoza disappear at once (5 times a day 5 drops of tincture of opium). Such patients who suffer from bad secretion of the pencreatic gland may not undergo the oatmeal treatment. They would acquire severe fatty diarrhœa (steatorrhœa), which leaves them weakened.

The good results of the cure will always fail to come, as soon as other carbohydrates are added to the oatmeal, and it is also disadvantageous to add meat, or extract of meat, or meat broth, or casein, plasmon and other foods of this kind. Should diabetic coma threaten there cannot be found a better means to avert the danger of the auto-intoxication than the catmeal cure. In such cases it is most important to cause the re-sorption and assimilation of as many carbohydrates as possible. Next to this of course alkalines must be supplied.

The oatmeal treatment cannot cure the diabetes mellitus, but it can considerably diminish its danger. It is of the greatest importance that from time to time the patients should assimilate large quantities of carbohydrates. Thereby the danger of acid poisoning is averted. For this reason I prescribe, in such cases, in which the treatment has turned out well, a repetition of the oatmeal cure 4 or 5 times a year. The cure always takes one week as follows, that is, 2 vegetable days, 3 oatmeal days.

One often has technical difficulties in accomplishing the cure, and it is nearly always impossible to achieve good results if the patient undergoes the cure the first time in his own home. I therefore always insist upon his undergoing the treatment for the first time in a hospital or in a sanatorium. As soon as once he has learned how to behave during the oatmeal-days, the later cures can easily be undergone at home.

EXPLANATION OF THE RESULT.

It has been said, that the results of the oatmeal cure depend upon the diminution of the proteids; one knows, that diabetics often stand more carbohydrates when taking only few proteids, than they do when taking many proteids. But this interpretation is wrong. The results of the cure are the same, if roo gr. of vegetable proteids or 8 eggs are added—even more eggs could be allowed, but meat would disagree. It has been said that glycosuria does not result from oatmeal, because the starch of the oatmeal ferments in the intestinal canal and that consequently only fatty acids and no carbohydates are resorbed. But this objection is wrong; for the composition of the fæces is in far the most cases quite normal; moreover the decrease of aceton proves with certainty the resorption and assimilation of carbohydrates.

I previously thought and taught that the particular nature of the amylum, which oatmeal contains, was the reason of its good assimilation. It is known that some carbohydrates agree better with diabetic persons

than others, such as lactose, which is better tolerated than ordinary sugar and all the other ordinary amyloses. We have tried to prepare the starch of the oatmeal quite pure and to compare its effect upon the diabetic patient with the starches of various other substances (from wheat, rye, potatoes, etc). But the pure starch of oats acts just as unfavourably upon the glycosuria as other starch does. However, it is sure that the starch, when prepared pure, undergoes certain alterations in its chemical constitution. Possible it is that the starch of oats in its original constitution possesses quite different qualities than the pure oat starch, and that, indeed, it agrees better with the diabetic than other starches. Latterly our attention is directed to the fats of the oat. We found that the alcoholic and etheric extract of the oat contains substances of very great and toxic power. If you give to a small dog a subcutaneous injection of 1 gramme of concentrated oat-extract, which contains the fats and the lipoids, the animal dies paralysed in 24 hours.

#### EXPERIMENTS ON ANIMALS.

We caused artificial glycosuria in dogs by injection of adrenalin. When, at the same time, we injected a small quantity of oat-extract, no glycosuria arose. As there is no doubt that the adrenalin diminishes the internal secretion of the pancreatic gland, the probability arises that the oat-extract has the opposite effect, *i.e.*, that the extract is a stimulus for the pancreatic secretion. After extirpation of the pancreatic gland in animals, the oatmeal treatment has a very bad effect, and also the oat-extract does not diminish the glycosuria. Also this seems to prove that the oat-extract only acts by influencing the internal pancreatic

secretion in a direct and specific manner.
You must acknowledge that these experiments give a good prospect for the treatment of diabetes in men. a good prospect for the treatment of diabetes in men.
Until now we did not dare to administer the oatextract in cases of diabetes, because all the extracts which we prepared were eminently poisonous;
but, of course, the experiments are continued. We
hope to gain such extracts of oats, which are not so
poisonous, but which produce the wished-for good
effect upon glycosuria.

As we see things to-day, we presume that the astonishing effect of the oatmeal treatment is due to the circumstance, that with the oats we introduce into the body small amounts of a substance which acts as a stimulant upon the internal secretion of the pancreatic gland. Why this good effect only is met with in certain cases and missed in others we cannot yet tell.

#### THE TREATMENT OF GONORRHŒA IN GENERAL PRACTICE.

By J. EDWARD McCRACKEN, L.R.C.S.I., Honorary Surgeon to the Liverpool Hospital for Cancer and Skin Disease.

THE internal remedies for the amelioration of the discomforts attending an attack of gonorrhea have always appeared to me to be amongst the most clumsy and unpalatable possessed by our limited Pharma-copeia. Copaiba, cubebs and sandal-wood oil practically exhaust the remedies at our disposal, and every practitioner is fully aware of the trouble there is in the administration of these.

In my own practice I have a number of patients whose youthful indiscretions at times lead them astray, and the great difficulty with such people is to astray, and the great difficulty with such people is to give them medicine which they can take regularly without their employers' suspicions being aroused, for cases have not infrequently come to my knowledge where this has led to a notice of discharge being given. This may be a point which need not concern the practitioner, but it has many a time aroused my purely human sympathies.

I have for long kent an over eve in the book that

I have for long kept an open eye in the hope that some enterprising chemist would have solved the problem of rendering these remedies free from nauseous and irritating by-effects, but until some few months ago was quite unaware that any reliable, palatable and portable internal form of medication existed. There may, of course, be more than one on the pharmaceutical market, but I have only, more or less accidentally, stumbled across one, and my success with it has been so pronounced that I venture to

cess with it has been so pronounced that I venture to write about its effect, along with some other points, which will, perhaps, be of interest to busy practitioners who, like myself, cannot keep pace with scientific progress as they would like.

The substance to which I allude has the trade-name of Allosan, and is stated to be the allophanic acid ester of santalol; that is to say, it is a solid, organic preparation of the active principle of sandal-wood oil, with no taste whatever, and no irritating action on with no taste whatever, and no irritating action on the mouth, intestines, stomach, kidneys or bladder.

It is not one of those keratin-coated pills which are often so disappointing owing to want of solution. I hold no brief whatever for it, and merely wish to place on record some valuable experiences which I have had with it in the hope that others may be stimulated to test it. I have for a considerable time relegated copaiba to oblivion, because of its irritating, nauseating effects, and, until I discovered allosan, had distinctly felt its loss, having to rely upon various proprietary blends of cubebs and sandal oil. But since my discovery, if I may so term it, I have discarded these altogether. For some time I felt that I had a friend in urotropine, but one or two cases of hæmaturia, clearly due to it, compelled me to be very It is not one of those keratin-coated pills which are hæmaturia, clearly due to it, compelled me to be very discerning in its employment, where there was genitourinary mischief of at all an acute character.

I am a distinct advocate of the combined internal and external treatment of gonorrhœal conditions, and always employ them together from the beginning to the end of the case. I feel fairly confident that the internal medication not only assists the local cure, but also prevents general gonococcal infection, and particularly arthritic troubles. Salol was at one time one of my stock adjuvant remedies, but it cannot be pushed very far because of the gastro-intestinal derangement, and carboluria, not infrequently induced.

Sandal-wood oil is probably the best specific for internal use, but I have had quite a considerable number of cases of lumbar pain develop during its administra-tion, and practically every single patient treated by it complains of nausea and dyspepsia in a very short time. None of the untoward symptoms have appeared under the administration of the organic derivative mentioned. The sedative and anti-catarrhal actions of this compound are noteworthy, as is evidenced by the rapid relief of painful urination, the almost entire absence of distressing night erections, and the marked progressive lessening of urethral discharge.

Moderate purgation I hold to be almost a necessity,

especially in the acute stages of gonorrhæa, and gives wonderful relief in posterior urethritis. A favourite remedy of mine is mag. sulph. 3 dr., combined with pot. bromid. 20 to 30 gr., as a nightly potion.

The abortive treatment is a common-sense one and deserves more extended trial. It has not been practically successful in my hands, and one would like to know whether the failures are as eagerly recorded as

the successes in the medical journals.

For gleet I think nothing can improve upon silver nitrate ointment (3 or 4 gr. to the ounce) passed on a sound, and retained for three or four minutes at first, the time of retention being gradually increased. Coupled with gentle massage over the sound (a method I have seen recommended some years ago in the medical press), I think it has two great advantages. It ensures a pretty thorough application of the remedy to all the crevices of the dilated urethra, and enables it to reach the posterior urethra, whilst the use of the sound must naturally check the contraction of an incipient stricture, and may possibly cure it altogether—a thing one cannot hope from the use of soft

In the female I find the treatment advocated by Routh sound, practical and most effective. After a preliminary douche the vagina should be thoroughly swabbed up to and including the cervical canal, using a Fergusson speculum. The antiseptic should be a Fergusson speculum. The antiseptic should be fairly concentrated, and I usually employ mercuric chloride, or biniodide, or lysol. After the vagina has been swabbed the external genitalia must be thoroughly cleansed with a similar solution. The treatment of the urethra on these lines is rather pain-

ful, and one has usually to rely upon bougies. Naturally, one cannot employ this method until the acute stage has passed off, but it should never be undirected of the deleved of the deleved. duly delayed, as its primary object, of course, is to prevent the onset of specific salpingitis. In a few instances the antiseptics mentioned have not brought about success, but in all a 5 to 10 per cent. solution of silver nitrate or protargol have promptly cured after two or three applications at most. An excellent two or three applications at most. An excellent vaginal suppository for use in patients who object to the above treatment is one composed of plumbines. acetat. 5 gr., and opium 11 gr., in the acute stages, followed by a suppository of the following later on: Acid. carbol. I gr. and iodoform 3 gr.; if there be a tendency to chronicity in the discharge, add alum 10 gr. to the latter.

In regard to silver preparations, one may say that they are all open to the objection that they stain linen rather badly. The inorganic salt (nitrate) is always also open to the serious drawback that by contact with the tissues, etc., insoluble chlorides or albuminates are readily formed, and an impermeable coating produced, which naturally interferes with the penetration of the reagent.

New silver compounds are being produced in such numbers that their manufacturers must be throwing a severe strain on the Mexican mines. Most of these a severe strain on the Mexican mines. Most of these are, naturally, very expensive, and unsuited for general practice. Protargol, however, may be used in quite dilute solutions—even down to \$\frac{1}{2}\$ per cent., so that its use in practice becomes comparatively inexpensive. Many of these compounds are unstable, particularly the combinations with the organic acids, whilst I do not know of one which will keep for more than a few days in solution.

days in solution.

Of all the silver preparations on the market at or an the silver preparations on the market at present I have had no better results than with protargol. I think I may say that I have tried all the others at present known with exemplary patience, but without sufficient success, to justify me in adopting them in preference to the old-text-book remedies. Some practitioners have complained to me about the difficulty of making a solution of protargol, but I am bound to say I have never experienced any trouble at

My plan is simply to dust the substance so as to form a layer on cold water contained in a beaker or a large measuring glass, cover it over and leave it for a time. Agitation only renders the process longer and ultimate solution more imperfect. Transfer the solution to a dark glass bottle and the thing is done.

I have never, before the use of protargol, been favoured with such certain, rapid and permanent results as since I employed it. In a solution of from to I per cent. (I generally use the stronger solution) injected into a urethra previously washed out with boiled and cooled water, it will effect a cure more quickly than any other substance I know. It is, without doubt, not an easy matter for a patient, at any rate at first, to retain the injection for the half hour which is recommended, but after a while this becomes quite an easy matter. For chronic urethritis the full strength of the injection should be much greater, and it may be increased pretty rapidly up to 10 per cent. Coupled with the internal administration of allosan, one has, in my experience at least, an ideal programme of treatment for this all too common con-

As a test whether cure has been obtained in doubtful cases, I rely upon the simple method of providing my patient with a couple of glass slides which have been washed in carbolic and absolute alcohol, and wrapped in carbolised butter paper. He is instructed to express the urethra as completely as possible first thing in the morning on to one slide, cover it over with the other slide, rewrap in the paper and bring to me for microscopic examination. In cases of chronic urethritis, if gonococci are still present, there can be no question about the line of treatment—it must revert to the same procedure as if the inflammation were still acute, i.e., it must aim at the destruction of the causal cocci.

A few cases illustrative of the results of treatment

may be of interest:—

CASE I.—Male, 32, shop assistant, and compelled

to stand during most of the day at work. Painful urination and discharge four days after intercourse. Came to me late at night, and I merely put him on alkaline drugs and told him to come for more active. treatment next evening. On this occasion I gave him an injection of hydrogen peroxide (1 in 100) and showed him how to perform the injection himself. I also put him on allosan 15 gr., thrice daily, and gave him the usual cautions about diet. This treatment was persevered with for 14 days, at the end of which time not a sign or symptom of the disease remained.

Case 2.—Male, 24, clerk, and I suspect of dissi-pated habits; addicted to bouts of beer drinking. Disease developed five days after coitus. This patient came to me at once and confessed to having had two attacks before. I treated him on the same lines as the last case, but after a week he still complained of pain on micturition, which he said was getting worse. pain on micturition, which he said was getting worse. I discovered that he had recently been feeling so much better that he had "fallen from grace" and taken several glasses of beer. The urine was of high specific gravity and markedly acid. I put him on pot. citrat. 15 gr. t.d.s., for a couple of days, stopping the allosan during that time, but continuing the injections. At the and of the third week he was entirely cured and the end of the third week he was entirely cured, and was so astonished that he asked me for the prescrip-tion of the lotion and medicine, so that if ever he should need them again he would have them by him.

Case 3.—A rather severe case in an unmarried man, æt. 42. The discharge appeared three days after man, ex. 42. The discharge appeared three days after coitus, and was of a creamy consistency and full of gonococci. He was put on allosan with weak protargol injections, and told to drink freely of water and other innocuous liquids. There was a complete cessation of the gonorrheal discharge at the end of the ninth day of treatment, and next day there was nothing but proceed a little chorded denothing but prostatic mucus. A little chordee developed about this time, but was cured by inunction of the glans and prepuce with ung. sedativum. I thought him quite cured, but four days later he returned to me complaining of severe pain in the left testicle. On examination, the epididymis was found to be swollen and extremely sensitive. For this he was advised to use hot carbolic fomentations, I in 60, and the protargol injections and allosan were commenced afresh. At the end of three days more there was complete cure.

CASE 4.—Female, 25. Fille de joie. Date of onset somewhat uncertain—probably quite a fortnight ago. Profuse discharge and cystitis. Had been treating herself with lysol injections and capsules of copaiba for eight or nine days. Declined to submit to vaginal swabbing, so put her on allosan 12 gr., thrice daily, and gave the suppositories previously alluded to in this article. After three days' treatment the discharge had lessened considerally, and there was much less tenderness over the bladder. The treatment was persevered with, and at the end of another five days there was practically no sign of cretitie but the varied discharge that the property discharge the statement was persevered with and at the end of another five days there was practically no sign of cystitis, but the vaginal discharge still continued. The patient then consented to the vaginal swabbing, previously mentioned, protargol 5 per cent. being used. Next day the condition was infinitely improved, and after a second swabbing with 71 per cent. protargol, completely cured. Allosan was continued for three or four days longer, but this was probably unnecessary.

Though I have in one of the cases mentioned (No. 3) referred to a simple remedy for gonorrheal epididymitis, this is by no means the remedy I am attached to, which is naftalan. This is a substance which I have found of really priceless value in eczema in almost all its protean forms, but which I have only had occasion to use in some half-dozen cases of epididymitis, when I have employed it particularly in the acute stages. My practice has been to spread this substance fairly thickly on lint or linen and cover the entire scrotum with this; the usual suspender is, of course, always worn, and it is advisable to line this with cotton wool. A sitz bath, or the best substitute for it that can be improvised, is advisable night and morning, and if a couple of days' rest in bed can be secured so much the better. By means of naftalan, I have considerably shortened the duration of this painful illness, lessened the suffering, and had no relapses

whatever. None of my patients treated in this way required any opiate to tempt sleep. I am distinctly impressed with its value for this condition, and I propose to extend a trial of it to painful arthritic affections, and particularly those accompanying gonorrhœa, as it appears to have not merely an astringent and soothing effect, but to be absorbed, and thereafter exercised an antiseptic effect also. This last opinion is based on the remarkable curative effects it has on parasitic skin diseases.

# TIODINE IN THE TREATMENT OF DISSEMINATED SCLEROSIS.

By WILLIAM MURRELL, M.D., F.R.C.P.,
Physician to the Westminster Hospital, and Lecturer on Medicine and
Clinical Medicine.

Thiosinamin, or allyl-sulpho-carbamide, is prepared by warming oil of mustard with alcoholic solution of ammonia.

Fibrolysin is said to be a salicylate of thioscya-

min.

Tiodine is thiosinamin-ethyl-iodide.

All these substances have been used for the absorption of fibrous tissue, and have been employed in Dupuytren's contraction, for the removal of scar-tissue, in pyloric obstruction following gastric ulcer, and in various diseases of the ear and eye.

For some time past I have used tiodine in various chronic scleroses of the cord. It is slow in its action, and it is hopeless to obtain any very striking results unless the patient is willing to submit to a course of treatment of from four to six months' duration; and an even longer period may be required. This in a general hospital presents some difficulty, especially when the average stay of each patient is only twenty-six days and the bed costs nearly £2 a week. Moreover, patients are anxious to resume work as soon as possible, and take their discharge when there is a definite improvement in their condition. They cannot be treated as outpatients, for care has to be employed in the administration of the injections, and people in employment cannot attend once, much less twice, a day. I have many incomplete cases, but they are useless for publication.

Tiodine can be obtained in glass phials, each containing 0.20 centigrammes in 1 cc. I never give it by mouth, but always hypodermically, and with

strict antiseptic precautions.

On January 29th, 1908, I published in The Medical Press and Circular the case of a man, aet. 30, suffering from that form of lateral sclerosis known as "Erb No. II.," who was treated with tiodine. He was under observation, with intermissions, from April 8th to October 25th. He had twenty-six injections—an insufficient number, but the result was satisfactory. The first injection was followed by a well-marked reaction, with high temperature, which lasted for five days and terminated by lysis. It may have been an acute lobar pneumonia, but there were none of the ordinary signs or symptoms of that disease. I have since used it in a considerable number of cases of various kinds, but in none of them has a similar condition been observed.

The case I now record is one of disseminated sclerosis, and the patient has been in hospital for five months, during which time she has had 168 injections. The improvement has been exceptionally favourable, and I think it better to publish it rather than to wait for the chance of obtaining a series of cases involving probably a long delay.

R. M., æt. 22, a heavily-built, stolid-looking woman of Russian parentage and Jewish origin,

was admitted on November 3rd, 1908, suffering from disseminated sclerosis. She stated that from the age of thirteen she had been more or less shaky, but during the last six months had been so much worse that she was unable to follow her occupation as a servant. There was no family history of nervous disease and none of tubercle or cancer. Her previous illnesses comprised scarlet fever and whooping-cough, but there was no indication of syphilis, either congenital or acquired.

On admission tremor was very marked, but confined to the muscles in actual use. She was unable to thread a needle or to sew and experienced much difficulty in feeding herself. Her gait was spastic, the legs being stiff and moving only from the hips, whilst the knees were slightly flexed. She could not walk without assistance and could not stand alone. The tendon reflexes were all greatly exaggerated. Nystagmus was a prominent feature, being most pronounced on lateral deviation, but also present on looking upwards and downwards. The speech was staccato, halting and scanning in character. These were all the symptoms, except that the patient complained of pains in the limbs.

On November 7th she was put on tiodine, which was administered once daily until February 9th, after which the injections were given twice a day with occasional omissions. Up to March 11th, when the treatment was temporarily discontinued, the patient had had 134 injections, most of them in the buttock or abdominal wall, but a few in the arms. There was no reaction, the highest temperature recorded during her stay in the hospital being 101°, and that only once. Each injection produced a hard subcutaneous nodule somewhat smaller than a pea, but they did not suppurate. On March 4th, two fluctuating swellings appeared on the site of the two most recent injections, one the size of a walnut on the thigh and one on the arm as large as a hen's egg. There was no elevation of temperature and no local redness or inflammation, although there was a sense of tension with pain. The tumours consisted of blood-stained fluid with red blood corpuscles and leucocytes, mostly polymorphs.

The progress of the patient was one of uninterrupted recovery almost from the first. On February 25th she could stand unaided, walk steadily, and carry cups of tea to the other patients. She no longer complained of pains in the limbs. On March 2nd there was no tremor in the left arm and that in the right arm was very slight. She could thread a needle and sew perfectly well. The nystagmus had so much improved that she could read without inconvenience. The staccato character of the speech had completely disappeared. On March 26th, as a matter of precaution, the injections were resumed, but there was no further local trouble. She was discharged on April 3rd, and although she still occasionally comes to the hospital, there has been no return of any of the

symptoms.

## DILATATION OF STOMACH. (a) BY HARRY CAMPBELL, M.D., F.R.C.P.

The essential condition here is atony of the stomach walls, the muscular fibres of which tend to be flaccid and fail to contract properly upon the swallowed food; in other words, the "gripping" power of the stomach is at fault, the consequence being that food is unduly retained in its interior, and, just as in the case of the bladder with enlarged prostate, there is "residual" urine, so in the case of the stomach there is "residual" food, which tends

(c) Abstract of a Lecture.

to putrefy and cause irritation of its walls, and thus further aggravate the condition.

If there be definite obstruction, such as that arising from the cicatricial contraction of a pyloric ulcer, or the presence of a "ring" carcinoma, the

indication is gastro-enterostomy.

If there be no definite obstruction, the causes are such things as set up a catarrh, in the forefront of which I would place alcohol taken on an empty stomach, and, to a less extent, the taking of large quantities of tea and coffee. The condition is also sometimes found amongst those who habitually over-distend their stomachs by the ingestion of too large quantities of food—in plain words, gorging.

In the treatment of these non-obstructive cases the indications are:—Not to impose too much work on the stomach for a given time—i.e., the meals to be small in quantity and to be taken at more frequent intervals. The meal to be "dry," and meat should be the staple article of diet. Another indication of importance is the avoidance of carbo-

hydrates.

If the case be a severe one, the stomach to be washed out just before retiring to sleep-five clear hours after the last meal. This will remove any "residual" food and allow the stomach plenty of time for rest.

A tumberful of hot water to be sipped the first thing in the morning, so as to flush the stomach of any adherent mucus which may have collected

In aggravated cases, gentle massage applied one hour after a meal is often beneficial, as by such means the stomach walls are stimulated to contract.

N.B.—The condition is not to be mistaken for "achlorhydria," from which it can readily be differentiated by the results of a "test meal."

#### **OUT-PATIENT'S ROOM.**

METROPOLITAN HOSPITAL. Incontinence of Urine.

By LEONARD WILLIAMS, M.D., M.R.C.P.,

Assistant Physician to the Hospital, Physician to the French Hospital.

This patient, who is æt. 69, has been attending here for five weeks. He is an ancient master mariner who, you will observe, is smart and dapper in appearance and certainly does not look his age. He came to us complaining of diurnal incontinence of urine of ten years' duration. The accidents used to occur infrequently at first, but they have gradually increased in frequency, and when he first presented himself to us he used to wet himself as often as four times a day. He gives a history of two or three attacks of gon-orrhœa, but, as far as he is aware, he had never had syphilis. The nature of the sphincter trouble is not such as to suggest organic disease; that is, there is no difficulty in starting the act of voluntary micturition, and his enuresis is diurnal only; it is never nocturnal. On examination his urine was found to be perfectly normal. The bladder was not full, and digital exploration per rectum, which was very carefully performed by Mr. Sydney Vosper, failed to reveal the presence of an enlarged prostate or any other local cause for his trouble. A general physical examination of chest, abdomen and nervous system elicited nothing of any importance, and certainly nothing which seemed to throw any light whatever upon the origin of the incontinence. Functional troubles of this kind are not altogether unusual in men past 65 years of age. They are, however, commonly attributable to enlargement of the prostate and often entail what is called a "catheter life" upon their unfortunate subjects. I have advocated the treatment of slight degrees of this condition (a) by drop doses of the tincture of cantharides, three times daily, a method on which I have learned to place considerable reliance, and had it not been that our minds, that is, Mr. Sydney Vosper's and my own, were full of another method, I should have treated this patient by means of this drug with very considerable confidence. Our experiences had, however, engendered in our minds so much enthusiasm for the effects of thyroid extract in the management of nocturnal enuresis in children, that we determined to see what effect it would produce in the case of this elderly gentleman. The story of our experiences with this drug, how and why we thought of it, and the miracles which it wrought for us, are told in the Lancet of Saturday, May 1st, 1909, and need not be repeated now. Suffice it to say that out of 26 cases of persistent enuresis in children, treated by thyroid extract, we have had but one failure, and that some of the cases are so dramatic in their success as to be almost incredible. I had the pleasure of showing a good many of them at the Polyclinic on the 27th April.

But to return to our present patient. He presented himself on March 17th, and, moved by our above-mentioned results, we determined to treat him with 5 grains of thyroid extract, three times daily. On March 23rd the patient reported himself much improved. The incontinence was decidedly less. On March 30th he reported that, whereas formerly, his infirmity overcame him three or four times a day, during the past week he had been troubled on three occasions only. On April 6th there had been no incontinence. On the 13th no incontinence.

The moral is therefore obvious. Thyroid extract not only controls the vast majority of cases of nocturnal enuresis in children, but it also effectually counteracts the functional incontinence which is liable to occur at the other extreme of life, bringing grey hairs with physical and mental suffering, to an unregretted end.

#### **OPERATING THEATRES.**

GREAT NORTHERN HOSPITAL.

STRANGULATED RICHTER'S HERNIA.-MR. PEYTON BEALE operated on a man, æt. about 40, who had been admitted with the following history: On the evening of the fifth day before admission he had been eating mackerel. On the same night he was seized with violent colicky pains in the abdomen, which persisted to the time of admission. There had also been vomiting fairly persistent, and for the last two days this had been definitely fæcal. Temperature had not been raised, and the pulse had been and was abnormally slow. The abdomen was perfectly soft, quite easily palpated, not tender, and not in the least distended. The patient looked very ill. His published. distended. The patient looked very ill. His pupils did not contract to light, but he expressed himself as feeling well except for the occurrence of occasional colicky pains, vomiting, and inability to take food. Having been prepared, the abdomen was opened in the middle line below the umbilicus. On drawing aside a very distended coil of small intestine, a knuckle of bowel was seen projecting into a circular aperture about half-an-inch in diameter. The aperture was seen to be in the parietal peritoneum, and, on feeling it, it became evident that it was the internal abdominal ring. The parietal peritoneum and fascia transversalis were both very lax, so much so that the imprisoned knuckle of intestine, when gently pulled, could be brought outside the abdominal wound, thereby drawing forward the fascia transversalis with the internal ring and the parietal peritoneum covering With a little gentle manipulation the knuckle of imprisoned small intestine was easily pulled out of the ring, when it became clear that about three-quarters only of the lumen of the gut had been strangulated. After reduction it soon resumed its normal colour, and peristalsis became evident, the contents of the distended portion of intestine gradually making their way into the portion beyond the strangu-

lation. The sac of the hernia was merely a little peritoneal pouch pushed into the internal ring. As the strangulated portion of intestine was reduced, care was taken that none of the fluid (only one or two drops) within the sac was allowed to escape into the peritoneal cavity. The abdomen was quickly and thoroughly irrigated with hot salt solution, and the wound closed with the exception of a small aperture

in which a gauze drain was placed.

Mr. Beale remarked that the first point of interest was the fact that, although both groins and the whole of the abdomen were carefully examined, no trace of a hernia could be found. He drew attention to a case of femoral hernia which was reported in "Operating Theatres" of February 3rd, 1900, in which there was no trace of any hernia, although the whole of the abdomen and all the hernia apertures had been very carefully examined. The second point of interest was the fact that fæcal vomiting had been present for at least two days, and the intestinal obstruction had not been complete, nor was there the slightest abdominal distension. He said this was not infrequently the case in a Richter's hernia, and it proved that sufficient inverted peristalsis of the small intestine to produce by the firm constriction of only a portion of the lumen of the small intestine. The third point was the man's aspect and his dilated pupils, showing that he was suffering from a very acute septic intoxication. In cases where there was complete or partial obstruction to the onward flow of the contents of the small intestine, toxines, probably a bacillus coli, and other poisonous substances were absorbed by the blood and lymph. This produced the dilatation of the pupil, and appeared also to affect the brain so as to produce a diminution of the sense of pain. This was, of course, very commonly seen in the last stage of general septic peritonitis, where the pupils were commonly found widely dilated, and the patient quite free from pain and tenderness on palpating the abdomen. The fourth point of interest was the exceedingly lax condition of the fascia transversalis and parietal peritoneum; he did not remember having previously seen any case exhibiting this before. Here it was quite clear after reduction of the hernia that the internal ring with the parietal peritoneum covering it could be easily brought up from the iliac region to the incision in the middle of the abdominal wall. It was not unasual to see a very lax parietal peritoneum, but he had not seen a loose and lax fascia transversalis.

Malignant Tumour of Descending Colon.—The

same surgeon operated on a woman, æt. about 30, who had been admitted with an abdominal tumour in the left side. The tumour was ovoid in shape, about seven inches long and five in diameter, freely movable, quite painless. The patient did not know of its presence until she attended the out-patient department. history was as follows: -For the last five months she had complained of irregularity of menstruation and pain in the left side of the abdomen at the periods; she had never complained of any trouble as regards her bowels, and she had never passed any blood. Such was the absence of symptoms that it was quite doubtful whether the tumour should be investigated or not. In the out-patient department it was thought to be a renal tumour, and indeed it appeared exceedingly like a large hydronephrosis of the left kidney; the patient had no symptoms of urinary trouble, and an X-ray photograph of the tumour showed nothing; so that it was really upon the likelihood of its being a renal tumour that operation was performed. It may be stated that rectal and vaginal examination revealed nothing, and the only other likely diagnosis seemed to be an ovarian dermoid. Upon opening the abdomen it was at once evident that the tumour was a large malignant mass, involving the splenic flexure and descending colon, and clearly starting from the mesenteric attachment. After ligaturing the mesentery and adhesions in about 30 places, the colon was clamped about two inches above, and the same distance below the tumour; the whole was then brought outside the abdomen and excised; the two ends of the colon were stitched to the upper and lower ends of the wound respectively, and the clamps left on until it should be seen which was the upper and which the lower end of

the colon. It was hoped that this would be evident in two or three days, when the clamps would be removed, and in about a fortnight's time the ends of the colon would be sutured together. After removal the tumour was opened up, and appeared like a very hard colloid carcinoma. The whole of the mucous memcolloid carcinoma. The whole of the mucous membrane of the bowel within the tumour had disappeared, and from its appearance it seemed very remarkable that the patient should not have had any symptoms of obstruction or hæmorrhage from the bowels.

#### TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

MEETING HELD FRIDAY, APRIL 23RD, 1909.

Mr. R. CLEMENT LUCAS, F.R.C.S., in the Chair.

MR. HUGH LETT showed (1) cystic hygromata, in a girl, aged 15 months, under the right arm, on the right elbow, and over the right scapula. The mass in the axilla was soft, with irregular nodular areas. The skin attached to it was attached and dimpled. There were no dilated veins or pulsation. (2) Multiple masses under the skin of the thigh. The patient was a girl, aged 6 months. The swellings had been noticed since birth. On seeing the case three weeks ago the appearances had suggested lipomata, but one of the masses had now become softened and discoloured, and showed ulceration. The condition was, therefore, one snowed ulceration. The condition was, therefore, one of multiple tuberculous abscesses (3) A tumour of the femur in a boy, æt. 15. He had noticed a lump in the right thigh four years ago, which had been growing slowly since. It causes the patient a little pain when the weather is damp. The urine contains a trace of albumin. (4) A case of multiple osteomata in a boy, æt. 4½. He appeared to be normal until the age of 18 months, when his mother noticed lumps on his Osteomata can be seen or felt at the ends of both tibiæ and humeri, at the adductor tubercles of the femora, on the vertebral borders and spines of the scapulæ, at the outer end of the right clavicle, on the ribs at the junctions of the cartilages and bone, and symmetrical nodes on the skull. The boy was well, except that he got tired very quickly. The tumours were roughly symmetrical.

The CHAIRMAN said he had but little doubt that the three small swellings in Case 2 were tuberculous skin The fact that one had become discoloured abscesses. The fact that one had become discoloured since Mr. Lett saw it three weeks ago indicated the probable contents of the others-namely, sweet white pus. With regard to the tumour on the thigh, he thought that it was an ossifying enchondroma, usually known as an exostosis. The photograph showed that the bony part was growing, and as it was single he

would be inclined to remove it.

Mr. R. WARREN showed a specimen from a case of congenital stenosis of the rectum, colon, and part of the ileum. The baby was three days old, and had passed no motion since birth. The finger could be passed 1 to 2 inches into the rectum, and a small tube of 5 mm. bore would pass 3 inches or more. A little was performed, but the child died. Post-mortem, the gut was stenosed, but not blocked. Water could be passed both ways with a syringe.

Dr. PARKES WEBER showed a case of ductus

arteriosus without murmur. The child came under observation, aged 2 weeks, suffering from debility and cyanosis of variable degree. It could not take the breast properly. There was no murmur, and no certain signs of valvular disease could be detected. Its temperature was sub-normal, and it was subject to respiratory spasms, during which cyanosis was increased. There were 41 million red corpuscles to the cubic millimetre of blood. The child died at 6½ weeks. The foramen ovale was not completely closed, admitting the passage of a pencil 5 mm. in diameter. The ductus measured 15 mm. in length, and its channel was about 5 mm. in diameter, being a little wider at its aortic end; the aorta was very slightly constricted where joined by the ductus. The lungs showed atelectatic patches in the upper lobes. The liver was slightly enlarged.

Dr. CAUTLEY asked Dr. Weber whether he ascribed the cyanosis to the patent ductus or to the condition of the lungs. He thought himself that it was not due to patent ductus, because, if there were mixing of the bloods, there would be an excessive number of red cells, which was not the case.

Dr. WEBER thought that the atelectatic patches had a share in producing the clinical condition.

Dr. A. J. JEX-BLAKE showed a case of EXTREME DEFORMITY OF THE CHEST, WITH FIBROSIS OF THE LEFT LUNG.

The patient had always been weakly. There was a history of consumption on the father's side of the family. At the age of 7 the patient had bronchitis and pneumonia, and three months later was admitted to hospital with an abscess over the left lower rib which was found to communicate with the pleura. Two operations were done to let out pus. Three months later the whole left chest was flattened and dull, with tubular breath sounds. The fingers showed clubbing. There was a copious discharge from the tube and from a sinus close to the sternum. operations had been done subsequently. He had had a chronic discharge on and off from one or other of the sinuses in the chest ever since. The patient showed extreme deformity and collapse of the left chest, causing scoliosis and much limitation of the move-ments of the spine. The heart was displaced, the right lung emphysematous, and the fingers cyanosed and clubbed. Dr. Jex-Blake asked whether it was now too late to institute expansion of the lung, as there had been none for 41 years? Were breathing exercises or an operation such as decapsulation of the lung

or an operation such as accupational likely to do good?

Dr. E. I. Spriggs asked whether the child was bringing up sputum? If there was evidence of considerable dilatation of the tubes, he doubted whether respiratory exercises would be of much value. If not, he thought that, although they would not cure the deformity, they would prevent it becoming still more accentuated as the child grew older.

The CHAIRMAN thought that anything which might

bring about amelioration should be tried.

Mr. R. WARREN said he had seen a similar case, though less severe, improved by deep breathing, with chest had expanded one or two inches, and the scoliosis was improved. He thought it worth trying in the present case.

Dr. G. PERNET pointed out that there were some slight scars at the angle of the mouth, and a very little depression at the bridge of the nose. French writers considered that fibrosis of the lung was more liable to occur in patients who were syphilitic. He would like to hear the opinion of the physicians present on that point.

Dr. JEX-BLAKE replied that the child suffered from bronchitis on admission, but at the present time was not bringing up any sputum. There was no family history of syphilis. The mother had eight living children, a ninth had died in infancy, but there were no miscarriages.

Dr. G. CARPENTER showed a case of

CONGENITAL DILATATION OF THE COLON.

The child was a female, aged 1 month. Diarrhœa and vomiting began in the first week, and ceased on and voluming began in the first week, and ceased on March 28th. The bowels were then not opened until admitted to hospital on April 2nd. The abdomen was then enormously distended. Per rectum, thickening of the bowel could be felt, and offensive fluid fæces of fairly normal colour followed the withdrawal of the finger. Three days later, after treatment with enemas and aperients, normal motions were passed, and the distension had disappeared. It then began to increase again, but was relieved by turpentine and enemas. An X-ray photograph was shown, in which the colon, which had been injected with a solution of starch and bismuth, was obviously dilated, forming a U-shaped tube, with the base of the U at the splenic flexure, the ascending and transverse colon forming one leg of the U, and the remainder the other. He invited the surgeons to pass an opinion as to whether operation was advisable.

Dr. E. I. Spriggs thought that if the diagnosis was to rest on the skiagram shown, it was on an insecure basis, especially when it was remembered that a solution of starch and bismuth had been injected into the colon under a constant pressure, and that, unless the plate was pressed down on the colon, there would be a considerable spreading of shadow. The darkness on the right side of the U was also contributed to by the liver.

Dr. CAUFLEY supported Dr. Spriggs. He thought that a child with congenital dilatation of the colon ought to have a larger abdomen than the present child seemed to have. There might have been a temporary seemed to have. There might have been a temporary attack of dilatation from acute intestinal dyspepsia, which had now passed off. He did not understand why the case was spoken of as congenital, because even if there was dilatation, according to Dr. Carpenter the child was normally healthy until it got its attack of abdominal distension. And if a solution of hismath and storch was injected into a child's of bismuth and starch were injected into a child's colon, it would easily become dilated.

Mr. LOCKHART MUMMERY said the diagnosis could

be cleared up by the use of the sigmoidoscope.

Dr. CARPENTER replied that he still thought the colon was dilated, basing his diagnosis on rectal and bimanual examination, as well as on the X-ray picture. There was doubt about the thickening, and what else could it be due to? He would be glad to afford an opportunity for examination by the sigmoidoscope.

Br. CARPENTER showed a specimen from a case of "steeple skull" exhibited to the Section in December last. The child was at that time five weeks old, and died some little time after its exhibition. The specimen was the skull bisected in the median line.

The CHAIRMAN commented on the rarity of the condition, and said he believed there was no specimen of the kind in the College of Surgeons Museum.

Dr. CAUTLEY suggested that the specimen should be referred to an anatomist for report.

Dr. CARPENTER replied that he would not enter into a discussion of the skull before a full description had been written.
Mr. A. R. Thompson showed a case of

SOLUTION OF CONTINUITY OF THE RIGHT CLAVICLE since birth. The mother had fallen down some two weeks before the birth of the child. No deformity was noticed at birth. The boy showed a right clavicle which had apparently been fractured, the two portions being connected by a false joint, and forming an inverted V. Mr. Thompson thought the case was one of fracture, although such cases suggested the possi-

bility of cleido-cranial dysostosis

Mr. A. H. Tubby said this condition first came under his notice two or three months ago, in a child, aged 10 months. The labour had been a difficult one, the arms being behind the shoulders. On bringing the arms down, a distinct crack was heard, and there was found to be a deformity of the clavicle similar to that in Mr. Thompson's case. He operated and found an ununited fracture with a false joint, and wired the fragments together. He had seen a similar case, in which, despite wiring, no true union took place, and feared that in Mr. Thompson's case there would be no true union even if the false joint were excised.

Dr. Spriggs agreed that there was a fracture of the clavicle, and not cleido-cranial dysostosis. In most cases of congenital deformity of the clavicle of which he had seen photographs, there was evidence of defi-ciency of the membrane bones. In a case, for instance, published by the late Mr. Walsham, and in the photographs of Dr. Carpenter's cases, there was evidence either of an unclosed fontanelle, a globular cranium, a high-arched palate, irregular teeth, or some deformity of the lower part of the sternum. The present case showed none of these. Again, in cleidocranial dysostosis, although there was usually some irregular deformity of the clavicle on both sides, the fragments might be joined together by a loose joint, in which case the two parts fixed themselves in the same position as in this case. The case was an interesting one, historically, because a number of

cases of cleido-cranial dysostosis had been recorded as fractures even when the deformity was bilateral. Some anatomists, such as Paterson, of Liverpool, thought that the clavicle might be developed in two

The CHAIRMAN expressed his agreement with those who had spoken. He thought that operation should be undertaken.

Dr. E. I. SPRIGGS showed a case of MULTIPLE EXOSTOSES.

The boy came to St. George's Hospital in 1902, æt. 5, with a painful tumour in the upper end of the left tibia. At that time he showed several other small exostoses. Five years later, at the age of 10, he came to the Victoria Hospital, and then showed exostoses of the victoria riospital, and then showed exosioses of the vertebral border, of both scapulæ, and one on the spine of the right scapula, at the insertion of the pectoralis major, in the right humerus, at the lower end of both radii and ulnæ, on the left metatarsal, on the femora and tibia, and at the inner and outer ends of each clavicle. At that time he had a good deal of pain, and could not dress without assistance. Muscular power was fair. At present, two years later, the bony tumours were definitely less marked. The case was interesting as showing a few tumours at the age of 5, more at the age of 10, and a diminution in

their relative size since.

Dr. Milligan read a paper on a case of MENINGITIS ASSOCIATED WITH THE LEPTOTHRIX BACILLUS.

A child, aged 41 months, was admitted to hospital with a history of a fall on the head three days previously. There was general rigidity, conjugate devia-tion of the eyes to right or left, with lateral nystagmus. Craniotabes was present, and a bulging anterior fon-tanelle. Temperature, 101°, and pulse 104. A milky fluid was withdrawn by lumbar puncture, which contained an excess of polymorphonuclear leucocytes and a leptothrix bacillus, of which a photograph was shown. The organism was Gram-negative, and no growth was obtained either on agar-agar or blood The illness ran an acute course, the child serum. having a varying temperature, and dying on the fifth day after admission. A sub-dural meningitis was found post-mortem, extending over both hemispheres, especially over the vertex in front. There was an extravasation of blood on the side of the skull on which the child had fallen. The meninges were congested. Examination of the pus revealed the presence of diplococcus pneumoniæ. On opening the right ear, a small bead of pus welled up. A case of pyæmia and meningitis associated with a pathogenic leptothrix bacillus had been described by Ritchie and McDonald, who also spoke of terminal pneumococcal infection. Dr. McDonald had recorded five cases in which he found organisms similar to those described above in an epidemic of cerebro-spinal meningitis, and had concluded that the leptothrix was not a contamination. Dr. Milligan thought that the presence of leptothrix was more easily explained as a secondary infection, as this bacillus does occur about the mouth and throat.

Dr. CAUTLEY said that the important point was whether leptothrix was a cause of meningitis or a secondary infection. He had seen many cases of meningitis of that type, but without the leptothrix bacillus. The clinical course seemed to point to a pneumococcal infection.

Mr. N. BISHOP HARMAN read a paper on THE EFFECTS OF SCHOOL LIFE ON THE VISION OF THE CHILD.

After reviewing previous statistics, he communicated the results of the examination of 1,100 children, seen at the Belgrave Hospital and the Middlesex Hospital. In all cases the eyes were under the influence of atropine the ointment of 1 per cent. having been used four times a day for a week. Of every 100 children with defective vision, over 71 had hypermetropia, and less than 29 were myopic. These 100 children represent about 100 per cent. of the school children, and so the incidence of myopia amongst school children in London may be considered not to exceed 3 per cent. About 78 per cent. of the cases were girls. This Mr. Harman attributed to the girls having less outdoor exercise, and not being in such a healthy condition,

as well as to the fine needlework done in school by the girls. During the school age the incidence of hypermetropia increases, as may be expected from what we know of the growth of the crystalline lens. At the same time, the curve of myopia rises upwards to the highest positions on the chart, and such a phenomenon as this leads to the conclusion that the diminution of the hypermetropic astigmatism has been due to the transference of these cases to the myopic group. On the whole, the condition of the eyes of London children is very fair, especially if we compare them with similar returns collected in Germany. greater proportion of the cases of bad vision are due to natural conditions of the eye—that is, hypermetropia and hypermetropic astigmatism. New-born infants are always hypermetropic. The incidence of "manufactured" bad vision—myopia and its associated astigmatisms—forms between a quarter and a third of the whole of the cases. The evidence of the deterioration of astigmatic eyes indicates the desirability of a special oversight of these cases. Mr. Harman did not think that a healthy school life was harmful to the sight of the child population. In con-clusion, Mr. Harman criticised adversely the paper on the "Inheritance of Vision," by Amy Barrington and Earl Pearson. Several points in his experience led him to different conclusions. Miss Barrington and Prof. Pearson would lead us to suppose that the increase of myopia was due to fate, and hopeless, but in practice we find that the amelioration of school conditions and the relief of strain in ill-shaped eyes does stay the increase.

Mr. SYDNEY STEPHENSON congratulated Mr. Harman upon the clearness of his exposition. He agreed that it was futile to examine children's refractions unless the accommodation had been paralysed by atropine. Some years ago he examined 6,000 eyes, under the Poor-law, in children ranging from 18 months to 16 years of age. In these he found myopia present in 6.68 per cent. That was not very different from Mr. Harman's figures when the different range of ages was considered. He agreed that among the poor children of this country myopia was not of serious frequency. In his own figures the females were almost twice as much subject to myopia as were the males. He agreed in ascribing this to their employment in indoor work and lack of healthy exercise.

Mr. ERNEST CLARKE said that, although the subject was a tempting one, he would confine himself to reiterating what Mr. Stephenson had said as to the great importance of Mr. Harman insisting on the use of a cycloplegic. The statistics concerning the refraction of young people which were published without such were useless.

#### LIVERPOOL MEDICAL INSTITUTION.

THE LAST MEETING OF THE SESSION WAS HELD ON THURSDAY, APRIL 29TH

The President, Mr. T. H. BICKERTON, F.R.C.S., in the Chair.

#### SERUM TREATMENT OF TETANUS.

Dr. LLDYD ROBERTS reported a case of tetanus which had recovered under treatment with injections of carbolic acid and of anti-tetanic serum. The disease followed an injury to the hand from a circular saw. Symptoms appeared 10 days after the accident, and treatment was commenced on the 6th day of the disease. On the 4th and 5th day the symptoms had rapidly become more severe, and on the 6th day there was marked trismus, etc. The patient received 10 cc. of serum every 12 hours, and 15 minims of a 4 per cent. solution of carbolic acid every 3 hours for 1 day, and subsequently every 2 hours. On the second day of treatment the disease appeared to be arrested, and the patient was well 20 days later. Twenty-six injections of the companion of the second day of treatment was well 20 days later. tions of serum, and 236 injections of carbolic were given. The favourable result was attributed to the carbolic rather than to the serum.

Mr. Kelly referred to the prophylactic doses of

serum, and the value of intradural injections.

Dr. JOHN OWEN and Mr. DOUGLAS-CRAWFORD read a note on a case of

INTRASPINAL TUMOUR

which they had had under their care. It was localised at the 8th dorsal segment, and was successfully re-moved, the patient being shown at the meeting. They hoped to publish a full account of the case later.

Dr. W. B. WARRINGTON discussed the rarity of these cases, and urged the importance of physicians having sufficient faith in their diagnosis to urge an operation. Drs. Marsh and O. T. Williams read a paper on MENINGOCOCCIC MENINGITIS IN CHILDREN.

They referred to the importance of lumbar puncture in the diagnosis of tubercular meningitis from other types of the disease. In the last 14 cases of tubercular meningitis they had recovered the tubercle bacillus from the cerebro-spinal fluid. Four cases of tubercular meningitis with secondary meningococcic infec-tion were described in detail. The use of Flexner's serum had reduced the mortality from between 70 and 80 per cent. to 29.6 per cent. In children under two years the mortality was 42.4 per cent. in 59 cases, and in these the higher mortality was amongst those not treated until the seventh day of the disease. The serum was described, and its effect both on the organisms and the cytology of the fluid; being bactericidal and only slightly anti-toyic the serum must tericidal, and only slightly anti-toxic, the serum must be injected into the spinal canal. Fourteen cases of cerebro-spinal meningitis were considered. They varied in age from 3 months to 4 years, and 7 re-covered. Three cases treated in the first few days of illness all recovered. The amount of serum used in each case varied from 10 cc. up to 130 cc., and the number of injections from 1 to 5. In infants they advised small doses of 10 to 15 cc. Dr. Flexner confirmed this view. In older children they followed Dunn, of Poston, and gave 30 cc. on four successive days, the results upon symptoms and the fluid guiding their future procedure. They considered that this serum in carly cases promised extremely good results, and even in later cases it favoured the prognosis.

Dr. Owen referred to one case he had treated with

Flexner with satisfactory results.

Dr. Gullan referred to two. In one the fluid was not typical, nor was the diplococcus found. The patient recovered with Flexner. The second case, a girl of 18, had been ill a fortnight. After the first injection the patient passed into a state of coma, and, in spite of further lumbar punctures and injections, died.

Dr. John Hay referred to the occasional difficulty of differentiating in certain cases between acidosis and meningitis, and related a case illustrating the point.

OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY. NORTH OF

MEETING HELD AT MANCHESTER, APRIL 23RD, 1909.

The President, Dr. J. W. MARTIN (Sheffield) in the Chair.

A VOTE of condolence to the family of the late Mr.

Simeon Snell, proposed by Dr. LLOYD ROBERTS, and seconded by Mr. R. FAVELL, was passed.
Dr. H. BRIGGS (Liverpool) showed two specimens of

hæmatometra removed by the abdominal route. In each case the retention of menstrual fluid was due to congenital atresia of the cervix. The patients were unmarried women, set. 32 and 35 respectively. Microscopical examination of the uterine wall showed a great excess of fibrous tissue, and an absence of the glands of the endometrium.

Dr. A. DONALD (Manchester) read notes of a case of "Bilateral Abscess of the Uterine Appendages" occurring during pregnancy. Three weeks after spontaneous premature delivery, each abscess was drained extraperitoneally through an anterior colpotomy incision.

A marked improvement in the patient's condition immediately followed, but, two weeks later, symptoms of acute peritonitis appeared. On opening the abdomen a ruptured pyosalpinx was found and removed. Since then the patient has made a steady recovery.

Dr. J. H. WILLETT (Liverpool) showed the specimen from a case of "Cæsarean Section and Abdominal Hysterectomy" for carcinoma of the cervix, complicating a 7½ months pregnancy. The patient was a cating a 7½ months pregnancy. The patient was a multipara, æt. 34. Irregular hæmorrhage commenced at the end of the first month; later the discharge became offensive. The vagina was divided between clamps, but no attempt was made to excise the pelvic connective tissue. No enlarged glands were found. The mother made a good recovery, but the infant died when about four weeks old.

Dr. W. BLAIR BELL (Liverpool) read the notes of a case of "Acute Puerperal Sepsis with Thrombosis of the Ovarian Veins," which were ligatured and excised without success. Death occurred 16 hours after the operation. The details of a very complete bacteriological study of the case were given. Dr. Bell was of opinion that when septic thrombosis of the ovarian veins is diagnosed, immediate ligation and excision

should be practised.

The President, and Drs. Briggs, Donald and Lea

argued that the operation in such cases is useless.
Dr. A. DONALD (Manchester) read a note on the use of gauze drainage in certain cases of puerperal sapræmia, in which retention of lochia occurs from sharp anteflexion of the uterus with sagging of the body. Toxemic symptoms due to decomposition generally arise on the eighth or ninth day, or soon Immediate improvement follows intra-uterine douching, but renewal of the retention and of the symptoms is apt to occur. This is best avoided by the use of a gauze drain.

TREATMENT OF OBESITY.

THE treatment of obesity consists chiefly in a régime which the patient finds as irksome as complicated. For this reason few have the courage to persevere until a practical result is obtained. Dr. Moritz recommends a more simple treatment, quite as effectual; he has shown that an exclusive milk diet, varying between one to two and a half quarts a day is quite sufficient for the end in view.

Patients submitted to this cure do not suffer, in spite of the small quantity of nourishment ingested, from the disagreeable sensation of hunger experienced in following the other methods. Neither are they troubled by thirst, for they may allay it by adding water to the milk or taking water alone; but, in either case, the total quantity of liquid must not exceed two quarts a day.

This milk \*fgime is particularly beneficial in cases of obesity complicated with cardiac or renal lesions. Under its influence the heart troubles are soon relieved. the arterial tension is lowered and the frequency of the pulse diminished.

LINBAR CICATRIX AND TINCTURE OF IODINE. Every surgeon knows that incisions which heal by first intention under an antiseptic dressing and completely sheltered from all sepsis, do not always give that linear cicatrix desired both by the patient and the surgeon.

Din removing the sutures from the wound after 8 or 10 days the edges, although carefully adjusted, are frequently found to be somewhat separated super-ficially; a small fissure is the result, it granulates, and is finally transformed into an irregular cicatrix.

If the sutures were left in situ, a linear cicatrix would also be obtained, but leaving the marks of the

On the other hand, by observing what takes place during the healing process of an ordinary cutaneous wound, it is frequently found that the wound which did not appear very satisfactory on account of slight signs of irritation presented, furnished in the end a very good cicatrix, almost as fine as the scratch of a needle. Consequently, to obtain an æsthetic cicatrix, it is well to provoke a slight irritation of the edges of the incisions.

For this, says M. Schwarz, there is no better means than tincture of iodine. He has had recourse to this treatment for several years, and with constant success. He paints the surface with the tincture after the third or fifth day, and repeats the operation during two or three successive days. Small incisions require only one coating of iodine.

Prof. Grossich uses tincture of iodine exclusively for disinfection of the skin in every case of operation, and finds it superior to all classical methods; it has

also the advantage of great simplicity.

On the eve of the operation the patient takes a bath and, without further toilette of the skin, the region is rubbed with a plug of cotton steeped in tincture of iodine of 12 or 15 per cent. When the operation is terminated, the application is repeated along the line of ligatures. In this way M. Grossich practised over 50 operations, including the radical cure of hernia, kelotomy, amputation of extremities, laparotomy, ovarian cysts, etc., and the results were so satisfactory that for him, tincture of iodine represents the best method for disinfecting the skin and constitutes an excellent resource in urgent operations.

TODEIN OR BI-IODIDE OF CODEINE.

Experiments made in the Paris hospitals have shown that iodein possesses indisputable properties in broncho-pulmonary and cardiac affections, acting as a sedative on the cough and as an expectorant. No drug, it would appear, possesses in an equal degree such a sedative action on the mucous membrane of the larynx and the bronchi. The effect is so rapid that the most violent fits of coughing frequently yield to one or two spoonsful of syrup of iodein.

In pulmonary emphysema iodein rapidly relieves dyspnœa in freeing the bronchi more or less clogged

with mucus.

Bi-iodide of codeine give equally favourable results It has also been successfully used in in asthma. acute or chronic bronchitis, cedema of the lungs, etc.

The drug establishes better ventilation of the lungs by increasing the amplitude of respiration and in regulating the respiratory rhythm. It is thus that a large volume of air penetrates into the alveoli of the lungs through the congested bronchi, diminished in calibre by inflammation of the mucous membrane and the accumulation of pathological secretions; hence, a greater facility of interchanges with disappearance of suffocation and dyspnga and the patient

experiences a sensation of agreeable relief.

Iodein may be prescribed for months without producing any evil effects, nor is it necessary to increase the doses; the same doses taken by the same patients

always produces the same results.

Hæmatemesis.

Gelatin, 4 dr. Boil six hours in 5 ozs, of water to ensure liquidity. Add syrup of lemon, 1 oz. A tablespoonful every two hours.

## GERMANY. Berlin, May 2nd, 1909.

RENAL NEURALGIA. A CASE of this is described in the Münch. Med. Wochsch. by Oberarzt Dr. Urban. A woman, set. 26, was admitted into hospital for gall-stone colic. Attacks of biliary colic were said to come on every three weeks; calculi were also said to have been seen in the stools. There was a permanent dull pressure pain in the right side of the body, especially about the loins. There were violent attacks of pain in the right hypochondrium, beginning above and radiating backwards. The internal organs were healthy; the urine also was free from any morbid contents; there were no signs of hysteria. An operation was performed four days later, but nothing was found. Then there were pains about the cæcum, with rise of temperature (39°). Six weeks later the appendix vermiformis was removed. Adhesions and a small quantity of pus were found. A fortnight later there were complaints

of pain in the lower part of the abdomen. Repeated Rontgen illumination showed that there were no cal-culi. A third operation was performed four weeks later—viz., decapsulisation of the right kidney. The next day the pain and feeling of pressure in the right side, that had tormented the patient for a year and a-half, had disappeared. She was then quite free from pain, and looked in blooming health. Her weight, which at the time of the operation had been 48 kg., rose to 85 kg. in the course of a few months. In the Med. Klinik, Dr. E. Schlesinger lays down the limit set the

the limits of the

INJECTION TREATMENT OF NEURALGIAS.

He says that acute sciatica in all cases, and chronic sciatica in most, are not a field for treatment by injection. Rest in bed, quinine in small repeated doses, and galvanisation frequently lead to the desired result. In case of coincidence of sciatica with the uric acid diathesis, a strictly vegetable diet must be carried out. Treatment by injection is by no means a universal form of treatment for all forms of neuralgia. If a judicious choice is made by the physician, however,

it will rarely fail to satisfy expectations.

THE TREATMENT OF PLACENTA PREVIA
is discussed by Dr. M. Henkel in the Arch. f. Gyn., 86, 3. A considerable part of the puerperal mortality rests on placenta prævia, usually the central kind. By the usual treatment 50 per cent. of the children born at the end of term are born alive. When the cervical canal is closed, a tampon or a rubber ball is generally introduced into the vagina. Before the tampon is introduced the parts are shaved and well disinfected. Tamponade with gauze is the best, which has been soaked in a 2 per cent. solution of alum. If the liquor amnii has escaped, tamponade is no longer of use. Turning and metreurysis are now called for; the latter may, however, cause fresh bleeding. If the bleeding has already been excessive, but little more is required to bring on such a condition of anæmia that life can be no longer maintained. With a one-finger os uteri the writer performs turning in the following manner: Guided by the finger, the toes of the fœtus manner: Guided by the inger, the toes of the fætus are grasped by a pair of forceps. Digital dilatation is only suitable for the experienced obstetrician. Dilatation by Bossi's method has many disadvantages.

THE TREATMENT OF ECLAMPSIA is the subject of a paper in the D. Med. Wochensch., by Dr. Reifferscheid. In his last 30 cases delivery was effected immediately. The mortality was a part

was effected immediately; the mortality was 20 per cent., and thus far greater than by the expectant method. If the 15 cases were taken in which delivery was effected after the first attack, the mortality was 13 per cent. If the 6 cases were taken in which the birth of the child was spontaneous, or in which the first attack came on after delivery, the mortality was 23 per cent. The child mortality was much more favourable by careful artificial delivery than by the waiting method—viz., 20 per cent., against 40 per cent. by the latter method. The writer's advice is to operate at once, without narcotics or any sweating treatment, as this can only result in thickening of the blood; but he would bleed, give oxygen, or, if the attacks first came on during child-bed, he would perform decapsulisation of the kidney.

# AUSTRIA. Vienna, May 2nd, 1909.

CHRONIC HEPATITIS.

FLECKSEDER exhibited four preparations at the Gesellschaft für Innere Medizin of chronic inflammation of the liver. In all of these he found the status infantilis present, and asked the question if this condition were always present at the inception of hepatic inflammation? The first example was alcoholic cirrhosis in the hypotrophic stage; the second cirrhotic tubercular atrophy; the third biliary cirrhosis, ætiology uncertain; and the fourth a diffuse form of intra-hepatic cholangitis, probably arising from the bacteria coli. In all the four there are marked signs of infantilism, or lymphatic hyperplasia, but in most of them these were combined. This infantile state was also marked in the external genitals as well as the internal by the hypoplasia of the gland, want

of hair, smallness of the head and thyroid gland, as a narrowing of the vessels which seemed to be associated with hypoplasia of other tissues. From these conditions he reasoned that the lymphatic glands and liver suffered in the same way by these changes in the liver, or vice versā. He therefore contended that there was a period of pseudo-hyperplasia preceding genuine hyperplasia which established a low resistance against the various noxa. This individual infantile disposition of the liver opened up a wide question for investigation, and might greatly assist clinical work if a clear conception of the relationship did exist.

Bauer said that one of these cases, the alcoholic cirrhosis, had been treated in his clinic, and thought it right to mention that one of the prominent symptoms in the history was alimentary galactosuria. This patient eliminated from 10.8 grammes to 40 grammes of galactos in the urine in 24 hours.

OSTEO-ARTHROPATHIE HYPERTROPHIANTE

PNEUMIQUE. Bondl presented an interesting case of bone and joint affections succeeding thoracic empyema. patient, a young man, æt. 26, was operated on in 1907 for empyema, when several of the ribs were resected. After the operation a fistula was formed, from which a constant discharge exuded. To check this secretion two thoraco plastic operations were performed, without success. The figural is still present in the left side and the secretion profuse. In the autumn of 1908 the patient commenced to feel pains in the hands, ankles, and other joints, and when examined found the distal ends of the long bones greatly thickened, forming knobs. With the Röntgen rays this increase was found to be an apposition of new bony substantia compacta of the long bones, well marked in the metacarpal and metatarsal bones.

GASTRIC ADHESION. Politzer presented a female, æt. 24, in whom the stomach and colon became united, and were afterwards relieved by operation. Shortly after the flexura hepatica coli became bound up with the pars pylorica of the stomach with stenosis of the pylorus. this condition a rhythmic, intermitting rise and fall of the hydrochloric acid took place in the stomach, with the appearance of sarcinæ. Schmidt remarked that severe pyloric stenosis was always associated with sarcinæ, and where the pyloric stenosis was moderate or slight, the presence of sarcinæ was intermittent, which seemed to run parallel with the congestion of the stomach.

#### FROM OUR SPECIAL CORRESPONDENTS AT HOME.

#### SCOTLAND.

EDINBURGH POST-GRADUATE COURSE.—The post-graduate course in medicine, which has proved so successful during the past three years, will again be given this autumn. It runs from August 30th to September 25th, and comprises (1) a daily special lecture on some subject of general interest; (2) a general course; (3) special courses on bacteriological and other practical work; (4) a surgical course. The syllabus has been issued, and may be obtained from the Secretary, Faculty of Medicine Office, University of Edinburgh. Early entry should be made for the surgical course, or any of the limited classes, as it has been found in past years that these sections of the course soon fill up. Women are entitled to attend the course. The University Union is open to members on payment of a small fee, and arrangements have been made permitting those attending the course to board in the University Halls of Residence.

GLASGOW ROYAL INFIRMARY.—Dr. J. H. Teacher has been appointed Pathologist to the Royal Infirmary, Glasgow, on the resignation of Dr. Galt. Dr. Teacher is the Lecturer on Pathological Histology at the University, and is assistant Pathologist at the Western Infirmary and Sick Children's Hospital. His important work on chorion-epithelioma is well known. There was an unusually keen competition for the position, in view of the pending change in the relationship of the Royal Infirmary to the University. There is it seems, considerable prospect of a new chair of

pathology being instituted in the Infirmary.

Edinburgh University.—Professor Chiene has received further leave of absence from the University, and during the summer Mr. Wallace will carry on the class of operative surgery, and Mr. Alexis Thomson the clinical work associated with the chair. Although Mr. Chiene is not yet able to resume his duties, his friends will be glad to learn that his health shows considerable improvement.

GRANTS TO SCOTTISH UNIVERSITIES .- The Treasury Committee appointed to consider the claims of the Scottish Universities to additional State assistance, visited Glasgow some weeks ago, and are expected to make a tour of inspection of the Edinburgh school this month. It is understood that the bulk of the committee's work in the way of hearing statements will be done in London. At present the Scottish Universities receive £40,000 from the Treasury, and the inadequacy of this grant has for long been a grievance.

DR. STUART McDonald, lecturer on Pathology in the New School of Medicine, Edinburgh, and Pathologist to the Children's Hospital has been appointed to the post of Pathologist to the Royal Infirmary, Newcastle-on-Tyne. Dr. McDonald is one of the most popular teachers in the Extramural school, and his departure from Edinburgh is greatly regretted. He has taken a leading part in all questions concerning the improvement of the medical curriculum, and is a most enthusiastic worker in pathology. His friends in Edinburgh feel that the Newcastle authorities have been fortunate in securing his services.

#### LETTERS TO THE EDITOR.

 $[\mbox{We do not hold ourselves responsible for the opinions expressed by our Correspondents.}]$ 

#### THE PROVIDENT DISPENSARY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,-Those who complain of the hard times to which the medical profession is subjected, but who are content to sit still with folded hands when reform is mooted, should think over problems such as those raised by Dr. George Crichton in your issue of April 28th. Whether we agree with that gentleman's views or not, we should all be grateful to him for bringing forward practical points for discussion in a clear and crisp manner. Personally, as a medical practitioner of many years' standing, I am no less opposed to the provident dispensary than to the free and unchecked free hospital system. Both constitute in my opinion gross forms of competition with a highly-skilled and underpaid profession. The fact that a few pence are paid by the patients in the provident dispensary may save their faces, but it none the less leaves the door open to abuse as great or greater than that which has grown to such an enormous extent in the hospitals. Indeed, when the latter exact fees from patients, as some of the largest and wealthiest hospitals do not hesitate to do, the difference between the voluntary hospitals and the provident dispensaries is much like tweedle-dum and tweedle-dee. If anything be charged at all by a so-called charity, it should in no case be less than the minimum fee charged privately by outside practitioners to persons in a corresponding class of society. I trust some of your readers will furnish Dr. Crichton with the necessary data for a further communication, in which he will analyse with his usual

logical precision the present situation.
As for myself, I think all charity should be pure charity, and that no payments by patients are under any conceivable circumstances justifiable. How does that view of the case commend itself to Dr. Crichton?

I hope, Sir, that you will encourage in the columns of your valuable journal questions that are of practical importance to the rank and file of the noble pro-fession to which we are proud to belong. But mere

nobility butters no parsnips, and it is a sad irony that saddles the efforts of philanthropy with cramped homes and starved professional means.

I am, Sir, yours truly,

G. P. OF MANY YEARS STANDING.

Birmingham.

GENERAL PRACTITIONERS AND MIDWIVES. To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,-In Dr. G. de G. Griffith's letter I fail to see a reply to mine. A minor point raised in my letter is briefly noted, and I am informed that information on the point can be obtained from agents. The vital points raised are unanswered. The letter is really a very spirited missionary appeal. Now I can fully appreciate Dr. Griffiths' lament over the lack of medical below in foreign lands but also I fail to see medical help in foreign lands, but, alas! I fail to see why the medical and surgical treatment of even the most heathenish of the heathen should be entrusted to quacks whom we should not tolerate for one moment in England. When we consider the enormous sums of money which are annually spent on Foreign Missions, one wonders if a considerable sum would not be well spent in sending out duly qualified men and women to attend to the bodily ailments of these unfortunate human beings. Two quotations seem to me rather apt when considering this question. Salus populi suprema lex, and Mens sana in corpore sano. We are so imbued with the idea of "saving souls" that we are apt to disregard the temple containing those souls (the body). I shall not trouble you with any further communication upon this subject, as I have achieved my chief the containing the soul of the containing the soul of the containing have achieved my object in pointing out the features in Dr. Griffiths' communications to which a general practitioner having the best interests of his profession at heart must object.

I am, Sir, yours truly,

S. J. Ross. Monkhams, Bedford, April 28th, 1909.

"POST-OPERATIVE TETANUS" OST-OPERATIVE TETANUS" AND POST-OPERATIVE SCARLATINA SYMPTOMS. To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In looking over your Journal for April 28th, 1909, I read the article on "Post-operative Tetanus," and it calls to mind the cases to which Sir James
Paget drew attention, of scarlet fever attacking his
patients after operation. When I read the report of patients after operation. When I read the report of those cases I drew Sir James Paget's attention to the fact that though apparently scarlet fever, they were really cases of septicæmia producing the redness and other symptoms so strongly resembling those of true scarlatina.

In was in 1875 that I read a paper at the Obstetrical Society showing that what was considered to be scarlet fever attacking the puerperal patient was not scarlet fever at all, but the result of sepsis other than scarlatina, and that no evidence of scarlatina having been brought to the woman could be traced, and that all the circumstances and conditions surrounding her precluded the probability and possibility of contagion from scarlatina.

I remember that before we could be admitted into the operating theatre when certain operations were being performed we had to sign a book, or make the statement, that we had not been in contact with or near any such contagion as scarlatina, which was looked upon as the worst foe, and was the dreaded enemy of the puerperal woman. In my paper I termed the symptoms "bastard scarlatina," inasmach as, though resembling scarlatina, they are another source of blood-poisoning altogether. arose from

The first patient whose symptoms called my attention to the origin of those cases of "bastard scarlatina" was a lady whom I attended in Blackheath. I could not see her every day, and in my absence a clot had formed in the uterus, and some absence a clot had formed in the uterus, and some decomposition had begun. When I got down the nurse told me she was afraid the lady had scarlatina. I examined, and feared so also. I then palpated the abdomen, and on turning up the bedclothes to do so noticed an unpleasant odour. Finding the uterus enlarged, I pressed on it, and expressed a large clot,

which was fœtid. Having done this, the vagina was well washed out, till the water returned quite free from smell.

The douching was repeated daily till it was longer necessary; and the scarlatina symptoms disappeared so quickly, that it caused me to ask myself the question, Was it scarlatina at all, or was it wholly produced by the decomposing clot? We made most particular inquiries re scarlatina, and came to the conclusion that that ailment was not the origo mali, but that all the symptoms were blood-poisoning from the decomposed clot, and observation of cases recorded in the intervening years have proved the correctness of the diagnosis.

At the Obstetric meeting to which I refer Dr. Priestley was in the chair, and Dr. Robert Barnes and Dr. Braxton-Hicks sat on the bench behind me.

I am, Sir, yours truly,
G. DE G. GRIFFITH.

London.

THE BIRTH-RATE QUESTION AND FRENCH DEPOPULATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—To those of your readers who may care to learn what is thought by responsible French statesmen of the position of their country in face of a diminishing population, brought about by the deliberate action of the whole people, I commend the perusal of an article in the Reveue Blew of April 24in from the pen of M. Paul Strauss, Member of the Senate. If the breeding of the race could be organised on exact scientific lines, based upon prudence, and guided by the teachings of established knowledge—an guided by the teachings of established knowledge—an aspiration at present purely Utopian—the causes for anxiety need not exist, and the French would not be faced by what M. Strauss describes as the "agonising problem" of the day—the question of the existence of their country as an independent Power. Every year that passes makes France inferior to Germany; she could not now defend herself in a "fight to a finish"; she has only 39,000,000 of people against 65,000,000 to draw upon. History repeats itself. A great, virile race, in contact with a dying people, has always in time conquered or devoured its weaker neighbour. Germany will need room for her million annual increase, and although she may not demand French territory, she will surely make France, sooner or later, yield up all her oversea possessions, which, from the population point of view, are entirely useless to her. Germany, when the time arrives—when her statesmen believe the moment has come for action can march in and seize and hold French soil until her demands are acceded to. There would be no Power or coalition of Powers capable of effectual interference, even if Austria was not, as she is, bound to Germany by hoops of steel—bound not only by gratitude, but by the imperative necessities of her own situation. Surely all this forms an object-lesson for ourselves. We are following the example of France. I have in previous letters explained how our course must prove more rapidly disastrous to ourselves than to our decadent neighbour, but there is as yet no sign of recognition of these facts by our people or their responsible leaders.

I am, Sir, yours truly,
A STUDENT OF SOCIOLOGY.

April 28th, 1909.

#### **OBITUARY.**

GEORGE ROE CARTER, M.R.C.P.I., L.R.C.S.I.

WE regret to record that Dr. George Roe Carter. Medical Officer of Health of the Penge District Council, died on April 26th at his residence at Anerley. where for the last 30 years he had an extensive practice. Dr. Carter spent the earlier years of his professional life at St. Lucia, West Indies, where he was Colonial Surgeon and Medical Officer of Health to the island. He was educated at Ledwich School. Dublin. At Meath Hospital he was awarded a prize

for his surgical work, and he afterwards became House for his surgical work, and ne alterwards became House Surgeon to the institution. He was also a Fellow of the Royal Institute of Public Health, and an exmember of the Councils of the British Gynæcological Society and the Irish Medical Graduates' Association. His qualifications, which were obtained in Dublin, in-cluded the membership of the Royal College of Physicians and the Licence of the Royal College of Surgeons. Dr. Carter was born in 1843.

# MILITARY & NAVAL MEDICAL

It is reported that motor car hospitals will be given exhaustive trials at the German autumn manœuvres to take place in Wurtemberg. If the results are satisfactory they will be introduced into the Army. These motor car hospitals are designed to move from position to position with the firing line with much greater tion to position with the firing line with much greater ease than the ordinary ambulances. They are to be equipped with medical and surgical appliances and capable of conveying wounded men—ten or twelve—quickly and comfortably to field hospitals from the field of action.

Some friction has arisen between the War Office and Mr. Sydney Holland, of the London Hospital, regarding the method of recruiting for the Territorial Nursing Reserve. Mr. Sydney Holland explains matters in a letter to the *Daily Telegraph*. Two very pregnant sentences appear in this letter, which are these:—(r) "Is it not curious that in every war so far the nursing arrangements of the War Office have broken down, and they have had to come to civilians to help them out?" (2) "And yet, here again, when in time of peace, arrangements are being made, the War Office go right against the opinions of those whom they have selected and those who have been appointed to advise them on nursing matters because of their special knowledge."

THE reduction of the military force in South Africa, and also the now almost complete immunity of the troops in Malta from the fever which was so prevalent at that Mediterranean station, and went by the name of "Malta fever," has been the means of bringing home several (some 20) full pay Medical Officers, who have to be provided with billets at home. This has necessitated dispensing with the services of a number of retired pay Army Surgeons who had held recruiting appointments in the London District, and elsewhere, for several years. The disappointment to the retired pay officers was very great, but the Director-General of the Army Medical Service, Sir Alfred Keogh, with his usual thoughtfulness and consideration, has offered some of these retired officers stations where civilian practitioners had been employed, e.g., Nottingham, Sunderland, etc. Employment for a retired pay Medical Officer means £150 per annum, added to his retired pay, which is by no means to be despised. So keen is the competition by retired officers for any billet carrying this extra emolument that it is well known at headquarters that there are 30 applicants for every vacancy. As a rule, it is more economical to employ retired pay medical officers at £150 a year in stations than civilian practitioners drawing fixed sums per head of recruits examined or soldiers receiving medical aid. As the War Office has ever an eye to economy, it explains why some retired Army Medical Officers have been offered stations which have been served by civilians up to the present.

THE Army and Navy Gazette states that it is not generally known that the Secretary of State for War was questioned by Mr. Lupton, M.P. for Sleaford, on the subject of enteric fever. Mr. Haldane's reply, which bears on a very important matter, viz., inoculation for this fever, stated that in the last year arrangements had been made for the voluntary inoculation against enteric fever of officers, warrant officers, N.C.O.'s and men of the Regular Army at all stations at home prior to their departure for foreign service. Arrangements, he said, had also been made for

voluntary inoculation against typhoid (enteric) fever being carried out on board all troopships, and in all commands, including India where enteric is preva-lent. Statistics on the subject are not yet available. No arrangements have been made for the voluntary inoculation of the Territorial Force in this country. These inoculations are performed by officers of the R.A.M.C. The anti-typhoid vaccine is prepared at the Royal Army Medical College.

A LETTER appears in the Naval and Military Record, of April 15 headed "Sisters in Royal Naval Hospitals." It is signed "One Who Has Escaped." The letter gives a somewhat pitiable account of the work and the new regulations. In respect of the latter, the correspondent says: "The new rules seem to have been carefully framed to make the lives of the sisters as miserable as possible, without any corresponding benefit to the patients; in fact, the sister is so rushed with other duties that she has hardly any time to give to their individual care." The letter ends with a warning to any nurse who has the smallest chance of a sister's billet in a civil hospital not to join the navy under its present conditions, or she will bitterly regret it.

For the present Infantry Reservists joining the Royal Army Medical Corps will only be accepted for training at the following centres, viz., Aldershot, Chatham, Colchester, Dublin, and the Curragh Camp.

THE Indian Medical Congress, which was opened at Bombay on February 22nd, has proved an immense success from every point of view, and we hope to furnish our readers with some of the papers read thereat. His Excellency the Governor presided at the inaugural ceremony, and presented Major Ronald Ross, Captain Jones, I.M.S., Captain Nicholls, I.M.S., and Professor Ghujar with the coveted medals. Surgeon-General A. T. Sloggett presided over Section I., Surgeon-General Hamilton Section II., Surgeon-General Benson, Section III., Lieut.-Colonel Crimmin, Lieut-Colonel Dyson, and Dr. Turner presided over Section IV. alternately, and Surgeon-General Stevenson over Section V.

#### REVIEWS OF BOOKS.

THE DIAGNOSIS OF BACTERIA. (a) This small work supplies a long-felt want. Of books on bacteriology there are many, but what the student and practitioner often require is a handy volume such as this, which gives in condensed form all the information which the average student is expected to know regarding bacteria and their mode of recognition. The various bacteria are placed in groups, and their special characteristics by which they may be severally recognised are carefully indicated. To the average student the various characters presented by the pathogenic bacteria always form a difficult study, but the subject is treated so tersely in the book under review that the task of the learner is greatly simplified. The different staining methods are clearly set forth, without any unnecessary detail, and even the staining of spores and of flagella is referred Then follows an account of Widal's reaction and the opsonic index, while the various reactions used in the diagnosis of tuberculosis are all referred to with sufficient fulness. The mode of obtaining pure cultures is very accurately explained. A very useful section is the one dealing with sterilisation as applied to bacteriological work. The mode of conducting post-mortem examinations on inoculated animals is also referred to at some length. The volume concludes with a reference to spirochæta pallida, trypanosomes, and the organism of malaria. The volume is one which we can recommend with

It forms not only an excellent every confidence.

<sup>(</sup>a) "Differential Diagnosis of Bacteria and Bacteriology." By E. P. Minett, M.D., D.P.H., M.R.C.S., L.R.C.P., F.C.S., Assistant Bacteriologist and Demonstrator in Bacteriology and Microscopical Pathology to Guy's Hospital. Crown 8vo., pp. viii., 72. London: Bailliere, Tindall and Cox. Price 2s. 6d. net.

laboratory companion, but it may be used as an introduction to the study of bacteriological research. Students preparing for examination will also find this book of the greatest possible service, as it supplies an immense amount of practical information in a handy and easily remembered form. The author's statements are characterised throughout by accuracy and clearness, and altogether this little work is a most commendable production.

SPECIAL HOSPITALS. (a)

This monograph opens with an interesting historical sketch, which shows how the hospital took its origin in the Temples of Ancient Religion. These temples "were something more than places of refuge for the sick, they were sanctuaries for worshippers, seats of learning for the student, health resorts for the convalescent, and centres of recreation for the whole people." "Here the priest-physician treated disease, taught philosophy and continuation to the same treath of taught philosophy, and gave instruction in the sacred science of medicine." To the Greek especially health and religion were inextricably interwoven. Many of the Hellenic shrines were known as Temples of Health; sanctuaries were consecrated to Æsculapius, the God of Medicine, and to his daughter Hygeia, the Goddess of Health; Apollo was the Healing God. (It may be interjected here that the latest scientists regard him in the same light.) Mr. Kershaw traces specialism in medicine back to the earliest recorded times. "It was nowhere more developed than in the ancient Universities of Egypt, of Greece and of Rome. In Egypt the sacerdotal doctors divided the human body into thirty-six anatomical parts, each part being dedicated to its own special deity." Hippocrates tells us that in Greece a large proportion of the Temples of Health, presided over by the Asclepiadæ, and erected as receptacles for the sick . . . were built in the vicinity of therms or medicinal springs: "which method of treatment clearly demonstrates the existence at that time of hydrotherapy as now practised at our modern spas." Moreover, the Greeks and Romans had their oculists, as is proved by the inscriptions on ancient marbles.

Mr. Kershaw follows the development of specialism

through early Christian times, through the Middle Ages, to its climax in the nineteenth century. This chapter, it should be said, is admirably illustrated by woodcuts of ancient and mediæval subjects. Subsequent chapters deal with the origin and development of modern special hospitals in the United Kingdom, their advantages on the score of economy, their enormous value to medical education, and their freedom from abuse, in the matter of charity. The book contains some interesting statistics, and concludes with a list of special hospitals founded in the United Kingdom during the nineteenth century, giving the names of the founders, the number (during the year 1907) of medical visitors, of post-graduate students, and of patients sent by medical practitioners.

Mr. Kershaw, who has occupied the post of Secretary to the Central London Throat and Ear Hospital for many years, pays a tribute to the modern nurse, and to the work done by medical women who still have to face opposition in their career.

TREATISE ON CHEMISTRY. (b)

TREATISE ON CHEMISTRY. (b)

This well-known work, which first appeared in 1878, was reprinted in the following year, and again with alterations in 1883, 1887, and 1893, a new and entirely revised edition was issued in 1897, and the present issue published in September, 1907, is again entirely revised. In a work of this nature, dealing with an enormous number of details, processes, etc., both manufacturing and analytical, both of which are subject to continual variation and improvement as manufacturing and series of the series of ject to continual variation and improvement as manufacturing and analytical knowledge progresses there is always a danger that old matter from previous editions may escape alteration. After a careful examination of

that the various monographs have been well brought up-to-date in nearly all cases. Probably the reason which has compelled the exclusion of some of the recent information which the revisers would have been glad to include was the practical necessity of keeping the size of the volume (which now extends to over 1,400 pages) within manageable limits. The work of revision has been so well carried out that it is an invidious task to criticise what are, after all, minor details. Among a few other omissions, however, we would point out that the assay of wolfram for tungstic acid is dealt with in a very short manner, and the working details that should accompany it are wanting. Under the article on tin it is stated that "it has been found in small quantities in Siberia, Guiana, and Bolivia, in a native state—though, according to Forbes, that from Bolivia possibly may have been an artificial product." The probable explanation of all reported discoveries of metallic tin is that if not due to ancient smelting operations, the reduced metal has been produced by an accidental smelting due to bush-fires. The detection and assay of tin cassiterite is not at

the present edition we find that is not the case, and

all adequately dealt with, and no mention is made of the necessity for separating the black oxide by "vanning" by the gangue with which it occurs, which is the first step in assaying any ore for tin. The smeltmethod of assay by cyanide and the smelter's assay using anthracite are not given. The electrolytic methods for the recovery of tin from tin scrap of old "tin" cans is not dealt with, though this industry is now assuming considerable importance.

Turning to other articles, for example, those on gold, silver, copper, uranium, etc., the details given on the methods of assay extraction, etc., are much fuller and more up to date. For reasons of space, it seems that in the next edition it will be advisable to deal with the vast quantity of matter involved in two volumes rather than one.

The above criticisms must not be understood depreciating the immense value of this volume, which is a practical necessity to every working analyst. If the publishers were able to reduce the cost of the book, there are many men who would be able to add to their shelves who are debarred by the present price, and the increased sales that would unquestionably result would make it possible for revising to be undertaken at more frequent intervals to the increased benefit of all concerned

It is only by means of frequent issues that a work of this nature can be properly kept abreast of the perpetual changes and improvements that are almost daily occurring in methods of manufacture and analytical processes.

#### LITERARY NOTES.

WE can say without hesitation that Dr. Langdon Brown's "Physiological Principles in Treatment" Book on treatment that we have read for a decade. Without seeking to be exhaustive, or to rival the comprehensive text-books on the subject, this little work so happily combines the best of modern physiological thought with the most practical branch of medicine as to make the reader wonder why all physicians are not compelled to study pure physiology—supposed by many to be as useful a subject as pure mathematics or transcendental philosophy—as a regular daily pursuit. Dr. Langdon Brown has the rare accomplishment of being a first-rate physiologist and physician at the same time, and his teaching, much of it quite new, is that rational treatment must be founded on sound physiology; if not, either the treatment or the physiology is wrong. He develops his thesis with extraordinary care and skill, and which, to our mind, reaches their highest point in the chapters on digestance. tion. We venture to say this book will be a revelation to most readers, and they will never again prescribe mist. gent. alb. without the comforting thought in their mind they know why they are doing it, and what it may reasonably be expected to accomplish.

<sup>(</sup>a) "Special Hospitals; Their Origin, Development and Relationship to Medical Education. Their Economic Aspects and Belative Freedom from Abuse." By Richard Kershaw. Pp. 72. London: Geo. Pulman and Sons. Ltd.

(b) "Treatise on Chemistry." Roscoe and Schorlemmer. Vol. II., "The Metals." Pp. 1436, with many diagrams. London: Macmillan and Co., Ltd. Price 30s.

An ingenious, almost startling book is Dr. Rumley Dawson's "Causation of Sex" (H. K. Lewis). The work of a general practitioner who has taken twentytwo years developing his theory, collecting materials, and checking his conclusions, the volume is a credit to the enthusiasm and energy of the author, if it be nothing more. If Dr. Rumley Dawson is right, and if his conclusions are finally accepted, his name will stand with those of Jenner or Mendel; if incorrect, he will remain one of the very few men who have to penetrate one of the most tantalising arcana of Nature. Briefly the theory is that the male element has no influence in the determination of sex, the sexual properties lying entirely in the ovum; and, further, that the male ova are derived from the right ovary, the female from the left. As each ovary produces an ovum each month in alternate months, it is possible to predict, and indeed for the parents to decide on, the sex of the child. How Dr. Dawson works his theory out and the evidence he brings to bear on it, we must leave readers to find out for themselves. This they should be eager to do, for they may be reading the book of the century. As to that we reserve our own opinion.

No one who has read Dr. William Murray's "Rough Notes on Remedies" will be surprised that Mr. H. K. Lewis has issued a sixth edition. Dr. Murray is one of the lessening number of consultants who has not lost faith in drugs quad drugs. In an age of scepticism he preaches the old gospel which has stood so many generations of practitioners in good stead. "I myself have an undying faith in drugs, from a dose of castor oil to the newest synthetic compound with twenty letters to its name; and remember it is not always the impotence of the drug which causes failure, but the want of proper administration; therefore study the best methods of combining and administering your drugs." These are bracing words, and many examples of how the principle they teach are given in this little book. It is a book that should be given to the young who are emerging from the post-mortem room and the bacteriological laboratory, and feel the impotence of the Pharmacopeia to do battle with the hosts of Nature. And to the older generation it will do much to strengthen the muscles of their faith.

THE "Medical Annual" has become almost as much of an institution as the "Medical Directory," and although it has not attained the portentous size of its homologue, the growth in bulk and importance in-creases every year. We do not envy the editor his task of getting some forty contributors up to sending in their articles on the progress of medicine during the year in time to publish the annual, so that the reader can have it in his hands at the dawning of the next, but he certainly accomplishes it with great The list of contributors strikes us more by the inclusion of new names than by elimination of old ones, but it undoubtedly represents a strong and a catholic staff. The illustrations are well up to the best level of the art of reproduction in its modern developments, and such plates as the coloured ones of gastroscopic examination and diaphanoscopy of the eye leave nothing to be desired.

In this new volume of "The Medical Annual," Dr. Watson presents a series of plates to illustrate his article on "Nasal Accessory Sinuses" which in themselves are a joy to look upon. One of the articles which will attract most interest is that by Mr. Sampson Handley on his operation for lymphatic obstruction. Most surgeons are aware that Mr. Handley's method consists in burying a number of silk threads in the tissues leading from the affected area to a place where the lymphatic circulation is in active progress. The immediate success of the manœuvre is striking in its rapidity and efficacy, and Mr. Handley estimates that its effects should last for ten years. New methods of diagnosis and treatment of syphilis have led to an interesting article by Mr. Thomson Walker, and practitioners will do well to make its contents part of their own knowledge. Professor Lucas-Championnière has dealt in a most valuable way with the modern treatment of fractures, and, happily for patients, the modern treatment is very different from the old.

An important work, having for its object the elucidation of the working of the Workmen's Compensation Act from medico-legal standpoints is announced by Messrs. Bailliere, Tindall and Cox to be ready in a few days. There are many obscure points in the working of this Act, and medical men frequently find themselves in almost insuperable difficulties regarding them. them. To facilitate matters, chapters have been written by about thirty well-known medical authorities as to the effect of injuries to the various organs of the human body, whilst the legal side and the editorial work has been entrusted to the able hands of Mr. Douglas Knocker, barrister-at-law.

THE Alexander Memorial Prize, consisting of £50 and a gold medal, is awarded every third year to writer of the best essay on a subject connected with military medicine, surgery or hygiene. The subject for the next prize essay is "Tropical Abscess of the Liver." The subject may be treated either from a clinical or an atiological standpoint, and the essay must be revised. must bear evidence of original observations. Further particulars may be obtained on application to the Secretary of the Prizes Committee, Royal Army Medical College.

MESSRS. MACMILLAN AND Co. announce as in course of publication a second edition of "A New System of Medicine," by many writers, edited by Sir Clifford Allbutt, K.C.B., and Dr. Rolleston. Mr. H. K. Lewis announces a "Manual of Operative Surgery," by Dr. John F. Binnie, Professor of Surgery in Kansas Medical College, in two volumes, the first of which—"Operations on the Head, Neck, Nerves, Trunk, Genito-Urinary Organs, etc."—is now ready, and is complete in itself.

Dr. RABAGLIATI, of Bradford, sends us a booklet entitled "Evolution, False and True: A Twentieth Century Message." The tiny venture is in verse—very good verse some of it—a portion being devoted to the nineteenth century and the remainder to the twentieth. In it our confrère endeavours to combat Darwin's theory of the origin of species, and from strong reli-gious conviction relies on "the simple creed that God creates."

We understand that a new and revised edition of Dr. Samuel West's thoughtful work on "Diseases of the Organs of Respiration" is about to be published by Messrs. Chas. Griffin and Co., Limited. The work was so highly appreciated on its first appearance that it was felt a new edition would be called for at no distant date. The author has extended the text and, by careful revision. has brought the book up-to-date.

A FIFTH edition of that classic on "Diseases of the Ear," by Professor Politzer, reached us as we were going "to press." At such short notice we can only announce the fact, merely adding that it has been translated at the author's request, as was the previous edition, by two of his former pupils, Drs. Ballin and Heller, and appears to be more than a revised version, Heller, and appears a re-written book, in fact.

WE are not surprised to see still another edition of Mr. Lockhart Mummery's "The After-Treatment of Operations," announced. This unpretentious yet Operations," eminently practical work attracted immediate attention on its inception, and a second edition was quickly called.

#### NEW BOOKS AND NEW EDITIONS.

THE following have been received for review since the publica-tion of our last monthly list:—

FELIX ALCAN (Paris).

Le Disbete Sucre. Par R. Lepine. Price Fr. 16.

EDWARD ARROLD (London).

Lectures on Diseases of Children. By Robert Hutchison,

M.D. F.R.C.P. Second Edition, revised and enlarged. Illustrated. Pp. 426. Price 8s. 6d. net.

JOHN BALE, SONS AND DANIELSSON. LTD. (London). Tuberculin in Diagnosis and Treatment. By Dr. Bandelier and Dr. Roepke Translated from the Second German Edition, by Egbert C. Morland, M.B., B.Sc.Lond., M.D.Berne. Pp. 582. Price 7s. 6d. net.

Notes and Thoughts from Practice. By W. J. Tyson, M.D., F.R.C.P., F.R.C.S. Pp. 95. Price 2s. 6d. net.

Rational Immunisation in the Treatment of Pulmonary Tuberculosis and other Diseases. By E. C. Hort, B.A., B.Sc., M.R.C.P. Pp. 75. Price 3s. 6d. net.

Notes on Soured Milk. By Elie Metchnikoff, of the Pasteur Institute, Paris. Pp. 20. Price 1s. net
A History of the Reading Pathological Society. By Jamieson B. Hurry, M.A., M.D. Illustrated Pp. 179. Price 7s. 6d. net.

BAILLIERE, TINDALL AND COX (London).
Operative Nursing and Technique. By Charles P. Childe, B.A., F.R.C.S.Eng. Pp. 224. Price 3s. 6d. net.

Aids to Medicine. By Bernard Hudson, M.D.Cantab., M.R.C.P. Lond. Price, cloth, 3s. net; paper, 2s. 6d. net.

The Nauheim Treatment of Diseases of the Heart and Circulation. By Leslie Thorne Thorne M.D., B.S.Durham, etc., etc.

Aids to Forensic Medicine and Toxicology. By Wm. Murrell, M.D. F.R.C.P. Seventh Edition. Pp. 123. Price, cloth, 2s. 6d. net; Paper, 2s. net.

Lectures to Practising Midwives. By Victoria E. M. Bennett, M.B., B.S.Lood., D.P.H.Cambs. With Preface by Mrs. Mary Scharlieb, M.D., M.S.Lond. Illustrated. Pp. 256. Price 4s. net.

Translated at the personal request of the Author, and Edited by Milton J. Ballin, Ph.D., M.D., and Clarence L. Heller, M.D. New (Fifts) Edition, entirely re-written. Illustrated. Pp. 852. Price 25s. net.

Cassell And Co., LTD. (London).

A Manual of Operative Surgery. By Sir Frederick Treves, Bart., G.C.V.O., C.B., LLD, F.R.C.S., and Jonathan Hutchingon, F.R.C.S. vol. I. Third Edition. Illustrated. Pp. 775. Price 18s. net.

Chuschll, J. and A. (London).

A Manual of Operative Surgery. By Sir Frederick Treves, Bart., G.C.V.O., C.B., LLD, F.R.C.S., and Jonathan Hutchingon, F.R.C.S. vol. Ind. A. (London).

Southall's organic Materia Medic 462 THE MEDICAL PRESS.

Sprains and Allied Injuries of Souther. By M. H. Main. Price 10ckg. M.D., M.C., F.R.C.S. Illustrated. Pp. 241. Price 7s. 6d. net
WILLIAM HODGE AND CO. (Edinburgh).
The Alcohol Case. (The Summing Up.) By Father Power, S.J. Pp. 48. Price 6d. net.
H. K. Lewis (London).
The Operations of Aural Surgery. By C. Ernest West, F.R.C.S., and Sydney R. Scott, M.S., F.R.C.S. Illustrated. Pp. 201. Price 7s. 6d. net.
Manual of Operative Surgery. By John Fairbairn Binnie, A.M., C.M.Aberd. Vol. 1. Fourth Edition, revised, enlarged, and illustrated. Pp. 832. Price 14s net.
E. AND S. Livinostone (Edinburgh).
The Studenta Pocket Prescriber. By H. Aubrey Husband, M.B., C.M., etc., etc. New Edition. Pp 175, Price 1s. 6d. net Longmans, Green and Co. (London).
Lectures on the Use of Massage and Early Movements in Recent Fractures. Sir Wm. H. Bennett, K.C.V.O., F.R.C.S., Fourth Edition. Hustrated. Pp. 134. Price 6s.
MACMILLAN AND CO., LTD. (London).
Home Nursing, with Notes on the Preservation of Health. By Isabel Macdonald. Illustrated. Pp. 326. Price 2s. 6d. net.
Thomas Nelson and Sons (London).
The Children's Charter: A Sketch of the Scope and Main Provisions of the Children Act, 1908. By M. R. Inglis, with a preface by The Rt. Hon. Herbert Samuel, M.P. Pp. 64. Price 6d. net.

James Nieber and Co., Limited (London).
Essays on the Position of Abdominal Hysterectomy in London. By John Bland-Sutton, F.R.C.S.Eng. Pp. 90. Price 2s. 6d. net.
Press of American Medical Association (Chicago).

PRESS OF AMERICAN MEDICAL ASSOCIATION (Chicago).

New and Non-official Remedies, 1909. Pp. 167. Price, paper,

Golden Rules of Amesthesia. By R. J. Probyn-Williams, M.D.

Third Edition, revised. Pp. 67. Price 1s.

Health, Morals, and Longevity. By George Gresswell, M.A.

Oxford and Cape, L.R.C.P., and S.Edin., L.F.P.S.G., and Albert Gresswell, M.A., M.D., Oxford, M.R.C.S., F.R.S.M., Pp. 229. Price 5s. net.

#### MEDICAL NEWS IN BRIEF.

#### Prevention of Ophthalmia.

A CONFERENCE of Medical Officers of Health of the district round Birmingham was held at Hanley on April 29th, to consider the question of the prevention of blindness following infantile ophthalmia. The Mayor of Hanley (Mr. G. F. Adcock) presided, and stated that that was the second meeting held as the outcome of a suggestion made by Dr. Folker at the annual meeting of supporters of the Workshops for the Blind to the effect that possibly a great number of cases of blindness were preventable if dealt with at an early stage, and that at least 40 per cent. of the cases of blindness were attributable to ignorance and neglect at that stage. At the first meeting it thought desirable that ophthalmia neonatorum should be made compulsorily notifiable, and that conference had been convened to further consider the matter with the assistance of the County Medical Officer and the Medical Officers of the district.

Mr. E. V. Greatbatch (Chairman of the Joint School Authority and of the Workshops for the Blind) said that to allow sighted infants to become blind when that to allow signed infants to become blind when that blindness could be prevented was a wasteful, extravagant, costly, and cruel way of dealing with humanity. What was wanted was to get the Local Government Board to make notification of ophthalmia in infants compulsory, so that the cases might be dealt with immediately. Dr. H. H. Folker advocated com-

pulsory notification.
Dr. G. Reid (County Medical Officer) explained the difficulties in the way of action in the matter without an alteration of the law, but suggested that a deputa-tion might be appointed to confer with the President of the Local Government Board.

#### Durham County Sanatorium for Women.

On May 1st there was inaugurated an important phase of the work of the Society for the Prevention and Cure of Consumption in the County of Durhamnamely, the opening of the Sanatorium for Women, which is situated at Wolsingham. The ceremony was performed by the President of the Society. Lord Barnard. The Society was founded in 1898, and the Stanhope Sanatorium was opened in May, 1900. This sanatorium provides accommodation for 31 male and 14 female patients. For some years the committee have felt, in view of the increasingly large number of applications for admission, that it was desirable to acquire another building, retaining the Stanhope Sanatorium for male patients, and devoting the new building to the treatment of women. With this end in view, funds have been accumulated, and the Leazes House, Wolsingham, a beautifully situated mansion standing in 5 acres of grounds, together with an adjoining field of 10 acres, has been purchased by the committee. It is estimated that a sum of £1,000 will be required in order to defray the cost of necessary alterations and furnishing, and it has been suggested that it would be a graceful and most appropriate seracquire another building, retaining the Stanhope Sanathat it would be a graceful and most appropriate service if the ladies of the county would undertake to provide this sum for their suffering sisters.

The new sanatorium at Wolsingham will provide accommodation for 28 women patients, and the committee actions that it like Contests will be considered.

mittee anticipate that it-like Stanhope-will be practically self-supporting by means of patients' contributions, annual grants from local authorities, and workmen's subscriptions.

#### Esperanto in Ireland.

DR. G. JAMESON JOHNSTON has been appointed Consul for Ireland for the Universal Medical Esperanto Association, and also "Deligito" for Dublin for the Universala Esperanto-Asocio. He has already obtained a number of new members for both Associations, and we are asked to point out that anyone interested in the movement can obtain all information by applying to him at his residence. by applying to him at his residence, 13 Lower Fitz-william Street, Dublin. We understand that an attempt is to be made to induce the Royal Colleges to place Esperanto on the list of optional subjects for their preliminary examination.

#### Glanders in London.

TWENTY-Two summonses, II against the London Parcels Delivery Company, Limited, and II against Mr. Clampett, their horse superintendent, were heard on April 29th at Bow Street.

The complaint was that the company, which owns 600 or 700 horses in London, had failed to notify one case of glanders and several of suspected glanders at their stables at Hampstead, Stepney, Eltham, and Fetter Lane.

Counsel stated that the matter was brought to notice by the death of an employee named Davis in February from glanders—a terrible disease, extremely catching, from which victims hardly ever recovered.

The defence was that the company was unaware of the existence of the disease, which was an insidious one, and sometimes existed without external symptoms. Two summonses were withdrawn, and the remainder were adjourned.

#### Royal Institute of Public Health.

A COURSE of lectures on "Army Sanitation" has been arranged for delivery at this Institute on every Wednesday, commencing May 12th till June 16th inclusive, at 6 p.m. each day. The first lecture will be delivered by Surgeon-General G. J. H. Evatt, C.B., M.D., on "The Officer and his Duties towards the Well-being of the Soldier under his Command," followed by "The Practical Sanitation of Camps," by Lieut.-Col. R. H. Firth, F.R.C.S.; "The Essential Principles of Sanitation in the Field," by Lieut.-Col. C. H. Melville, M.D.; "Hospital Work in War," by Lieut.-Col. R. J. S. Simpson, C.M.G., M.B.; "The Bacteriology of Diseases Common to Armies in the Field," by Professor R. Tanner Hewlett, M.D., F.R.C.P.; the final lecture being on "Inoculation Methods for the Prevention of the Diseases to which the Soldier is Liable," by Lieut.-Col. S. Monckton Copeman, M.D., F.R.S.

The Hon. Secretary, Mr. James Cantlie, F.R.C.S., asks us to announce that all officers of the Territorial Force will be cordially welcomed.

#### Bolingbroke Hospital.

The annual general meeting of the Governors of this Institution was recently held at the hospital, Wandsworth Common, Canon Erskine Clarke, Vicar of Battersea, presiding. The chairman said that subscriptions during the year had amounted to only £525, but there had been a considerable income from donations and legacies. Increased subscriptions were urgently needed, since the cost of maintaining the accident branch of the hospital exceeded £2,000 per annum. Dr. Howell, a member of the Wandsworth Borough Council, referred to the Weir bequest, and said it was difficult to understand why the Wandsworth Borough Council opposed its application to the Bolingbroke Hospital. Last year the cases from the borough of Wandsworth outnmbered those from Battersea. The report and financial statement were adopted.

#### The Medical Defence Union.

THE annual general meeting of the Medical Defence Union, Limited, will be held at the Medical Library. University College, Bristol, by the kind permission of the authorities, on Thursday, May 27th, at 4.30 p.m., when the annual report will be presented and the usual statutory business carried out.

#### Che'sea Hospital for Women.

By the kind permission of Mary, Countess of Ilchester, a concert in aid of the Chelsea Hospital for Women will be held in the Garden Ball Room at Holland House, Kensington, on Friday, June 11th, at 3 p.m.

#### Royal College of Physicians of London.

At the meeting of the Council of the College, the L.R.C.P. was conferred upon the following or candidates who had passed the Final Examination in Medicine, Surgery, and Midwifery of the Conjoint Examining Board:

Adolphe Abrahams, B.A.Cantab.; Harold W. L. Allott, Mukhtar Ahmed Ansari, B.A., M.B., Ch.B., Richard R. Armstrong, B.A., Cantab., John Lee Atkinson, Kenneth J. Aveling, Bertram F. Bartlett,

Phirozshah B. Bharucha, L.M., Harold E. Bloxsome, Trevor L. Bomford, William F. Bowen, Harold Bowring, B.A. Cantab, Eldred C. Braithwaite, M.B., B.S. Durham, Thomas F. Brown, William H. Butler, Frederick G. Caley, B.A. Cantab, Frederick G. Cawston, B.A. Cantab, Howard D. Clapham, Alfred J. Clark, B.A., Cantab, John P. Clarke, Kenneth Comyn, Reginald B. Dawson, L.M.S.S.A., Canut Deuntzer, James R. Dick, B.A. Cantab, Josiah R. B. Dobson, Malcolm Donaldson, B.A. Cantab, Archibald W. Duncan, George H. Dunn, M.A. Cantab, Leslie W. Evans, Thomas Evans, Philip C. Field, Howell W. Gabe, Edward B. Garrard, Paul K. Gilroy, B.A. Cantab, Claude Gouldesbrough, M.A. Oxon, George A. Greaves, Harry S. Hall, B.A. Cantab, David J. Harries, B.Sc. Wales, Thomas Harrison, M.B., Ch. B. New Zealand, Henry Hudson, Edward P. L. Hughes, Robert H. Hutchinson, B.A. Cantab, Victor P. Hutchinson, Robert S. Ingersoll, Roger P. Jones, Charles F. V. Kebbell, Latafat Husain Khan, Henry G. Kilner, Septimus J. Lee, Arthur S. MacNalty, Reginald H. Mawhood, B.A. Cantab, James K. Milligan, Howard E. H. Mitchell, Edwin B. The following passed the Second Professional

The following passed the Second Professional Examination:—William Millerick, Cyril S. Owen, Arthur L. Edwards, James Macrae, James A. Hutchinson, Furdon F. Keravalla, Henry R. Macnab, Colin Hunter, and Amabile Caruana.

The following passed the Third Professional Examination:—Hugh F. Williams, James Blackburn, Patrick Walsh, Cornelius A. O'Driscoll, John W. Robertson, Dinshaw Bhicaji Gazdar, William Browne, Erach D. Shroff, Francis P. Quirk, Nariman Byramji Mehta, William M. Thomson, Ralph C. Fuller, and Seringapatam N. S. Aizangar.

The following passed the Final Examination, and were admitted L.R.C.P.E., L.R.C.S.E., and L.F.P.S.G.:—David George Lindsay, Glasgow; Nariman Byramji Mehta, Bombay; John M'Call, Tasmania; Vaman Gopal Gokhale, Kolhapur, India; Henry Eric Swan, Ceylon, and Isabel Pulteney, Ashley, Northants.

THE Royal College of Physicians of London has enacted the following by-law relating to the admission of women to examination for the college diplomas:—
"Women shall be eligible for admission as licentiates and members of the college and for a grant of a diploma in public health on the same terms and conditions as men; and so far as is necessary to give effect to this by-law, words in the by-laws and regulations importing the masculine gender shall include females, and all proper alterations shall be made in the forms of the letters testimonial, and the licence granted by the College.

#### **NOTICES TO** CORRESPONDENTS.

CORRESPONDENTS requiring a reply in this column are par-ticularly requested to make use of a Distinctive Signature or Initial, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much con-fusion will be spared by attention to this rule.

#### SUBSCRIPTIONS.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada. ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

ADVERTICEMENT'S.

ADVERTICEMENTS.

ADVERTIGEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.;
Quarter Page, £15s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 53 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), &c. 6d. per insertion; 6d. per line beyond.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office, When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

MRS. EDWIN B. (London).—Every year a certain number of London working boys are sent away to seaside camps by an association organised for that purpose. Each boy has to pay a certain sum towards maintenance. Particulars can be obtained of the Secretary, Mr. F. A. Bloxbam, 23 Northumberland Avenue, London, W.C.

PENDRAGON (Somerset).—Many medical men have been well-

London, W.C.

Pendragon (Somerset).—Many medical men have been well-known figures in the hunting field, as, indeed, they have at one time or another in almost all forms of British sport. It is impossible to give any exact estimate, but many a man of good constitution is able to hunt comfortably up to seventy, or even eighty vears of age. Fatalities in the hunting field are inseparable from the pursuit. Happily, however, in many severe injuries to the spinal column the resources of modern surgery are able to save life, and even to restore, more or less, completely to health.

ALL THE DIEEPBRAGO

ALL THE DIFFERENCE Cream, of course, suggests a churn, "Creamatorium"—an urn. In the first, oream agitated, In the latter, folks cremated. Some who never earned their bread Have their ashes "urned" instead.

A. D.

RESTICANA.—A cottage hospital, even if small, should be provided with an operating room, that is to say, if it is to be regarded as properly equipped for its purpose. There is no need for the elaborate fittings of a first-rate hospital, but there should be proper washing basins, good hot and cold water supply, irrigating and sterilising apparatus, operating table, trays and cupboards for instruments, and the walls and floor should be smooth and non-absorbent. An estimate on any scale can be got from the chief surgical instrument makers.

DR. J. E. S.—The remedy we have found of greatest service in

DR. J. E. S.—The remedy we have found of greatest service in those cases of obstinate dyspepsia, which, as the one now under consideration, seem almost intractible, is Schacht's "Bisedia," a combination of pepsin, bismuth, morphia, acid hyd., and nucle your. It seems especially valuable in those cases where gastric pain is so distressing after a meal.

#### Meetings of the Societies, Tectures, &c.

WEDNESDAY, MAY 5TH.

WEDNESDAY, MAY 5TH.

MEDICAL GRADUATES' COLLEGE AND POLICLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. J. Cantile: Clinique (Surgical), 5.15 p.m.: Lecture: Mr. Bland-Sutton: The Baneful Effects of Pregnancy on Uterine Fibroids.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Weles's General Hospital, Tottenham, N.).—Clinics: 2.30 p.m.: Medical Out-patient (Dr. T. R. Whiphaim); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks).

Thursday, May 6th.

Ophthalmological Society of the United Kingdom (11 Chandos Street, Cavendiah Square, W.).—3 p.m.: Card Specimens will be shown by Major R. H. Elliott, I.M S., Mr. S. Stephenson, Mr. G. W. Roll, and others. 8.30 p.m.: Pr. G. Carpenter: A Short Note on Tubercle of the Choroid with an Account of a Recent Case. Mr. M. Davidson and Mr. A. Lawson: A Case of Spring Catarrh Treated and Cured by Radium. Mr. R. R. Cruise: The Abuse of Atropin in Refraction Work. Mr. S. Mayou: On, the Disappearance of the Iris from the Papillary Area following Injury. Mr. W. H. H. Jessop: The Report of the International Committee on the Unification of the Notation of Visual Acuity and of the Meridians of Astigmatism.

Norh-East London Clinical Society (Prince of Wales's Hospital, Tottenham, N.).—4.15 p.m.: Clinical Cases.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chemies Street, W.C.).—4 p.m.: Sir Jonathan Hutchinson: Clinique (Surgical). 5.15 p.m.: Lecture: Dr. G. H. Savage: The Feeble minded and their Care.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynscological Operations (Dr. A. E. Giles). Clinics: Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. H. W. Carson); X-Bays. 5 p.m.: Medical In-patient (Dr. G. P. Chappel).

ROYAL SOCIETY OF MEDICINE (LAENNOOLOGICAL SECTION) (20, Hanover Square, W.).—5 p.m.: Dr. Dundas Grant: Two Cases. Dr. Donelan: (1) Laryngeal Tuberculosis in a Man, aged 43; (2) Deflection of Septum in a Boy, aged 13: Question of Resection; (3) Recurrent Occlusion of Naris. Mr. Herbert Tilley: Chronic Suppuration in the Left Sphenoidal Sinus; Recovery Dr. Jobson Horne: Fination of Right Vocal Cord, of Intermittent Occurrence. in a Man aged 40. And other Cases.

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Field: W.C.).—5 p.m.: Prof. Keith: On Specimens illustrating Malformations of the Nock. (Museum Demonstration.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. S. Stephenson: Clinique (Eye).

CENTRAL LONDON THROAT AND EAR HOSFITAL (Gray's Inn Road, W.C.).—3.45 p.m.: Lecture: Dr. A. Wylie: Larynx.

ROYAL SOCIETT OF MEDICINE (OTOLOGICAL SECTION) (20, Hanover Square, W).—10 a.m.: Cases and Specimens: Mr. C. C. West: Further notes on Case of Caronoms of the Ear. Dr. Adolph Bronner: Cholesteatoms of the Ear treated with Ensymol. Mr. R. Lake: Case of Epileptiform Attacks of Labyrinthine Origin, and Other Cases. Mr. Hunter Tod and Mr. A. L. Whitehead will also show Cases and Specimens.

## Appointments.

DE SOUZA, D. H., M.D., M.R.C.S., L.R.C.P., House Physician to University College Hospital.

FERNIE, F. E., M.R.C.S., L.R.C.P.Lond., Certifying Surgeon under the Factory and Workshop Act for the Stone District

under the Factory and Workshop Act for the Stone District of Stafford.

Hancock, W. Ilbert, F.R.C.S.Eng., Assistant Surgeon to the Royal London Ophthalmic Hospital (Moorfields).

Hogarth, Robert George, F.R.C.S.Eng., one of the Medical Referees under the Workmen's Compensation Act, 1906, for County Court Circuit No. 18, and to be attached more particularly to Nottingham, Newark, and Bingham County Courts.

Kauffmann, Otto Jackson, M.D.Lond., one of the Medical Referees under the Workmen's Compensation Act, 1906, for County Court Circuit No. 26.

Maitland, Latton Pelham, M.B., B.S.Lond., Medical Registrar to Charing Cross Hospital.

#### Vacancies.

Middlesex County Asylum, Napsbury, near St. Albans.—Fourth Assistant Medical Officer. Salary, £160 per annum, with furnished apartments, board, washing, and attendance. Applications to the Medical Superintendent. Victoria Hospital, Folkestone.—House Surgeon. Salary, £100 per annum, with board, residence, and laundry. Applications to the Scoretary.

Applications to the Medical Superintendent.

Victoris Hospital, Polkestone.—House Surgeon. Salary, £100 per annum with board, residence, and laundry. Applications to the Secretary.

Royal South Hants and Southampton Hospital.—House Physicias. Salary, £100 per annum with rooms, board, and washing. Applications to T. A. Fisher Hall, Secretary.

Newcastle-upon-Tyne Crit Lunatic Asylum, Gosforth, Newcastle-upon-Tyne.—Second Assistant Medical Officer. Salary, £140 a year, with furnished apartments, board, and laundry. Applications to Dr. Callcott, Medical Superintendent.

Stockton and Thornaby Hospital, Stockton-on-Tees.—House Surgeon. Salary, £160 per annum, with residence, board, and washing. Applications to H. G. Sanderson, Secretary, 63 High Street; Stockton-on-Tees.

Suffolk District Asylum, Melton.—Second Assistant Medical Officer. Salary, £160 per annum, with board, furnished apartments, attendance, and laundry. Applications to the Medical Superintendent.

The Hospital for Sick Children, Great Ormond Street, London. W.O.—House Surgeon. Salary, six months, £30, washing allowance £2 10s., and board and residence in the Hospital. Applications to the Secretary. (See advt.)

#### Births.

CARTER.—On April 29th, at 4 Edgar Buildings, Bath, the wife of Stuart Uarter, L.D.S., R.O.S.Eng., a son.
KEMPTHORNE.—On April 25th, at Mussoorie, India, the wife of Capt. G. A. Kempthorne, R.A.M.O., of a daughter.

#### Marriages.

ROE-WALKER.—On April 29th, at S. Luke's, Nightingale Lanc. London, Rev. Everard V. Roe, B.A., R.N., fourth son of Edwin H Roe, M.R.O.S., and Mary Edith Dorothea, second daughter of the late Edward Walker, M.A., Barrister-at-Law.

#### Deaths.

MALLARD.—On April 27th, at Holly Cottage, Pine Bidge, Farnham Kate, the wife of F. B. Mallard, M.B.C.S.Eug., of Hammersmith.

An Ideal Tonic in Convalescence.

An Active Aid to the Digestion of Farinaceous Foods.

'Byno' Hypophosphites may be taken when the digestive organs are weak and impaired, and when ordinary tonics cannot be tolerated.

THE constituents of 'Byno' Hypophosphites ensures the effectual combination required in a perfect tonic. This combination, though somewhat complex, is in practice most successful, and 'Byno' Hypophosphites will be found much superior to the official syrup of which it is the analogue. It stimulates the appetite whilst aiding digestion; it conserves and invigorates the nervous system.

PRACTICAL CLINICAL EXPERIENCE of many years has proved that what theoretically is expected of 'Byno' Hypophosphites by reason of its composition is fully justified. It is, as the *British Medical Journal* says,

"One of the Most Popular Tonics of the Day."

Furnished in

# ANASARCIN

(Contains in combination the active principles of Oxydendron, Arboreum, Sambucus Canadensis & Urginea Scilla-)

RELIEVES

Valvular Heart Trouble by reducing number of heart beats, giving the heart rest, increasing the force of the Systole, causing valves to close more thoroughly, thus preventing regurgitation, relieving the dyspnœa, and increasing heart nutrition.

Cirrhosis of the Liver by equalising the circulation, dilating the arterioles, thus relieving obstruction in the branches of the hepatic artery and portal radicles, securing better circulation in the liver and more nutrition to the cells and interlobular connective tissue.

Ascites and Anasarca by causing resorption of the effused serum into the circulation, whence it is easily eliminated with salines.

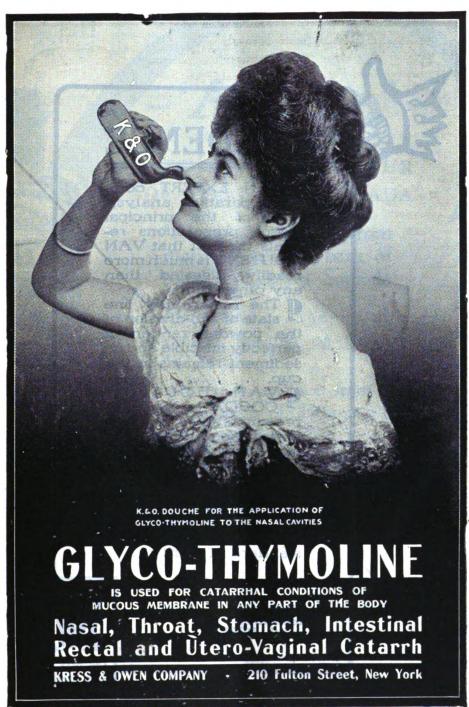

Exophthalmic Goitre by its inhibitory power over the cardiac fibres of the pneumo-gastric, controlling the heart's action indefinitely without detriment, thus preventing enlargement, or restoring to normal if already enlarged, the thyroid arteries and the vessels behind the globes which cause prominence of the eyeballs and enlargement of the thyroid gland, both of which are consecutive to the cardiac disorder.

Bright's Disease by its power to relieve distal engorgements through its wonderful equalising effect on the circulation, dilating the arterioles and establishing a normal physiological balance between arterial and venous systems.

Sample and Literature to Physicians.

Examined and approved by the Institute of Hygiene, 34 Devonshire St., Harley St., W., where this preparation can be seen, and its properties and value can be explained.

# **EVIDENCE**

N EXPERT comparative analysis of the principal Cocoa preparations reveals the fact that VAN HOUTEN'S is much more readily, digested than any other kind.

The remarkably fine state of sub-division of the powder renders it perfectly miscible and no sediment remains in the cup.

VAN · HOUTEN'S COCOA is therefore pre-eminently suitable for invalids, and does not tax the weakest digestive organs. It never varies in quality and can be confidently recommended as a nourishing, sustaining, and strengthening beverage of the highest standard of purity.

80 years reputation as "the BEST."

# LISTERINE

## The standard American antiseptic for internal and external use

Awarded Gold Medal (Highest Award) Lewis & Clark Centennial Exposition, Portland, 1905; Awarded Gold Medal (Highest Award) Louisiana Purchase Exposition, St. Louis, 1904; Awarded Bronze Medal (Highest Award), Exposition Universelle de 1900, Paris.

The word Listerine assures to the Medical Profession a non-poisonous antiseptic of well proven efficacy; uniform and definite in preparation, and having a wide field of usefulness.

Listerine represents the maximum of antiseptic strength in the relation that it is the least harmful to the human organism in the quantity required to produce the desired result; as such, it is generally accepted as the standard antiseptic preparation for general use, especially for those purposes where a poisonous or corrosive disinfectant can not be used with safety. It has won the confidence of medical men by reason of the standard of excellence (both as regards antiseptic strength and pharmaceutical elegance), which has been so strictly observed in its manufacture during the many years it has been at their command.

The success of Listerine is based upon merit, i.e., the best advertisement of Listerine is Listerine.

# LAMBERT PHARMACAL COMPANY,

ST. LOUIS, U.S.A.

In combating serious illness, it is doubly important to be assured that the patient is supplied with genuine Listerine, as the substitutes sometimes offered by the trade are generally of undetermined antiseptic strength, and too often worthless for the purposes for which they are required.

#### Notes and Comments.

An interesting variation from the A Strike usual run of strikes is reported to be of taking place in the village of Saint-Patients. Sauveur, Canton de l'Yonne. The district, it seems, is served by two medical practitioners who have recently agreed with each other to raise their fees to the extent of a third. Knowing what most medical fees on the Continent amount to, we cannot think that when enhanced by 33 per cent. they would be very ruinous, but Saint-Sauveur, having always enjoyed the privilege of cheap medical attendance, is aghast at being called upon to pay more than the modest sums usually demanded of it. The neighbours, therefore, have met and informed the doctors that they will stand no advance in prices, and that in future they decline to be attended by such avaricious

gentlemen. In the meantime, they are trying to do without medical attendance, and to import a "blackleg" who will carry on practice at the old rate. Undeterred by the prospect, the doctors have decided on a "lock-out," and matters seem to have wallowed to an impasse. Although we are not in a position to judge of the capabilities of the inhabitants of Saint-Sauveur to pay more than they have been doing for medical attendance, we gather from much that has taken place in this island that the doctors have probably been imposed upon whole-sale, and our sympathies would therefore naturally be with them. This form of strike is a novel one, and its issue will be a matter of no little importance, on the question of principle alone.

Steamboats on

From the public health point of view it is highly regrettable that the London County Council persist in the Thames. refusing to run a summer service of steamboats on the Thames. It is

difficult to steer clear of the whirlpool of municipal politics in speaking of this matter, as it has divided the Council on the exact line of party cleavage. That this should be so is much to be deprecated. When the steamboat service was started three years ago, a new means of pleasure and recreation was afforded to the toiling millions on the banks of the river from Battersea to Greenwich. The popular fares and the comfortable boats tempted thousands of the poor from their stuffy homes in courts and alleys on Saturday and Sunday afternoons in the summer, and the gain to their health was no whit less than that provided by an afternoon in the parks or the country. The argument that the service did not pay deserves careful consideration, and we are not prepared to deny that the administration was not over-sanguine in its calculations. With the experience now gained it ought to be possible to put on a limited service which would pay its way, and even if there were a deficit, it has to be remembered that large sums are still annually payable for interest and sinking fund for the service of the debt incurred in initiating the service. Because the steamers are not running it does not mean that expenses thereby cease. Moreover, in matters of public health we have never yet heard it asserted that pure commercial considerations alone should count, as apart from sewerage, asylums, and similar heavy items of expenditure, the cost of the public parks is very large, and begrudged, as far as we know, by nobody. It is pitiable that these fine steamers which are capable of giving so much health and pleasure to thousands should be sold out of the country for a mere song.

MR. LUPTON tried to "draw" Mr. Vaccination Burns last week on the subject of and the Bristol vaccination, and, boomerang-like, Outbreak. the effort recoiled, to his extreme

discomfiture. The interrogation he put to the President of the Local Government Board was whether, during the recent outbreak at Bristol, small-pox had shown any partiality for unvaccinated children. Now Mr. Lupton knew the numbers attacked had been very small, and in a fairly well-vaccinated community like Bristol the great probabilities were that the number of children under fourteen who were attacked would have been the elder vaccinated ones, in whom the effect of the inoculation was beginning to wear off. As it happened, however, Mr. Burns was able to tell the same tale of the little Bristol outbreak as has been told by every epidemic since vaccination was introduced, namely, that of high incidence and fatality in unvaccinated children, and low incidence and mild invasion in the vaccinated. The actual figures were, for children under fourteen, two abortive attacks in the vaccinated, and seven confluent attacks with three deaths among the unvaccinated. It is lamentable to think of these little ones' lives being sacrificed and the survivors scarred for life owing to the ignorance and prejudice of the antivaccination fanatics, and we only hope that when Mr. Burns gives up the reins at the Local Government Board he will be definitely convinced from his tenure of office that the immunity against small-pox conferred by vaccination is one of the greatest social benefits that medical science has yet been able to put forward.

and Drug Preparations.

THE extraordinary ramifications of The Budget modern commerce often direct the incidence of a new tax into most unexpected directions. In the case of the additional 3s. 9d. per gallon

duty on proof spirit a vast amount of inconvenience and increased expenditure will be thrown upon the shoulders of consumers. Those who are conversant

with the practical side of dispensing know that one of the most expensive items in the wholesale chemist's bill is that of the tinctures. On the principle that consumers have to pay much more than the increased cost of a supertax, the future price of medicines prepared wholly or partially by the aid of spirit will be considerably enhanced. On the other hand, it is well known that excellent and wholly satisfactory substitutes may be obtained in the shape of infusions and decoctions, or of solutions of active principles, not to mention other ways of avoiding the use of spirit. This move should please the teetotalers, who have for a long time past inveighed against alcohol in the medicine bottle. It is indeed an ill wind that blows no one good!

#### LEADING ARTICLES.

MIDWIVES AND DEATH CERTIFICATES.

THE relations between the public and the medical profession on the one hand, with the certificated midwives on the other, are at the present moment to a great extent being subjected to the investigation of a Departmental Committee. In the meantime what the local press describes as "extraordinary revelations" has taken place in a Cornish village, where two infants were buried on the strength of a document signed by a certificated midwife and handed to a gravedigger. The whole case was investigated at length by Mr. Edward Boase, the Coroner for the district, and it appears to be of such importance that no apology is needed for bringing it prominently before the attention of medical readers. Briefly stated, the facts, as elicited at an inquest held on April 20th, and reported in the Cornishman of May 1st, are that twin children—a boy and a girl—were born on April 10th at Ludgvan. The mother, the wife of a miner, was attended at her confinement by a certificated midwife, named Mary Ann Bennetts. The female child died two days after birth and was buried in the cemetery on the 12th by Henry Thomas, gravedigger, at the request of the father, there being no written authority for the burial from anybody. On this point the gravedigger stated in evidence that the father told him the child had lived a little while, but Mrs. Bennetts would furnish him with a line that would clear him. He buried the child, but was unable to get the certificate or document from the midwife because she had gone away. The other child died on April 17th and was buried on the 19th. The gravedigger said that on being asked to bury the second child, he referred the father to Mr. Rowe, the local surveyor, who had charge of the cemetery. Ultimately he buried the boy, apparently trusting to the authorisation of a certificate to be obtained from the midwife, Mrs. Bennetts, on her return. This witness appeared to be devoid of the most elementary knowledge as to his duties and responsibilities in the matter of burial. He admitted that he had buried children up to the age of six weeks on the authority of the midwife, and then remarked that "they have been still-born." These hazy notions as to the definition of "still-birth" appear to have been shared by the surveyor, Rowe, who is reported to have said he would receive a certificate from a nurse up to a week old, a period which was extended in a subsequent answer to three weeks. The surveyor said he was given to understand the girl was still-born, and he consented to the burial of the boy because he thought they would be furnished with a certificate from the nurse. The fact of the burials came to the knowledge of the local registrar, Mr. Sandoe, with whom no intimation of either the births or the deaths of the children had been lodged. A certificate was then forthcoming from the midwife, as follows:—

"Crowlas, Ludgvan.

"I, Mary Ann Bennetts, holding a certificate from the Central Midwives Board, pursuing my calling at Crowlas, Ludgvan, do hereby certify that the children of James and Beatrice Boase, of Canonstown, born April 10th, have since died owing to premature birth (time about seven months). My last visit was April 18th, 1909.—Signed, Mary Ann Bennetts, certificated midwife."

This document, it will be seen, was not dated, and, although it gave the day of birth, gave no date of death. It was, in a word, of an irregular and insufficient nature. The Coroner ordered a post-mortem examination, and the medical evidence showed healthy organs in both children-each weighing 4lbs.—with absence of food in the stomachs. In the opinion of the medical witness, death was due to congenital weakness and want of attention. The verdict returned by the jury was that the children died of congenital weakness and neglect, but not criminal neglect. They added as rider, that in their opinion Mrs. Bennetts was not fit to hold a certificate as a midwife, and that the Ludgvan Urban Council should make regulations for the control of their cemetery. The attitude taken up by the jury does not err on the side of severity. A certificated midwife who fails to call in medical advice to children in an obviously precarious condition, and who grants certificates such as that above quoted, and who admits she has never read her regulations, need not be surprised if she finds herself involved in circumstances that will deprive her of a certificate or result in even more serious consequences. Nor is the position of officials responsible for the discharge of so serious a public duty as the burial of the dead any more enviable, if they be shown to lack rudimentary information as to the legal qualifications and restrictions of his office. But the urban authorities who employed the gravedigger and the surveyor must be asked to explain their position in the affair, and to account for the absence of clear and definite rules in the conduct of a public burial ground administered under Acts of Parliament. There can be little doubt that in the past considerable laxity has prevailed in the matter of the burial of still-born infants and of those who have died soon after birth, and it may be hoped that the Ludgvan incident may not escape the attention of the Home Office and of all who are interested in the working of the Midwives Act.

## THE POOR-LAW COMMISSION AND IRELAND.

It is now about two years and a half since a Viceregal Commission, appointed to consider the question of Poor-law reform in Ireland, presented a far-reaching report which obtained an unusual degree of public support. Naturally there were

differences as regards details, but, on the whole, there was a general wish that legislation should speedily take place on the lines of the suggestions of the Commissioners. As, however, a Royal Commission was in session at the same time, whose function was to report on English and Irish Poor-law, the Government naturally refused to move until its Report also was presented. The circumstances were somewhat unfortunate for those interested in Irish Poor-law questions. On the one hand was a small Commission of three, all men intimately acquainted with Ireland and its problems, whose business was to deal with an Irish problem alone and without reference to any extraneous circumstances. On the other hand was a large Commission of eighteen, only two of whom could have any practical experience of Irish affairs. It was a Commission whose main business and interests were with English affairs, to whom the Irish problem was merely a branch of the English, and not an independent question. It will be seen, therefore, that it was hardly to be expected that a practical solution should be reached by two such bodies approaching it from different points of view, with different interests, and independently of each The result is, we fear, to postpone the The Royal Commissettlement of the question. sion is divided against itself, and while both the majority and the minority express general approval of the suggestions of the Viceregal Commission, both differ from it so widely as to render it difficult to find even the outlines of a scheme on which all could be agreed. We are at present mainly concerned with Poor-law reform in its medical aspects, and we must confess we have a decided preference for the suggestions of the Viceregal Commission over those of the majority of the Royal Commission. The Viceregal Commission recommended the entire separation from the Poor-law of the treatment of the sick, and the establishment of a State or national medical service. The Royal Commission deal with the treatment of the sick and the entire public health work of the country as part of the problem of poverty, and suggest the establishment of county medical services. Moreover, the suggestion is made that the areas of dispensary districts should, "where possible, be enlarged in view of present population." The problem of dealing with the sick poor in Ireland is, as everyone who knows the country is aware, one not so much of population as of distance. The Report fails entirely to deal with the problem of public health-one of the most pressing in the country. In short, it exhibits all the shortcomings and failings natural, indeed, almost inevitable, considering its origin. Poor-law reform in Ireland is not the same problem as in England any more now than it was seventy years ago. Each problem must be faced separately and independently. The attempt to deal with the Irish problem as a mere incident of the English can only result in failure. The Report of the Royal Commission renders the solution more difficult, in so far as it offers alternatives to the suggestions of the Viceregal Commission. The differences between the two Commissions will inevitably have the effect of making Government shy of proposing any scheme of reform.

#### CURRENT, TOPICS.

"World League" Congress.

THE fourth Triennial International Congress of the World League for the Protection of Animals and Against Vivisection is to be held in London in July, and a programme of the fare with which the gathering of the good delegates is to be provided lies before us. The President of the League is a Serene Highness, but the Vice-Presidents, though they range from Mr. Jerome K. Jerome to Mr. O'Grady, M.P., do not conjure up a title between them. This deficiency, however, is to some extent compensated for by the names appearing in the list of Vice-Presidents of the Congress, which includes the most weird assortment of aristocrats it has ever been our good fortune to read. The league has ideas of entertaining its guests which strike us as not a little odd, for at the preliminary reception the programme includes, besides music, a recitation of "Extracts from a French Play on Vivisection." If this is the most delightful form of amusement that the League can conceive, we feel our humanitarian sympathies are greatly out of touch with theirs, for we see nothing in the sacrifice of animals for the good of man that can, to a healthy mind, make the subject of a French or other kind of "play." Certain items on the programme with regard to cruelty to pit ponies, cruel traps, and so on, we are cordially in agreement with, but the bulk of the bill of fare is concerned with vivisection. General Phelps is to be congratulated on his success in dragging in his favourite subject, for he is announced to read a paper on "Connection between Vaccination and Vivisection," which seems about as ingenious a manner of getting in a hobby as if, say, Mr. Churchill were to lecture on the "Connection between Tariff Reform and Vivisection," or Mr. Bonar Law to speak on the "Relationship of Free Trade to Vivisection." However, we hardly imagine the Congress will take itself very seriously, and its vapourings are not likely to be less futile than those of its class. It is noteworthy that Mr. Coleridge and his Society appear to be eschewing the entertainment altogether.

## A Quarter of a Century's Progress in Public Health.

THE recent presentation to Dr. E. W. Hope, on the occasion of the completion of twenty-five years' service as Medical Officer of Health of Liverpool, gave rise to an interesting review of what had been achieved in public health during that period. Within the first six months of his appointment he certified more than a thousand typhus patients, but to-day that disease is almost unknown. Twentyfive years ago there was no municipal hospital, and the city had to depend entirely on the boards of guardians. Even when the infectious hospital was built it was difficult to get people to come into it-a great contrast from the present state of affairs. Notification has come on the scene, and the sanitary staff has been increased to an adequate strength by a series of Acts of Parliament, some of which originated in Liverpool. The sanitary work of the port, through which as many as 400,000 emigrants passed in a single year, and the enormous importation of foodstuffs, have led to enlarged work for

inspectors; while the task of caring for the health of the children in the schools is only just beginning, and the notification of births may lead to still more duties being cast on the health office. There is, however, one great fact to be proud of and to be seen-the remarkably-improved health of Liverpool. The improvement has taken place not only in the old parish and parliamentary borough of Liverpool, but in all the districts which had been absorbed in the municipal area. The Town Planning Act, which by the provision of wide streets and open spaces is to prevent a repetition of the errors of the past, will result in a further great development of sanitation. Moreover, people were increasingly willing to listen to advice concerning their health and that of their homes, and Dr. Hope can say that poor people are as amenable and as willing and anxious to do what they can for themselves, in a sanitary sense, as any other class. It is reasuring to find that Dr. Hope is full of confidence as to the future progress of public health.

A New Strophanthus.

A GOOD deal of interest is attached to a recent joint communication to the Royal Society of Edinburgh by Professor Sir Thomas Fraser and Mr. Alister P. MacKenzie, a Carnegie research student. Years ago the scientific examination of the arrow poison used by certain tribes of Central Africa resulted in the addition to our pharmacopæia of a most valuable heart tonic derived from strophanthus The original information and the hispidus. materials for investigation were derived from the officers of the Colonial Medical Service. There are many varieties of strophanthus ranging over a large part of West Africa-Gambia, Senegambia, Senegal, and especially in Nigeria. The new variety. the properties of which have been examined by the two authorities mentioned, is the strophanthus sarmentosus, and it is reported to have an action upon the heart closely resembling that of the strophanthus hispidus. The strophanthus sarmentosus is a creeper or vine. The seeds obtained from it are small and attractive, and in a good light exhibit a distinct velvety appearance, which distinguishes them from the seeds of all other strophanthus hitherto examined by Sir Thomas Fraser. The investigation of the new variety leads the authors to the conclusion that strophanthus sarmentosus may possibly become a remedy of much importance and value. Speaking generally, it is of interest to note the wide range of modern scientific medicine, which can extract powerful remedial drugs from so remote and apparently unpromising a source as the arrow poison of savage African tribes.

The Budget.

LAST week we referred to one point in the Budget which affects medical men-the new tax on petrol. There are some others, however, which are also of special interest to us. The first of these is the proposed licence duty on motor-cars, a duty to range from two guineas to forty-two pounds. In the case of this tax, Mr. Lloyd George proposes an exemption of half in the case of medical men. The increased tax of eightpence a pound on tobacco will, of course, tell on medical men as smokers. A considerable inconvenience to the drug trade is the additional

duty of 3s. 9d. a gallon on proof spirit, which will render it difficult for many existing contracts to be carried out. As regards income-tax, there is not much change of a nature to affect the average medical man. On earned incomes up to £2,000 a year the tax remains at ninepence, whereas on unearned incomes the tax has been raised to 1s. 2d. The abatements and allowances remain as heretofore, with the exception of a special abatement for children. In the case of persons whose total income does not exceed £500, an allowance of £10 from the assessment is to be allowed for every child under sixteen years of age. The supertax of sixpence on incomes above £5,000 will affect, we fear, but few members of the medical profession.

#### The Taxation of Motor-Cars of Medical Men.

As we anticipated in a note which we published last week under the above heading, the Chancellor of the Exchequer has intimated that medical men will not be entitled to the rebate in the duty on petrol which is granted to "commercial" users. It is thus obvious that while, on the one hand, a medical man is to be mulcted by the National Telephone Company because he is a "commercial" user of the telephone, he is also to be mulcted by the Chancellor of the Exchequer because he is not a "commercial" user of petrol. In other words, while he has to pay an additional rental for the telephone by means of which he is summoned to his patient because he uses it for business purposes, he is also to pay an additional price for the petrol by the agency of which he arrives at his patient's house because he does not use it for business purposes! Could the desire "to have it both ways' be more clearly shown. Presumably, if Mr. Lloyd George is taxed with the incongruity of his decision, he will answer that the Telephone Company is not a Government department. As it will become one in a very short time, it will be interesting to note how the Government will then regard the medical man. Will he be a commercial or a private user? In the meantime, however, we trust that medical men, both inside and outside Parliament, will try to focus the attention of Mr. Lloyd George on the gross unfairness of penalising medical men, first because they are, and secondly because they are not, business men.

Disease and History.
A FORTNIGHT ago we discussed, briefly, theinteresting theory propounded by Mr. W. H. S. Jones and Dr. Withington as to the relationship of malaria to Greek history and the Greek national character, and though we felt ourselves incompetent to decide as to the weight to be given to the actual evidence in its favour, we expressed ourselves as much interested in this new incursion of biology into the domain of history, and said that we feared it would be resented by the professional This is exactly what seems to have historian. happened, for Mr. Jones's book received a rather short review, considering its importance, in the literary supplement of The Times, and the reviewer evidently was by no means impressed with the strange doctrine. Mr. Jones wrote a carefullyargued letter in reply, but it was not inserted, and

he feels that he has been misunderstood and rather hardly done by. With this view we agree. If we look back upon the effect of plague and small-poxto mention only two prominent maladies—on the course of English history, we can realise to a slight extent what an important factor disease has been in retarding the development of people, while the effect that epidemics have had on the course of warfare might be illustrated by a hundred examples. The general advance of civilisation in the last halfcentury, since attention was paid to sanitation, has been enormous, and if tuberculosis can be eradicated in this country, there is no saying what influence may not be exerted on the race. malaria has played a big part in Greek history no one can doubt, and whether Mr. Jones be right or wrong as to the extent of the rôle he assigns to it, the matter is one which deserves the fullest ventilation.

#### Sentence for Infanticide.

LAST session the Government sustained a defeat in the House of Lords when the Lord Chancellor brought in a one-clause Bill to abrogate capital punishment being inflicted on women who killed The crime of infanticide is an their infants. The crime of infanticide is an awful one, if only for its unnaturalness, but it seems that public opinion has so far condoned it that no murderess of the class has been executed for sixty years. In these circumstances the pronouncement of the death sentence becomes a solemn farce, and we can hardly imagine anyone wishing to perpetuate such a derogation of the dignity of the Court. Last week, Lord Alverstone, as if to atone for his previous opposition to the Lord Chancellor, has brought in a Bill to enable a judge in such cases merely to record the sentence without actually pronouncing it, and this Bill passed its second reading by a large majority. small step in the right direction (though it fits very oddly into the rest of our judicial system) if the farce is to be perpetuated. We regret, for our own part that, if the death penalty is retained in our law and practice, it should be systematically withheld in cases of infanticide. With full sympathy with the seduced and deserted women, we consider that the crime, deliberately perpetrated by women who are not actuated by the impulse of shame and despair, should rank in the gravest category of murder.

#### PERSONAL.

THE EMPEROR OF AUSTRIA has conferred on Dr. Carl Harrer, Physician to the Austro-Hungarian Embassy in London, the Knighthood of the Distinguished Order of the Iron Crown of Austria.

THE Annual Dinner of the Royal Sanitary Institute was held on May 11th at the Langham Hotel, the Chair being taken by the Duke of Northumberland, the President of the Institute.

Dr. J. Lucas-Championniere, President of the International Society of Surgery, is to give the Annual Address to the Cardiff Medical Society on Friday, June 4th. His subject will be "Modern Treatment of Fractures."

THE fifth International Congress of Dental Surgery will be held at Berlin from August 23rd to 28th. The

General Secretary is Dr. Schaeffer-Stuckert, of Frankfort-on-Main. In connection with the Congress there will be an exhibition.

A FESTIVAL banquet in aid of the Mount Vernon Hospital for Consumption will be held at the Hotel Cecil to-morrow. Viscount Clifden, Deputy-Chairman of the Committee, will preside.

THE AMERICAN AMBASSADOR will preside at a Festival Dinner to be held at the Hotel Cecil on Wednesday, June 9th, in aid of the London Fever Hospital, Liverpool Road, N.

THE Annual Meeting of the Invalid Children's Aid Association will be held by permission of Lord and Lady Newlands at 16 Grosvenor Place, S.W., on Tuesday, May 25th. Field-Marshal Lord Grenfell will preside, and the Bishop of Stepney and Sir Alfred Fripp, F.R.C.S., have promised to speak.

HIS EXCELLENCY THE FRENCH AMBASSADOR, supported by the Right Hon. the Lord Mayor and the Sheriffs of London, will preside at the forty-first anniversary dinner for the benefit of the French Hospital and Dispensary to be held at the Hotel Cecil (Victoria Hall) on Saturday next, May 15th.

A SPECIAL meeting of the Dermatological Section of the Royal Society of Medicine will be held on Thursday, May 20th, at 5 p.m., when Dr. Louis Wickham, of the Radium Institute, Paris, will give a lecture and demonstration on "The Therapeutics of Radium."

.THE Annual General Meeting of the Medical Defence Union will be held at the Medical Library of University College, Bristol, on Thursday, May 27th, at 4.30 p.m., when the Annual Report will be presented and the usual business transacted.

Dr. George Charles Barnes, of Liverpool, has been appointed School Medical Officer for the township of Southport, in succession to the late Dr. Hodgson.

The Ingleby Lecture for 1909 in the University of Birmingham will be given on Thursday, May 27th, at 4 p.m., in the Medical Lecture Theatre, by Sir Thomas Barlow, Bt., K.C.V.O., M.D., F.R.C.P. The subject will be "Raynaud's Disease and Erythromelalgia: A Summary and a Review."

The remaining two lectures of the course upon "The Essentials of Physiological History" will be delivered by Dr. David Fraser Harris, M.D.Glas., B.Sc.Lond., F.R.S.E., during the present Summer Session in the Medical Theatre, University of Birmingham. They take place at 4 p.m., and are on the following dates:—May 13th, "The History of Knowledge of the Respiration"; May 20th, "The History of Knowledge of the Nervous System."

THE fourth International Milk Trade Congress will be held, under the patronage of His Royal Highness the Grand Duke Joseph, at Budapest, from the 6th to the 11th of June, this year. It is announced that some 600 persons will take part in the Congress.

THE Sanitary Committee of the Manchester Corporation have appointed Dr. Miles Bracewell Arnold, Assistant Medical Officer of Health for Blackburn, to be Medical Superintendent of Monsall Hospital, in succession to Dr. Gordon, who has resigned. Dr. Arnold was formerly First Assistant Medical Officer at Monsall Hospital for two years.

DR. CHARLES PORTER, Medical Officer of Health of Finsbury, has succeeded Dr. Meredith Young as Medical Officer to the Marylebone Borough Council at a salary of £600 per annum. Dr. Meredith Young has accepted the Medical Officership of Health for the County of Cheshire.

### A CLINICAL LECTURE

ON

#### ALCOHOLIC INSANITY.

By J. O'CONOR DONELAN, L.R.C.P.L, L.R.C.S.I.,

Resident Medical Superintendent to the Richmond District Asylum.

In to-day's lecture I intend to deal with that most important section of mental disease which is due to, or aggravated by, indulgence in alcohol. About 10 per cent. of the cases admitted to our asylums are directly caused by intemperance, while fully 15 per cent. more, though originated by some other causes, are aggravated by it. As in some of the cases of melancholia and paranoia you have seen, the patients suffering from various ill-defined, unpleasant sensations in the early stages of their disease, vainly sought relief in delusive stimulants. At first probably a sense of gratification may have been experienced, but very soon the debili-tating effects of the alcohol crushed out the resisting power of the system, leaving the mind an easy prey to the ravages of hallucinations, delusions, and general decay. No doubt many mild cases of insanity would never develop sufficiently to require asylum treatment if they could have been prevented from trying to "cure themselves," or "cheer themselves," as they express it, in the early stages of the disease.

The type of insanity resulting from alcoholism is by no means constant. Impulsiveness, exaltation, depression, stupor, etc., may be the characteristics of different cases, while epilepsy is often seen for the first time under its influence. It would seem, indeed, that whatever individual predisposition there may be to mental derangement, it is developed under the alcoholic

That hereditary tendency plays an important part in reproducing intemperance and insanity in families is generally admitted, notwithstanding the theory that acquired traits are not transmitted. On looking through our asylum records it is remarkable how often we see evidence of neurotic inheritance amongst our alcoholic cases, and also the frequency of alcoholism in the family history of our feeble-minded and insane patients, who never indulged themselves in alcohol. A kind of mutual dependence seems to exist between alcoholism and insanity, each helping the other in a vicious circle, and it may be to the advantage of our race that they lead to physical degeneration and decay -probably one of Nature's methods of getting rid of the effete.

Alcoholic insanity is classified thus:—(1) Dipsomania; (2) Acute Alcoholism (Drunkenness); (3) Delirium Tremens; (4) Mania-a-Potu; (5) Chronic

Alcoholic Insanity.

Dipsomania is a form of obsessional insanity in which the imperative idea seems to compel its victim, often against his reason and natural inclination, to

break out into alcoholic excess.

J. F. is a remarkable case of this kind. Up to 30 years of age, temperate and industrious, held a firstclass position in a large commercial establishment. He was found in his office in a profound state of intoxication. He was taken home, where he continued drinking, quite regardless of consequences, for some days, when he became violent, delusional, and afflicted by hallucinations of sight, hearing, and taste, and was then committed to the asylum, and entered as suffering from mania-a-potu. He made a good recovery, and stated that for some days he had been haunted by the idea that he should drink whisky, not that he cared for it or wanted it, but still the idea kept coming before him, and at night it kept him awake. He could think of nothing else. He said it seemed as if some misfortune would come upon him if he did not drink, so he gave way. He remembered a kind of mad delight when he did so. If he knew it was poison he said he could not have prevented himself from drinking it. It seemed as if his nerves or mind got upset before he-

took the drink. Fervently he said he would never, never drink again, and I am quite sure he earnestly meant what he said. Yet within a year he was again admitted to the asylum, and went through pretty much the same course. Since then his family had become alive to looking after him, and five years have elapsed since his last attack, but I am informed that at about the same time each year he has had to leave his work for three or four weeks, during which it was with the greatest difficulty he was restrained from "breaking out." Last month he "broke out," and now seems to be physically and mentally breaking down. Truly a case of obsessional insanity leading to drink, and drink leading to acute alcoholic mania.

Of acute alcoholism or drunkenness it is unnecessary for me to say very much, for such cases are usually dealt with by the general practitioner or the police. However, they are of interest, as they constitute miniature cases of insanity running through the several phases—elation, exaltation, depression, and stupor—in the course of a few hours. Epileptiform convulsions may be noticed in a certain number of cases, and in these the mental disturbance often lasts for some days. during which they are liable to be mistaken for epileptic insanity, and committed to the asylum. D. G. is such a case, admitted here recently as an epileptic maniac. He had been on a drinking bout, had an alcoholic (epileptiform) seizure, was sent here, where under good feeding and no drinking he quickly re-covered and will be discharged in a few days. You will observe the absence of that dull, confused apprehensive expression of countenance which is so notice-

Delirium tremens is another class—or rather degree—of alcoholic insanity, more frequently treated outside than within our asylums, and as it comes into the general hospital course I will not occupy much of your time with it. It commonly occurs in those who habitually drink freely, and who have recently been indulging to an abnormal extent. Curiously enough. we find that in many instances a distaste for drink accompanies the first symptoms of the disease, and then we are told that it was the sudden stopping of the drink that caused the upset. A chill, a shock, or an accident is often the determining cause of the break-

able in the average sufferer from epileptic mania.

Restlessness, irritability, loss of appetite, disturbed sleep with fearful dreams, soon total loss of sleep. hallucinations of a terrifying character haunt the sufferer; he is muttering, incoherent and wandering, or shouting in terror. It is difficult to fix his attention. He is liable to mistake those about him for enemies, and to make violent attacks on them under the misapprehension that they are trying to injure or kill him. The suspicions of the habitual drunkard are exag-

gerated in delirium tremens.

The physical symptoms: Face flushed, conjunctiva suffused; the tongue tremulous, thickly furred, becomes dry as the disease progresses; pulse quick, soft. and full at first, later small and irregular. The temperature may rise to 102°, but it seldom goes above 101° in uncomplicated cases. The skin is moist or perspiring, the urine scanty, dark-coloured, and

high sp. g.

In favourable cases at the end of the third or fourth day marked improvement takes place. Sleep may come on naturally and last for ten or twelve hours. when the sufferer may awaken much refreshed, the delirium and trembling are lessened and general improvement follows pretty quickly. In unfavourable cases the pulse is quick and feeble, the delirium of a

milder type, the face pale; the patient lies on his back in a semi-comatose state; convulsions may supervene, followed by exhaustion and death, or hyperpyrexia may herald the end.

Treatment.—In all cases of delirium tremens one should be prepared for and guard against heart failure, which is liable to occur even when good progress to wards recovery seems to have been made. The patient should be kept as quiet as possible in a subdued light, but total darkness must be avoided because it tends rather to aggravate the terrors. To promote sleep and build up the patient's strength are the points to be aimed at. Plenty of nourishment must be given in small quantities at a time, milk and eggs being chiefly One must be very careful in prescribing drugs. Chloral, in doses of 15 to 20 grains, may be given every six hours, and bromidia is a preparation which I find particularly useful in these cases.

It is a debatable question whether delirium tremens cases should be sent to asylums or not. No doubt we are more suitably equipped for dealing with them than general hospitals. We have trained attendants to care general hospitals. We have trained attendants to care for them, small isolation rooms, padded rooms, and grounds for air and exercise during convalescence. Against all this is the fact that certification as insane involves many disabilities; it shuts a man out of prac-fically all public services, and lowers the value of his life for insurance purposes, etc. So, all things considered, it is only in extremely violent cases that the asylum should be resorted to.

Diagnosis may be confused with acute delirious mania, but with the history of the case, and remembering that in the latter the hallucinations are not terrifying, there need be little difficulty. The delirium of pneumonia in drunkards is liable to be mistaken for it, but physical signs easily settle the question.

Mania-a-Potu occurs in persons of temperate habits who, being of neurotic taint, give way to drink for a short time. In them the intoxication seems to continue for some time. In a general way the mental symptoms resemble delirium tremens, but the expression of terror is seldom very striking, the tremor is absent or only trivial, the patient does not look ill or broken down, and he generally recovers within a few days

D. G. is a case of this class. Admitted three weeks ago for assaulting a policeman, he was in a very restless, noisy, excited state for three days, when he fell exhausted into a sleep of about 15 hours. Since then he has been quite tranquil, recognises that his mind

was upset, and says he mistook the policeman for a man he thought was on the watch to injure him.

C. E. is an interesting example of the alcoholic development of latent defects. His family history is very unfavourable. Two brothers are cases of ordinary epileptic mania, an uncle suffered from chronic delusional insanity, and other relatives are known to have been insane. He served as a soldier of good record up to five years ago when he went on a drinking bout, had an epileptiform seizure, followed by maniacal excitement and delusions of persecution against an officer. He was committed to the asylum and made a speedy recovery. He was discharged and worked as a labourer for nearly a year, when he again drank heavily for three days; as before, he had an epileptiform seizure, followed by a severe attack of mania, same delusions as previously, and made a good recovery within two months. Since then he has been discharged and readmitted three times; same course, but recovering more slowly on each occasion. He was last admitted three months ago, and you see the delusion of being followed by the officer still continues with the further development that he threatens to shoot his persecutor whenever he gets the chance. Probably the delusions have now become permanent. It is only under alcoholic influence that the seizures occur.

Closely allied to the above is the recurrent insanity of the common drunkard. He is generally one of little strength of character, he lacks inhibitory power, and is largely the creature of habit. If with drinkers, and in the way of it, he drinks; if not, he may continue temperate for a long time. As our patients express it, "I could take it or let it alone, company does it,"
"I never cared for drink." These people form an intermediate class between mania-a-potu and chronic

alcoholic insanity. The symptoms are less severe, the duration longer and the probability of recurrence much greater than in the former; the constitutional enfeeblement in early attacks is trifling, the appetite and general health recovering quickly when alcohol is withheld. Hallucinations and delusions are indefinite and very temporary, and restoration is accomplished in a week or ten days. With recurrences recovery becomes slower, delusions and hallucinations obtain a firmer hold and gradually they merge with the ranks of the chronic alcoholic maniacs and dements. unfortunate that the law does not afford some means of restraining these people in the early stages of degeneration, to protect them from their own weakness and the ratepayers from the burthen of their main-tenance when they have reduced themselves to the

stage of absolute uselessness.

Chronic Alcoholism and Chronic Alcoholic Insanity.-These are forms of mental derangement which result from steady drinking for a prolonged period. The alcohol is taken in small quantities, frequently repeated. Some confusion and impairment of memory, restlessness and irritability of temper, degradation of character, tendency to lie and use filthy language, may exist for some time before any very definite symptoms appear. Sensory and motor disturbances are frequently complained of, while gastric and digestive troubles are not uncommon. As the malady develops there is a general weakening of the intellectual faculties. The memory, particularly for recent events, becomes markedly defective, paramnesia is frequently present, attention fails, the patient grows suspicious and anxious; he is no longer able to attend to his ordinary duties, and soon he becomes incapable of looking after himself; abnormal sensations are experienced, due to the action of the alcohol on the nervous system. These are usually the starting points of hallucinations and delusions, the patient attributing them to external influences. His failure in business and general breakdown he persuades himself are caused by an enemy, and his sensations or hallucinations he believes to be a continuation of the persecution, it may be through electric or hypnotic influence. That poison is being put into his food or puffed in at the keyhole is frequently complained of; alterations of senses of taste and smell are frequently found in such cases; the delusion of poison originating in hallucination of taste, coupled with the idea of persecution. The persecutory delusions are generally in relation to some near associate, such as wife or husband. The above is practically the case of this patient M. B. To his wife, as you see, he attributes all his misfortunes. The immediate cause of this patient witch when the mode a wielant attack on of his committal was that he made a violent attack on her, under the belief that she attempted to poison him. His insane inconsistency is noteworthy. He explains His insane inconsistency is noteworthy. He explains that she put poison in his tea, but that when she looked away he exchanged her cup for his own, and although she suffered no ill-effects from drinking that which was intended for him he still believes it was poisoned.

The insanity of chronic alcoholism is liable to be mistaken for general paralysis of the insane. Exalta-tion and extravagance may occur in either, but the general paralytic tends to buy quantities of the same thing (a general paralytic lately admitted here had 26 watches on him); the alcoholic goes in for more variety. The general paralytic seldom attempts to reason or explain his delusions; he simply makes wild delusional statements of wealth or power, but does not explain much how he came by it. The alcoholic with the same delusion will explain how he came in for it, how successfully he invested it, etc.

In the chronic alcoholic the knee reflexes are usually absent or diminished; in general paralysis they may be increased, particularly in the early stages.

In both the tongue is tremulous, but in general paralysis it is ataxic also.

There is greater loss of facial expression in general paralysis. The pupils are usually unequal and often irregular in general paralysis. Headaches favour diagnosis of general paralysis.

Expression of terror is more frequent in alcoholism than in general paralysis; vivid visual hallucinations frequent in alcoholism, rare in general paralysis. The history of the case is naturally of much assistance.

If chronic alcoholism, the patient has been pretty steadily tippling for years; if general paralysis he is more likely to have developed his intemperate habits suddenly, and to have gone to extremes at once, for the general paralytic does everything in extremes.

The prognosis in such cases is unfavourable; yet we see very unpromising ones make pretty good recoveries, particularly if a first attack. Age is, of course, an important factor, those of advanced years tending to run into dementia. Profound loss of memory in a young person is unfavourable. Even in those regarded as good recoveries there is almost invariably a perceptible degree of mental enfeeblement left. I certainly cannot call to mind a case in which a patient quite regained his normal strength of mind.

The treatment consists of removal of the cause, generous feeding, which it may be necessary to forcibly administer in some cases. Sulphonal and trional are about the most satisfactory hypnotics in all alcoholic cases except delirium tremens. As convalescence progresses it is of importance to afford much outdoor exercise, cheeriness of surroundings, and generally to enkindle a bright view of life, with hope and prospect for the future. In some a sense of despondency occurs during convalescence, which must be combated, lest melancholia should supervene. As a rule, in these, as in most other forms of insanity, one of the best guides we have to gauge if recovery has taken place is to find that the patient recognises his mind had been upset, and that he fixes a period at which he found himself regaining his senses.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by George H. Savage, M.D., F.R.C.P. Lond., Consulting Physician and Lecturer on Mental Diseases, Guy's Hospital; Consulting Physician to Barlswood Asylum, &c. Subject: "The Feeble-Minded and their Care."

#### ORIGINAL PAPERS.

# RUPTURE OF THE UTERUS DURING LABOUR, (a)

By T. B. GRIMSDALE, B.A., M.B.CANTAB., Henorary Gyamoological Surgeon, Liverpool Royal Infirmary; Lecturer on Clinical Gyamoology, University of Liverpool.

RUPTURE of the uterus has been for long divided into two great classes:—

(1) Complete rupture, where the tear extends through the uterus muscle and through the peritoneum.

(2) Incomplete rupture, where the tear does not involve the peritoneum.

The present remarks will be confined to the con-

The present remarks will be confined to the consideration of complete rupture of the uterus.

The classical signs of rupture of the uterus are well known to all. There is, during labour, sudden severe pain, profuse bleeding from the vagina, great shock, and a cessation of all uterine contractions. With these symptoms anyone would at once recognise that rupture

of the uterus was a probability.

It is a very rare accident, but these classical symptoms are so alarming, and have been so graphically set before us, both in text-books and in the medical papers, that they are burned into our minds deeply and I fancy there is no one that has not pictured to himself this terrible accident, with all its dramatic surroundings, and who has not in all probability sketched out for himself some method of procedure should this accident happen to any patient that he is attending; and this is as it should be.

But these classical symptoms do not always occur in eases where there is rupture of the uterus, and then it is that mistakes are made in diagnosis, not from want of care on the part of the doctor, but from a too graphic and absolute a presentation of the accident on the part of the text-book.

The symptoms of rupture of the uterus are not always definite, as in the classical book illustration, and the term "silent rupture" has been used to denote the cases

(a) "Liverpool Medico-Chirurgical Journal," January, 1909.

of rupture of the uterus which occur without severe symptoms. Many such cases have been reported, where the doctor in attendance has not suspected the accident, and where the patient has died from septic infection or hæmorrhage, and the rupture of the uterus has only been discovered at the autopsy.

Such a case was reported by Dr. Barber, at the North of England Obstetrical and Gynæcological

Society, in 1904.

A woman was admitted to the Jessop Hospital. She had been delivered that day by version, after forceps had failed. She was said to have a laceration of the vagina. The House Surgeon reported to Dr. Barber that there was apparently nothing urgent about the case. She was 32 years of age, obese, two previous labours had terminated normally. The history was of onset of labour on November 1st, rupture of membranes November 2nd, and delivery on November 4th. She had no anxious expression, no restlessness, and did not complain of pain. The temperature 102° F. pulse 126. The abdomen moved with respiration, and was flaccid. The fundus uteri could be felt above the pubes; it was firmly contracted and somewhat tender, but not unduly so. Vaginal examination was difficult, but the cervix felt ragged and a tag depended from it. The urine contained a little blood at first, but none later. The patient remained comfortable all day, but pneumonia developed in the evening. Next morning the patient expressed herself as being very comfortable, but suddenly, a little time after an evacuation of the bowels, she became very ill and died in a few minutes, and without exhibiting any of the classical signs of internal hæmorrhage. Autopsy on the same evening: Abdomen enormously distended by gas in intestines and stomach; no signs of peritonitis; peritoneal cavity contained much free recent blood, and there was some in the broad ligaments, chiefly on the right side. There was rupture of the uterus, limited mainly to the lower uterine segment, and involving the peritoneum. The rent was posterior, and ran obliquely upwards from right to left. Bandl's ring was very conspicuous. Dr. Barber invited opinions as to what sign or group of signs could be taken to indicate the serious condition.

In considering the case, I should with some diffidence suggest that the long labour in a multipara, the delivery by version after the failure of forceps, the laceration, the temperature and pulse, would quite justify an abdominal operation, although I know that it is easy to be wise after the event.

In the last few years I have seen four cases of rupture of the uterus. All of these have been very similar in the position of the rupture and in its extent. The rupture in each case was L-shaped, and occupied the lower part of the uterus. The transverse tear ran across the cervix and sometimes extended to the vagina; and the perpendicular portion of the tear ran up the side of the uterus, in one case tearing through the uterine artery, causing so severe a hæmorrhage that the patient died. In all the cases the tear was so bruised and ragged that it seemed to me absolutely impossible to sew up the tear. In three of the cases the patients were taken into the Royal Infirmary as soon as possible after the occurrence of the rupture. In each of these cases the child had been delivered per vias naturales before the patient came into hospital. Each of these had presented the well-known symptoms, and in each had the condition been correctly diagnosed at once before her admission to the infirmary. treatment adopted in each case was the same. abdomen was opened and the entire uterus removed. Two of the cases recovered; one died. In the case that died the uterine artery on the right side had been ruptured, and the patient had almost bled to death before she arrived in the hospital; but the operation was performed to give her a chance of life, but failed. She died about twenty minutes after the completion of the operation-that was, about four hours after the accident.

The case to which I wish to draw special attention was unlike the rest, and because of this I mean to relate it more in detail. In the first place, the accident occurred without presenting the usual alarming symptoms, and it was not until 48 hours after the

labour that the accident was discovered, and yet she was attended by a careful midwifery expert, and the reason that the accident was then discovered was owing to the occurrence of intestinal obstruction.

Mrs. T., æt. 35, four children, had always had very rapid labours. On Saturday she was taken in labour, and sent for Dr. E. T. Davies, who had always attended her in her confinements, but who had never been able to arrive before the baby had been born, owing to the rapidity of her labours. On this occasion the messenger arrived at Dr. Davies' house about 6.30 a.m. Knowing the need for haste, Dr. Davies left on his bicycle and pedalled off to the patient, about 21 miles away. When he arrived he found, as usual, that the child had been born, the labour only having lasted about half an hour, but he discovered on examination that there was a second child in the uterus which was in a transverse position. He now found himself in a rather awkward position, because in his hurry to be in time he had not taken any chloroform with him. He therefore was compelled to turn without an anæsthetic. This he did, and delivered the child and placenta. The patient stood it well, but vomited soon after, and continued to vomit off and on all day.

The next day the patient was very sick, and there was considerable distension of the abdomen, more

especially in the upper part.

On the Monday, about 48 hours after the confinement, Dr. Davies asked me to see her, as she was still vomiting, and she had not passed any flatus since the confinement. The distension of the abdomen, too, had increased; the pulse 161, and the temperature 99.50 The patient was rathed excited, and looked anxious and ill, but talked quite freely and rationally.

On examining the abdomen, it presented a most peculiar appearance and shape. The lower part of the abdomen up to the level of the umbilicus was comparatively flat, and quite dull on percussion; above the umbilicus there was enormous distension, and the percussion note was tympanitic. The intestines seemed to lie almost together above the umbilicus. This was so marked that it looked as if the abdominal cavity were divided into two compartments by a semi-circular line drawn from each anterior superior spine to a point about one inch above the umbilicus. The abdomen was very tender, and examination was difficult. abdomen moved very little on respiration.

On making an examination per vaginam, a laceration could be felt in the posterior vaginal fornix, and a

knuckle of bowel was felt in the vagina.

The patient was removed to the Royal Infirmary, and the abdomen was opened in the mid-line. There was much fluid blood in the abdomen, with some clots. The uterus was pulled up to the abdominal wound, and it was seen that there was a ragged tear of the uterus, and protruding into the vagina was a loop of intestine which had become adherent to the sides of the tear. The intestine was freed and washed. The uterus was then removed entire, the vagina closed, and the patient returned to bed. No drain was used. The patient recovered well.

The tear in the uterus was L-shaped, the transverse portion of the L running across the posterior surface of the lower uterine segment about one inch above the vaginal cervix. The upright portion of the L ran upwards along the right side of the uterus, and extended for about three and a-half inches along the course of the uterine artery, but did not tear it. From the left side of the transverse portion of the L a tear ran downwards into the posterior wall of the vagina for about two inches.

Rupture of the uterus is one of the most serious accidents that can happen in labour, and it is still a very fatal accident. It is rather difficult to know what the mortality of the accident is at the present time, but it must be considerable, although it has altered in the last ten years enormously for the better. Much still depends on the site of the rupture, and also upon the promptitude of the doctor, but still more, perhans on the situation of the patient, and whether the accident occurs in hospital or in private practice. It is interesting to recall the figures given by Spiegel-berg of the mortality of rupture of the uterus. He

says that 95 per cent. of the cases of rupture of the uterus die.

Of course this estimate of the mortality was made years ago, before the improvements in the technique of abdominal operations came into vogue, and at a time when abdominal operations were not resorted to except as a dernier resort.

Now, I suppose any case of rupture of the uterus would be at once treated by abdominal operation, as this holds out the best prospect of life to the patient.

Schultze gave statistics of 193 cases collected about 1906. Complete rupture without treatment, 20.2 per cent. recovered; complete rupture treated with drainage only, 36 per cent. recovered; complete rupture treated

by laparotomy, 44.7 per cent. recovered.

Ivanoff (Annales de Gynécol. et d'Obstét., Aug., Sept., Oct., 1904) analyses 124 cases collected between 1877 and 1901; 80 cases occurred at Moscow Maternity. He gives the frequency of rupture 1 in 1,482 cases. Koblanck gives 1 in 462 cases. In the 124 cases the mortality was 81.75 per cent. All these were treated by gauze plugging and abdominal bandage. Of 58 cases of complete rupture, 7 recovered, giving a mortality of 87.75 per cent. Of 43 incomplete, 16 recovered; mortality, 61.18 per cent.

Ivanoff believes the fatal issue can only be prevented by operation. Of cases treated by abdominal section there were 60 per cent. recoveries, against 27 per cent. by expectant method. Ivanoff says all the so-called pathological modifications of elastic tissue of uterus as described by some authors are really physiological. He says the treatment of every rupture of the uterus during labour should be by operation, for by this means alone can the bleeding be arrested, and the region of the wound and the peritoneal cavity thoroughly cleansed.

The causes of rupture of the uterus are various, but they may be divided into two classes—traumatic and spontaneous. Milne Murray (Journ. Obstet. and pontaneous. Milne Murray (Journ. Obstet. and ynacol. British Empire, Vol. I.) divides them as follows :-

Traumatic-

Direct mechanical violence-

Forcible introduction of hand into Internal Unskilful performance of internal Traumatism. version. Improper use of forceps.

It need hardly be said such cases should not occur.

External External violence, blows, falls, etc. Traumatism.

Spontaneous. In cases of spontaneous rupture we assume that the immediately determining cause is the contraction of the uterus. Predisposing causes are various. The majority of cases are associated with some condition arising out of abnormality of either of the two factors of labour, passage or passenger.

Given any condition which interferes with or delays the dilatation of the os, the lower uterine segment becomes thinned out, while the muscular tissue of the upper segment gathers itself together into a sort of cap on the upper pole of the uterine mass. The strain on the thinned-out lower segment increases until it gives way. A tear so produced will tend to run across the long uterine axis, though the general direction of the tear may be altered by the splitting produced by the escape of the uterine contents. the developed tear may run obliquely or directly upwards.

If, on the other hand, the thinning-out of the lower segment is associated with contracted pelvis, the position of the rupture may be determined by the grinding of some portion of the thinning segment between the fœtal head and some bony ridge. A contused area may thus be formed in which the rupture may begin, in a transverse direction at first, and end vertically or obliquely. Or it may be that the point of rupture may be determined by an excessive thinning-out of the uterus over some prominent point in a mal-presenta-tion, such as a chin in a face case or occiput or shoulder in a transverse. Milne Murray further says: spontaneous rupture may occur, however, in certain cases without any process such as described by Bandl. There

may be no abnormal obstruction to the escape of contents.

 Interstitial pregnancy.
 Abnormal conditions—uterus bicornis, myomatous uterus, previous Cæsarean section.

3. Small number of cases where rupture occurred at beginning of labour, no abnormality found in uterus. Rupture of the uterus is in all probability a much

more frequent accident than is generally supposed; and seeing that autopsies are seldom made in private practice, it is not unlikely that many of the cases of mysterious death occurring three or four days after labour are in all probability due to unsuspected rupture of the uterus; also some cases doubtless recover.

I remember, many years ago, seeing a case of rupture of the uterus in a young unmarried girl. There was no doubt about the rupture, as the fœtus had escaped into the abdomen, but it had been delivered per vias naturales when I saw her. I advised operation, but this was refused. For two days she seemed likely to recover, but on the third she got up to pass water, and was suddenly seized with severe abdominal pain and died in a few hours. The patient was under the most unfavourable surroundings and amongst very obstinate people. There was no skilled nurse to attend to her; if she had had any proper attention it is possible that she might have recovered even without operation

This is the only case that I have seen of undoubted rupture of the uterus that has had no operative treatment; but there are statistics of the results of rupture of the uterus treated expectantly, and the results are very bad indeed—about 90 per cent. mortality. There are those who still advocate plugging and draining the tear, as being the safest treatment of complete rupture of the uterus. Amongst these are H. R. Spencer, who read a paper before the Obstetrical Society of London (Obstet. Trans., XLII.), and the general opinion in the discussion that followed favoured his views; also in the Journal of Obstetrics and Gynacology of the British Empire, July, 1908, Dr. Munro Kerr, in an elaborate paper on "Rupture of the Uterus," is inclined to side with Spencer; but in the last few years there is no doubt that opinion is gradually forming more and more in favour of abdominal operation for the treatment of complete rupture of the uterus.

Personally, I feel sure that where there is undoubted complete rupture of the uterus there is only one course to pursue, and that is to operate at once—open the abdomen, and deal with the condition found. In all probability the best course will be to remove the uterus; it must be very exceptional to find a tear that can be satisfactorily sewn up, although this has occurred. But even if the tear is sewn up there are considerable risks that have to be run in adopting this method of treatment. In the first place, there is always the danger of sepsis. In these cases there has in all likelihood been a prolonged labour, with manual or instrumental interference, and possible infection of parts before the operation is undertaken. Secondly, if the suturing of the tear has not been perfect, there may be a leak of the lochial discharge into the peritoneal cavity during the puerperal period. Thirdly, if the operation has been successful, the scar in the uterus will be a weak place, and there may be a rupture at a future confinement. So that in all probability the safest measure in a case of rupture of the uterus is to remove the uterus; and it is safer to remove it by the abdomen than by the vagina, because there will be much blood in the peritoneum that will require 10-moval, and the bleeding vessels are more easily and rapidly tied by the abdomen. As Nelson once marked, "the boldest measures are oft the safest."

# OUGHT TEA, COFFEE AND CHOCOLATE TO BE FORBIDDEN IN URICÆMIA.

By PROF. ALFRED MARTINET, M.D., Of the Faculty of Medicine of Paris

SPECIALLY REPORTED FOR THIS JOURNAL.

In certain diseases and constitutional states excessive quantities of uric acid are excreted; even the blood, according to Garrod, contains an excess

thereof. It is met with in excess in acute diseases, such as pneumonia and hepatic cirrhosis, especially the atrophic form, when it forms a copious deposit in the urine. The facts are familiar to everyone, but the interpretation to be placed thereupon is still far from clear.

Considerable progress has been made in the study of uric acid during the last few years. It has been shown that the greater part, if not the whole of it, is derived from the nucleins (nucleo-albumens and nucleo-proteins) contained in the cell nuclei, and in the purin bases, such as xanthine, hypoxanthine,

guanine, adenine, &c.

In opposition to the generally-received view, however, it is not to be regarded as a product of incomplete oxidation of albuminoid substancesi.e., an intermediate product between these and urea, and there is no relationship between urea and uric acid, since repeated dietetic observations have amply demonstrated that the nitrogenous excretion can be varied at will by a purin-free, but more or less nitrogenous, diet, the proportion of urinary purins remaining the same.

As a matter of fact, uric acid and the xanthein derivatives (xanthine and hypoxanthine), which are found associated and are described under the generic term, xantho-uric compounds, are derived from the disintegration of the cell-nuclei (endogenous); from the disintegration of the alimentary

nucleins or purin bodies (exogenous).

Repeated experiments have shown that in the normal individual a purin-free diet determines an invariable minimum of endogenous uric and xantho-uric excretion. This endogenous minimum appears to amount to from 0.40 to 0.50 gramme for the total purins, and from 0.30 to 0.35 for uric acid alone. These proportions may rise to a high level in certain pathological states (pyrexia, pneumonia, leucæmia, pernicious anæmia, &c.). As for the exogenous xantho-purins, their proportion varies according to the richness of the diet in these bodies. This comprises about all we know concerning the intra-organic formation of the xantho-uric compounds. Their pathological rôle still remains in great part to be worked out.

The interpretation to be placed upon the pathological phenomena in which uric acid appears to play an important part-attacks of gout, urinary lithiasis, articular pain, migraine, etc.—cannot be inferred from a comparison between the proportion of purins ingested and that of the xantho-uric bodies excreted. As a matter of fact (1), many persons placed on a dietary comparatively rich in purins never suffer from uricæmic accidents; not anyone can become gouty. (2) In certain pathological states, such as pneumonia after the crisis, and in leucæmia, there may be marked hyperuricæmia and hyperpurinia without this surcharge of the blood and urine, in respect of xantho-uric bodies giving rise to any of the uricæmic disturbances popularly

ascribed to the uricæmic state.

It will be seen, therefore, that the pathogenic problem is of a very complicated nature, and for a uræcemic accident to occur three factors appear to be necessary, and possibly suffcient-viz.: (1) A certain degree of hyperuricæmia; (2) a certain degree of impermeability of the kidney in respect of the xantho-uric bodies; and (3) a peculiar state of the xantho-uric bodies that renders them more prone to undergo precipitation within the tissues. We know that hyperuricæmia has been found to

exist in the blood of the gouty at a certain stage of the disease. Garrod, indeed, found as much as 0.01 gm. of uric acid per cubic centimetre of the blood, whereas in healthy subjects, at most, a trace can be discovered. This proportion seems quite inadequate per se to determine uricæmic accidents. Although in many gouty subjects there is unquestionably more or less renal impermeability, the influence of this factor is open to question. It would seem that, just as in diabetics in respect of carbohydrates, and in certain renal patients towards salt, gouty and uricæmic subjects, or some of them, have a limit of tolerance for purin-containing foods.

It has long been an article of belief that the quantity of uric acid in the blood undergoes variations in deference to circumstances still ill-understood. Recent researches have verified this assumption, and have also thrown light on the conditions that govern the solubility of uric acid. For instance, it has been shown that thyminic acid, a constant product of the breaking-down of nucleinic acid, and therefore of the nucleins, dissolves more than its own weight of uric acid at a temperature of 37° C., forming a stable compound which is with difficulty precipitated by acids. Nucleinic acid possesses very similar properties, so that uric acid derived from organic nucleoalbumens is normally accompanied by its natural solvent.

Moreover, many causes, still imperfectly known, may render uric acid more or less precipitable, whether, as suggested above, because it forms peculiarly soluble and barely precipitable compounds, or because it is oxidised and undergoes transformations which have the same effect, or, again, because, on the contrary, the presence in the blood of certain substances, such as tarmin, and sundry mineral salts, facilitate its precipitation.

It is unnecessary to insist on the importance of the last-named pathogenic condition, which possibly

overweighs all other factors.

The view that ceteris paribus, and according to the diet, uric acid is, or is not, soluble, at any rate, to any great extent, by hydrochloric acid, has been very cleary shown by Fauvel, who demonstrated that on a milk or vegetarian diet, free from purins, uric acid is not precipitable by hydrochloric acid, whereas on a meat diet it is so.

It is, however, impossible to draw a satisfactory, comprehensive explanation from these data. If we limit ourselves to what is known of the symbiosis—thyminic acid and uric acid—we might suppose that only the alimentary purins which do not form part of any complete nucleinic compound, and are, therefore, not accompanied by thyminic acid, are capable of yielding uric acid precipitable by hydrochloric acid.

Clinically, we meet with a certain number of subjects who almost invariably pass urine that precipitates merely on cooling, leaving a more or less copious deposit of a red colour, resembling brickdust. This sediment is composed principally of

uric acid and its derivatives.

Independently of patients suffering from acute pyrexial disease, pernicious anæmia, leucæmia, &c., in whom uric acid is always present in excess in the urine, this symptom is met with in persons who habitually consume large quantities of food rich in purin bodies: meat, fish, the legumens, chocolate, tea and coffee. We may endeavour to explain this by assuming the presence in the blood of a fairly large quantity of readily-precipitable xantho-uric products, and, if so, what conclusion is to be drawn from the organic point of view? It may not improbably be due to the presence in the blood of xantho-uric compounds of the same kind as those found in the urine, that is to say, in a state of unstable solubility, and therefore easily precipitated, and pro tanto injurious. This would suggest the desirability of trying, either for curative or

preventive purposes, to keep down the organic proportion to a minimum by suitable dieting, the only really and certainly efficacious means at our

disposal to obtain this result.

Be it remarked in passing that this hyperpurinia is, after all, a defensive reaction, an attempt to get rid of injurious bodies, and it may for a long time fail to give rise to any appreciable disturbance, the latter being dependent on the subject's limit of tolerance. It is easy to imagine, on the other hand—a fact that is often witnessed in gout—that urine poor in uric acid, such acid not being very precipitable, may be associated with an injurious degree of hyperuricæmia. From the pathogenic point of view, the most important is not the uric acid that is found in the vase, but, on the contrary, the uric acid that is left elsewhere. Nevertheless, habitual hyperpurinia is presumptive evidence of great value as indicating threatening hyperuricæmia, of xantho-uric super-saturation of the blood, with all its possible consequences in the event of precipitation under the influence of some accidental cause-chill, over-work, over-feeding, alcoholic excess, &c.

Our duty in such cases is, therefore, to suppress, or, at any rate, to restrict, the intake of foods containing nucleins and purins. Foremost among these are tea, coffee, cocoa, alkaloidal infusions or solutions, the latter being almost pure purins; 100 grammes of chocolate contains about 1 gm. 50 of theobromine; 100 grammes of coffee about 1 gm. 50 of caffeine; 100 grammes of tea 2 gm. 50 of theine and adenine. These purins are methyl-xanthins, the composition of which closely approximates that of uric acid and the xantho-uric bodies, thus justifying Haig's dictum that "coffee is really uric acid." It is therefore usual and rational to absolutely forbid the use of alkaloidal purinic drinks in the subjects of uricæmia.

Yet, before arriving at a definite conclusion, the question deserves to be thoroughly investigated. In a series of carefully carried-out dieteto-urologic observations, Fauvel found that with coffee and chocolate a seventh part of the theobromine, and a third of the caffeine, re-appeared in the urine in the form of purins, but these methyl-xanthins did not increase the proportion of uric acid, and the latter was not precipitated by hydrochloric acid. According to this same author, if theobromine or caffeine be added to urine in vitro, the uric acid of which is readily precipitated by hydrochloric acid, there is a well-marked decrease in the amount of acid precipitated.

It will be perceived that another factor comes into play here—vis., that very important factor of the variable solubility of uric acid compounds, and it may be asserted, indeed, that although tea, coffee and chocolate increase the proportion of xantho-uric compounds in the urine, and probably also in the blood, they also enhance its solubility.

Fauvel's experiments, however, do not warrant any definite conclusions:—(1) Because they only bore on a single subject whose renal permeability and purin-metabolism were normal; (2) because the experiment only lasted five days for chocolate, two days for coffee, and in respect of elimination, the observation only bore on the trial days, and not on the following days; (3) because it tells us nothing about the destiny of six-sevenths of the theobromine and two-thirds of the caffeine which were not discovered in the urine, and it is just this fraction that is of most importance. Is it eliminated daily in some form that eludes our present methods of analysis? Is it transformed and destroyed in the organism? Does it, on the contrary, accumulate

there, and subsequently provide material for the xantho-uric excretion? This we do not know.

We must certainly take Fauvel's researches into account, but it would be premature, and even

dangerous to accept them as a guide.

We must look to clinical experience to decide our line of conduct, and clinically we daily meet with subjects who suffer from various arthritic manifestations, the determining cause of which is clearly the abuse of tea, coffee and chocolate; in these subjects, indeed, simply withdrawing tea, coffee and chocolate causes these manifestations to disappear, apart from any other change of regimen. Among numerous observations, we may mention one bearing on a woman, æt. 20, who daily consumed large quantities of tea, and suffered from more or less chronic rheumatoid, articular pain, the right kidney being palpable and tender, and the urine being muddy, containing 1 gm.o2 of xantho-uric bodies. In this case complete withdrawal of tea, without any other change in her habits of life, brought about the subsidence of the troubles within three weeks, and the proportion of xantho-uric bodies fell to o gm.69. Conversely, in a man of 63, previously free from any rheumatic tendency, we have witnessed the supervention of very refractory rheumatoid pains after taking large quantities of chocolate for eighteen months, and medical literature teems with similar instances.

In practice we must, for the time being, adopt

the following conclusions:—

1. Alkaloidal beverages, especially tea, coffee and chocolate, should be forbidden for uricæmic subjects, especially those whose urine spontaneously precipitates uric acid.

2. Nevertheless, the action of coffee and chocolate appears to be less injurious to the organism than that of meat and the legumens, the latter appearing to predominate, for although uricæmic manifestations are specially frequent in meat-eating races or tea drinkers (Anglo-Saxons), it seems to be rather rare in people who are vegetarians, though they drink tea and coffee (Japanese, Hindus, Arabs, etc.).

In short, tea, coffee and chocolate may be allowed in moderation when the food is principally vegetarian and hypopurinic, but they should be strictly forbidden when the diet comprises much meat, which is the case in most instances of "excretors

of uric acid."

# DISINFECTION OF HOUSES IN INDIA, (a)

BY DR. SORAB C. HORMUSJEE, Assistant to the Health Officer, Bombay Municipality.

In the course of his paper Dr. Sorab said his main object was to give an outline of the methods of disinfection in vogue in Bombay City, and which of them are most effective, convenient, and economical. The Indian Plague Commission, he said, appointed in the year 1898, after carrying out certain experiments, came to the conclusion that an acid solution of perchloride of mercury of the strength of 1 in 1,000 was a chemical disinfectant that was most likely to render efficient service in plague-infected houses. But within the last two years the researches of the Second Plague Commission which were carried out at the Bombay Bacteriological Laboratory, and which have con-clusively brought to light the fact that the plague is communicated to man from rats by means of rat-fleas, have brought about a considerable alteration in the method of dealing with plague-infected houses.

This important discovery—viz., that plague is communicated from rats to rats and from rats to man by means of the rat-flea-suggested the use of a pulicide, because we are now in a position to know that plague bacilli exist in nature either in the body of a plague-sick animal (chiefly the rat) or in the stomach of a rat-flea which has fed on such an animal. Perchloride of mercury, although it is a powerful bactericide, is not an insecticide. In the light of these recent researches, therefore, regarding the manner in which plague is com-municated, perchloride of mercury is useless as a disinfectant for plague-infected houses. Since August, 1906, Dr. Turner, Executive Health Officer, Bombay, introduced the use of pesterine as a disinfectant for houses infected with plague. The word "pesterine" is merely used for convenience of ex-pression. This substance is crude petroleum (fuel oil), and is undoubtedly a powerful insecticide, as it instantly kills all fleas, bugs, and other insects that come in contact with it. The Director of the Bombay Bacteriological Laboratory has recently suggested the use of kerosene oil emulsion for the disinfection of plague-infected houses. This emulsion is prepared by dissolving 3 parts of Sunlight soap in 15 parts of water by boiling. Warmed kerosene oil is then to be added to this soap solution gradually up to 100 parts. Finally the oil and soap water should be mixed together by shaking or stirring the mixture. The same officer also recommends the use of hydrocarbon emulsion, which is prepared in a similar manner to kerosene oil emulsion, except that the hydrocarbon is not warmed. PLAGUE BACILLI.

Although as a rule the plague bacilli exist in the stomach of a rat-flea which has fed on an infected animal, it is by no means certain that they do not exist in other substances. For instance, the excreta of sick animals or man also contain them. The second Plague Commission, in one of their reports, state that the plague bacilli, when present in such excreta, are as a rule rendered quickly harmless either by desiccation or by the development and multiplication of saprophytic bacteria, which are inimical to the existence of plague bacilli. The fact, however, of the existence of these bacilli in places other than the stomach of the flea, necessitates the use of some disinfecting agent which has both pulicidal as well as bactericidal powers. end in view, our Municipal Analyst, Dr. Ghadially, suggested, in August, 1907, the use of kerosene oil emulsion mixed with cyanide of mercury. The latter chemical is as powerful a germicide as mercuric chloride, and has the advantage of not being precipitated by albumen, gelatin, mucin, and organic matters, and can therefore be usefully employed on mud floors smeared with cowdung. Ghadially suggests that cyanide of mercury added to the kerosene oil emulsion in sufficient quantity to make its strength 1 in 50 would be an ideal disinfectant for plague-infected houses.

It is perfectly reasonable to suppose that such a disinfectant possessing the combined properties of an insecticide as well as a germicide would not only be valuable in cases of plague, but also in cholera and typhoid fever cases, when we bear in mind the important part which flies play in the propagation

of the two latter diseases.

Dr. Sorab went on to point out that, owing to the nature of the bacilli in the body of a plague-sick animal such as the rat, or in the stomach of a rat-flea which has fed on such an animal, the most successful disinfectant would be such as is capable of destroying both rats

<sup>(</sup>a) Abstract of Paper read before the Indian Medical Congress at Bombay, February, 1909.

and their fleas. The fact that rats and fleas were generally to be found in situations inaccessible to the application of the disinfectants mentioned above materially handicaps the use of these substances. It therefore stood to reason that a gaseous disinfectant, alike poisonous to rats and fleas, and capable of penetrating into the inaccessible places frequented by these creatures, was the only one which offers some hope of success in combating the disease. A discussion of Clayton gas sulphur fumigation and formaldehyde gas and other disinfectants closed the paper.

# SPECIAL APPEAL.

## THE EARLY RECOGNITION OF UTERINE CANCER. (q)

AN APPEAL TO MEDICAL PRACTITIONERS TO PROMOTE THE EARLIER RECOGNITION OF ULTERINE CANCER.

THE attention of all Medical Practitioners is directed to the necessity of emphasising the curability by operation of uterine cancer in its early stages.

The adoption of a more extensive operation by the abdominal route has made it possible to deal successfully with cases hitherto regarded as inoperable, and to remove more of the pelvic cellular tissue as well as a portion of the vaginal walls; it is in these situations that recurrence is prone to develop.

Many patients now present themselves for examination and treatment when the disease is considerably advanced, and it is hoped that by a wide-spread and accurate knowledge of the early signs and symptoms

the number of such patients will gradually diminish. Special attention is directed to the following:—

- 1. Cancer of the uterus is at first a local disease,
- 2. Cancer of the uterus is often a curable disease.
- 3. Operation is the only satisfactory method of treatment.
- 4. The earlier the disease is recognised the more hopeful are the prospects of treatment.
- 5. The risk of operation in early cases is slight, and the chance of permanent cure is good.
- 6. The recognition of early cancer is not usually difficult, and the disease should not be overlooked by the medical attendant.
- A medical practitioner who fails to make a physical examination of the patient exhibiting any of the symptoms of uterine cancer incurs grave responsibility.
- 8. Treatment of symptoms without a physical examination is unjustifiable.
- Early cancerous ulcers should not be treated with caustic; their appearance becomes masked, and valuable time is lost.
- 10. It is an error to wait and observe in order to arrive at a diagnosis.
- II In doubtful cases a diagnosis must and can be made in a few days.
- 12. To examine, to diagnose, and then to treat, should be the rule in all cases.

Symptomatology.

Uterine cancer is at first a painless disease which does not affect the general nutrition.

The early symptoms of cancer are:—Irregular bleeding of any description, even if there be only traces; bleeding post coitum; and watery, blood-tinged discharge. There may be no loss of strength or wasting, nor any condition to alarm the patient. Pain, wasting, profuse bleeding, and foul discharge, indicate advanced disease

As the majority of cases occur between the fortieth and fiftieth year, the symptoms are too often regarded by the patient as due to "change of life." The medical attendant should not accept this assumption until he is satisfied that cancer does not exist.

(a) This appeal has been forwarded to us by the Editor of the Bri:. Med. Journ., in which journal it will also appear on the 15th inst.

Bleeding, however slight, occurring after the menopause, should give rise to the suspicion that cancer is present.

Examination.

If a patient with any of the above symptoms comes for advice, a careful visual and bi-manual examination must be made before any treatment is recommended.

Should a patient refuse to be examined—and this is exceptional when the situation is explained the medical attendant should decline any further responsibility, and no treatment should be advised. The examination should be made, even if bleeding is present, as valuable time may be lost by postponement until the hæmorrhage has ceased.

It is most important to observe rigid aseptic pre-

cautions in all manipulations.

In the examination, the condition of the vaginal portion of the cervix and of the cervical canal should

be carefully noted.

In the early stages new growth may be found on the surface of the vaginal portion of the cervix, in the lining of the cervical canal, or in the substance of the cervix. Any prominence on the surface of the vaginal portion or any ulceration, i.e., a definite loss of substance, should at once arouse suspicion. A nodule or nodules, hard, inelastic, or irregular in outline, felt in the substance of the cervix, suggest the presence of cancer. If the whole cervix be affected, the relative hardness as compared with the soft elastic body is pronounced.

The detection of high-lying cervical cancers, and cancers of the body of the uterus, is only possible

after curettage or digital exploration.

The signs common to the early stages of cancer of the cervix uteri are :-

- (1) The definite occurrence of new growth on the surface of the vaginal portion of the cervix in the lining of the cervical canal, or in the substance of the cervix;
- (2) Friability;

(3) Bleeding on manipulation.
(1) The definite occurrence of new growth on the portio vaginalis or in the cervical canal cannot fail to arouse suspicion. When, however, thickening of one lip or a portion of one lip of the cervix exists, the nature of the growth is difficult to determine if the mucous covering be still intact. It is then necessary to remove a portion of the affected tissue and examine it under the microscope.

(2) Friability is a sign of the greatest importance, and may be tested by the finger nail, curette, uterine sound, or an ordinary long probe. Degrees of friability exist in early cases, depending upon the amount of interstitial tissue contained in the growth.

(3) The occurrence of free bleeding after the slightest manipulation is, when combined with friability, a valuable diagnostic aid.

Forms of Uterine Cancer.

Vaginal portion of the cervix.

(1) Infiltrating type.—In this type, one lip, or a portion thereof, or even the entire vaginal portion of the cervix, is infiltrated with cancerous growth. Ulceration occurs early from the surface inwards, or necrosis may begin in the centre, and opening on the surface, lead to the formation of a deep ulcer,

with undermined edges.

The growth is somewhat hard in consistence, but is still friable if tested with the

- probe, curette, or finger nail.
  (2) Papillomatous or polypoid type.—This includes the so-called cauliflower excrescence, and is characterised by the growth from the margin of the os externum of a rounded or flattened tumour, varying in size, which may or may not have a definite stalk. It has a papillary surface, bleeds readily, and is very friable. More rarely it resembles a bunch of soft papillomata. Portions of the growth, pale red or greyish yellow in colour, are easily detachable on examination.
- (3) Superficial flattened type.—This is characterised

by a flattened growth on the vaginal portion which tends to spread over its surface. It is prone to early ulceration and is frequently seen clinically as an ulcer. The lip or portion affected is thickened. The ulcer has a sharply defined, raised edge, indented at places, yellowish grey, finely granular surface, a moderate amount of loss of substance, and an infiltrated base. bleeds readily on touch and the amount of hæmorrhage is entirely out of proportion to the amount of injury inflicted. The finger-nail can detach small pieces from its

The circumstances which led to the preparation of

this appeal are briefly as follows:

At the annual meeting of the British Medical Association at Exeter in 1907, the Section of Obstetrics and Gynæcology adoped a resolution requesting the Council of the Association to appoint a committee to consider the best means of disseminating knowledge of the importance of the early recognition of uterine cancer. That committee presented a report which was considered and generally approved by the same Section at the annual meeting of the British Medical Association in Sheffield in 1908.

Cervical Canal.

- (1) Superficial type.—The inner surface of the cervical canal is lined by an irregular papillary growth which at first attacks the substance of the cervix superficially. As the growth increases portions of it may protrude through the external orifice of the cervical canal. When ulceration occurs the superficial portions of the cervical canal. tion of the growth is shed, with consequent hollowing out of the cervical canal, whilst the remainder of the periphery of the cervix is more or less thickened by infiltration. Where the external os uteri is narrow the process may be hidden, or patency of the os uteri may be produced by destruction of its margin, whilst in uteri where the os
- is already wide a crater-like cavity is formed.
  (2) Infiltrating type.—The cancerous infiltration proceeds from the mucous membrane deep into the tissues of the cervix, and thus the whole cervix becomes thickened and enlarged, or the enlargement and infiltration may be limited to one or more portions of the cervical walls. Necrosis may commence on the mucous surface, or in the centre of the infiltrated area and may lead to extensive destruction of the cervical tissues.

Probably the majority of cancer cases which are overlooked are examples of disease affecting the lining of the cervical canal or the tissues of the wall of the cervix.

Cancer beginning in the cervical canal is not difficult to detect where the os uteri is dilated as in many multiparæ. The finger passed into the cervical canal feels irregular elevations or nodules from which portions may be removed. Free hæmorrhage follows Difficulty arises where the os this manipulation. uteri is not dilated and the disease is hidden. A sound carefully passed into the cervical canal may give the impression of impinging on an irregular nodular surface, or friable tissue may be removed by the curette. Free hæmorrhage following such manifestations is a suspicious sign. Thickening and hardening of the cervix may be detected by a rectal examination which is most helpful in detecting cancerous nodules in the cervical walls, and should always be made in such cases.

Body of the Uterus. 1

If the vaginal portion of the cervix, the cervical canal and the cervical walls have been proved to be free from disease attention must be directed to the body of the uterus. The uterus may not be enlarged, although a cancerous growth exists in its interior.

Usually, however, there is some increase in size, which in advanced cases may be considerable.

Microscopical Investigation.

In doubtful cases, if there be a suspicious hard nodule, or erosion, or ulcer on the external os uteri, a piece including a boundary of healthy tissue should be excised.

The vulva and vagina having been thoroughly cleansed, the posterior vaginal wall should be retracted by means of a speculum, and the cervix pulled slightly downwards with a volsellum. A wedge-shaped piece, the size of a pea or bean including a margin of healthy tissue should be excised with a sharp knife.

The bleeding which follows this little operation should be stilled by the insertion of one or two sutures,

or by firm tamponade with a strip of gauze. An anæsthetic is not essential. The patient should be kept in bed for 24 hours.

The tissue removed should be transferred to a small stoppered bottle filled with absolute alcohol or methylated spirit, and forwarded without delay to an expert

in uterine pathology.

Where the cancer originates in the body of the uterus or in the cervical canal, it is frequently possible by using the curette, to obtain a sufficient amount of tissue for examination without the aid of anæsthetics. If this cannot be done, it may be necessary under an anæsthetic to curette the whole interior of the uterus and cervix, special attention being paid to the region of the tubal orifices (a). All fragments should be collected, including those which may have been washed The douche, if employed, should consist of sterilised water or a weak solution of corrosive sublimate (1 in 10,000), as carbolic acid and lysol interfere with the staining of the cells.

The fragments should be transferred to a stoppered bottle filled with absolute alcohol or methylated spirit. If the expert's report is favourable the patient will be reassured, if unfavourable immediate operation is imperative.

The Operation.

The question of operation is best decided by the operator, who may require to examine under anæsthesia.

- To Recapitulate.
  (1) Attend to all symptoms suspicious of cancer, and instruct the patient on their importance; Examine immediately all cases of bleeding or
- abnormal discharge;
  (3) Make a definite diagnosis and do not wait for
- the disease to develop;
  (4) Urge immediate operation if the diagnosis is
- established.

The practitioner who diagnoses cancer in an early stage, when operation offers a probability of cure, renders a service to his patient as great as that rendered by the operator.

An Appeal to Midwives and Nurses in order to PROMOTE THE EARLY RECOGNITION OF CANCER IN THE WOMB.

Cancer of the Womb is a very common and fatal disease in women, but it can be cured by operation when it is recognised early. A woman sometimes tells a nurse or midwife her ailments before she speaks to a doctor, and the nurse or midwife has then an opportunity of aiding our crusade against this terrible disease.

Cancer may occur at any age, and in a woman who looks quite well and who may have no pain, no wasting, no foul discharge and no profuse bleeding.

To wait for pain, wasting, foul discharge, or profuse bleeding is to throw away the chance of successful

treatment.

The early signs of Cancer of the Womb are-

- 1. Bleeding, which occurs after the change of life.
- 2. Bleeding after sexual intercourse, or after a vaginal douche.
- 3. Bleeding, slight or abundant, even in young

<sup>(</sup>s) Special care should be taken in using the curette. as the ancerous uterus is easily perforated.

women, if occurring between the usual monthly periods, and especially when accompanied by a bad-smelling or watery bloodtinged discharge.

4. Thin watery discharge occurring at any age. The nurse or midwife who is told by a patient that she has any of these symptoms should insist upon her seeing a medical practitioner in order that an examination may be made without delay. By doing so she will often help to save a valuable life, and will bring credit to herself and to her calling.

# **OPERATING THEATRES.**

GUY'S HOSPITAL.

LAMINECTOMY FOR PAINFUL STUMP.-Mr. R. P. ROWLANDS operated on a man, æt. 50, who had been admitted suffering from intolerable pain in the stump of the left arm, the result of an amputation performed elsewhere about five years ago for compound fracture. At various times since several operations had been performed for painful stump. At the first the upper end of the humerus had been removed from the glenoid For the second the patient came under Mr. Rowlands' care at Guy's Hospital, when the neuromata were removed from the ends of the median, the ulnar, and the musculo-spiral nerves. This was not followed by success in relieving the pain. At the next operation, about a year and a half ago, the anterior primary divisions of the fifth, sixth, seventh and eighth cervical nerves, and of the first dorsal nerve, were exsected before they joined to form the brachial plexus. In this manner it was hoped to cure the pain, but, unfortunately, only temporary relief was obtained. man was a night watchman, but lately has had to give up his employment. He stated that he got very little sleep. He has much aged in appearance, and his hair has turned almost white during the last four years. He had threatened suicide on several occasions, having tried a variety of drugs in vain. Mr. Rowlands sent the patient to see Dr Hertz, who is in charge of the electrical department, with the view of the employment of electrical treatment, but the latter recom-mended the removal of the posterior roots ganglia.

The patient was anæsthetised and placed on his right side, with a sand pillow under his head. A large flap was taken up and turned inwards and downwards; the flap comprised all the muscles down to the semi-spinalis colli. The deeper muscles were peeled off the laminæ and retracted to the left. The deeper cervical vessels were secured at this stage of the operation. The laminæ and articular and transverse processes on the left side of the fourth, fifth, sixth and seventh cervical vertebræ and first dorsal vertebra were thoroughly exposed, and the laminæ were divided with Horsley's forceps close to the spinous and articular processes, portions of which were also removed. In this way the dura mater and the nerves were brought into view. The posterior root ganglia of the fifth, sixth, seventh and eighth cervical nerves, and first dorsal nerve, were drawn inwards, isolated, and removed. A good deal of bleeding occurred from the deep muscular vessels and the deep plexus of veins; a solution of adrenalin was poured into the wound with some advantage. This sent up the blood pressure and improved the pulse at a critical stage. (Dr. C. D. Edwards, who was making blood-pressure observations at the time, noticed that a great fall in the blood-pressure occurred after the escape of a considerable amount of cerebro-spinal fluid, which happened when one of the posterior root ganglia was being isolated. The operation lasted about an hour, and, owing to the great depth of the spinal canal in this patient (he was a big and rather stout man), the exposure of the ganglia presented many difficulties. At one time the pulse reached 170 per minute. A small gauze drain was placed in the wound, which was closed at all other

Mr. Rowlands pointed out that this severe operation seemed to be justified, for the following reason: The pain was so intolerable the man elected to run any risk in the hope of getting rid of it, and he had several times threatened to commit suicide. It was probable, Mr. Rowlands thought, that the cause of the pain was

an ascending neuritis following the original septic injury to the arm. This seemed to be confirmed by the entire failure of the several operations for painful stump. Granting this diagnosis to be correct, then the removal of the posterior roots ganglia should cure the pain, because the disease does not extend into the cord, which is itself insensitive. The experiments of Sherrington and others, pathological evidence, and the results of the removal of the Gasserian ganglion for trigeminal neuralgia, he said, seem to justify the The alternative diagnosis of functional neurosis had been well considered, but the man had been kept under observation in the hospital, and his insomnia proved to be genuine. It is, he remarked, unnecessary to remove more than half of each laminæ in such a case, and this moderation has the great advantage of not weakening the neck to anything like the same extent as complete removal of the selected laminæ and the spinous processes.

Ten days after the operation the stump is insensitive, but it is too early to say what the ultimate result of the operation will be. The shock soon reacted to treatment. The man had a great deal of headache for two or three days after the operation, due probably to loss of cerebro-spinal fluid, which continued to

drain away in small quantities.

# TRANSACTIONS OF SOCIETIES.

THE ROYAL SOCIETY OF MEDICINE.

CLINICAL SECTION.

MEETING HELD APRIL 30TH, 1909.

Dr. ARCHIBALD E. GARROD in the Chair.

FOURTEEN cases of Mongolian imbecility were exhibited.

Dr. G. A. SUTHERLAND showed three cases of this condition.

CASE I.-A male, æt.  $5\frac{3}{4}$ , an only child. The mother was 43 and the father 39 years of age at the time of his birth. There had been three miscarriages before patient's birth. He cut his first tooth at 12 months; learned to stand when 2 years old; walked and talked when 3 years old. He had never been cyanosed. The special physical characteristics were: A small head, small palpebral fissure with the axis sloping inwards and downwards, depressed bridge of the nose and epicanthus, the openings of the nares directed upwards, the mouth wide open, the tongue large, with some transverse fissuring, horizontal nystagmus and head shaking. The little finger and thumb were shortened, with slight curving of the former. There was no cardiac disease. Nasal obstruction had been pronounced until operation for adenoids had been done. The boy was very imitative, active, and required constant supervision. His habits were clean. Mental development was progressing, but was still very backward.

CASE 2.—Female, æt. 6. One other child in the family, æt. 12, is healthy. The mother was 40 and the father 39 years of age at the time of the patient's birth. The patient cut her first tooth at 13 months, began to stand and talk at the age of 3 years, and to walk at 3½ years. The abdomen was prominent, with an umbilical hernia. Head markedly brachycephalic and flattened antero-posteriorly; palpebral fissure small and sloping; nose not depressed; no epicanthus or nystagmus; tongue large; thumbs rather shortened; slight muscular hypotonus; no cardiac disease. She was active, imitative, and fond of music, and required constant supervision. Mental development was pro-

Case 3.—Male, æt. 4. One brother, æt. 18, and a sister, æt. 8, are both healthy. The patient could say simple words, and learned to walk at the age of  $2\frac{1}{2}$ years. He presented the typical features of Mongolian imbecility. The left hand showed also webbing of the third, fourth, and fifth digits. He was very fond of music, imitative and active. There was no evidence

of cardiac disease.

Dr. F. J. POYNTON showed four cases:-

CASE 1.—Female, æt. 4, a characteristic Mongol, was one of a considerable family, and was born when the mother was 40 years of age. There is a younger child who is healthy. The patient was brought to Great Ormond Street Hospital when aged 6 months, and since then had been treated with small repeated doses of thyroid. She talked when aged 2 years and 10 months, was passionate, fairly clean, and could say a few words, such as "pappa," "mamma," "more." Fond of musical sounds.

CASE 2.—Male, æt. 9, was the second child, the first and third children being normal. He had always been noticed to be backward. He took the bottle until set. 3, and for many months, instead of attempting to walk, and for many months, instead or attempting to walk, propelled himself about in tailor fashion, eventually walking between 3 and 4 years of age. He had been treated since September, 1908, with small doses of thyroid. The degree of intelligence was small. His aspect was of the usual type, and his manner characteristic was this ground the contraction. teristic of this group of cases. Since this treatment had been started friends and relations considered him "brighter," but it was difficult to discover any real improvement.

CASE 3.—Female, æt. 3, was the youngest of three children, being 7½ years younger than the next child. She was noticed to be "peculiar" at 3 months of age, and was unable to suck her bottle, but she cut her teeth at about the usual time. This case appeared to be of rather a milder type than some. She had been treated for over a year with thyroid, and during this time had made progress.

CASE 4.—Female, at. 4, had been treated since the age of 10 months with small continuous doses of thyroid. This characteristic Mongol was now beginning to talk, and was fairly clean. She did not appear to have made any real advance over other cases which had not had thyroid treatment.

Dr. FREDERICK LANGMEAD showed two cases.

CASE 1.-Male, aged 1 year and 7 months, was the only child of a young and healthy mother, æt. 26, who has not had any miscarriages. The facies was characteristic of the condition. Occipital development was more than usual in such cases. General growth was considerably delayed. The child sat up with difficulty, and could not properly support his head. Mentally he was cheerful and tractable, but had not made any attempt to speak beyond curious laryngeal noises. The little finger is not characteristically stunted nor incurved. Excluding an umbilical hernia and a prominent post-anal dimple, there were two associated malformations: (1) Congenital morbus cordis as evidenced by a loud systolic bruit, heard with greatest intensity at the inner end of the fourth left intercostal space, but also at the apex and along the left sternal margin; and (2) an accessory auricle on the right side. The cardiac condition caused some blueness at birth, and attacks of pallor and collapse during the first twelve months of life, but since then had not produced symptoms.

CASE 2.—Female, æt. 3, was the tenth of eleven children, three of whom died in early infancy. The youngest child was healthy. The aspect was children, three of whom died in early infancy. And youngest child was healthy. The aspect was characteristic of the condition, but the back of the head was not so flat as usual. There were grimacing and projection of the tongue, which was "granular" and projection of the tongue, which was granular from the enlargement of the papillæ and showed slight longitudinal fissuring. Growth was stunted, and development retarded. She made noises interpreted by the mother as "mum" and "dad." She was playful and mischievous, and showed her apprecia tion of music by moving her hands in time to a barrelorgan or piano. There was a congenital lesion of the heart, as shown by an increase of the cardiac dulness to the right and an evident but slight murmur in the pulmonary area. The heart malformat caused any symptoms or secondary signs, The heart malformation had not

Dr. LEONARD GUTHRIE showed two cases.

CASE 7.—A male, at. 5, in August, 1006 was admitted to the hospital for being dirty in his habits and bad-tempered. When examined he showed the usual Mongolian aspect, grimacing and gestures. He understood little that was said to him, and his speech was unintelligible except for a few words. He was extraordinarily imitative. After six months' stay in

the hospital he had considerably improved in intellect His habits were clean, and he was and manners. generally docile.

CASE 2.—A male, æt. 8, with signs of cretinism, who had improved under thyroid treatment. He was

first seen when 1½ years old.

Dr. MORLEY FLETCHER also showed three cases of Mongolian imbecility.

These cases were then discussed:
Dr. G. A. SUTHERLAND demonstrated the chief features of the condition, and said that the cause was still unknown. He did not think that any treatment, including that by thyroid did any good. Such patients were always lacking in vitality, and often died unexpectedly. Several died from 2 years onwards from tuberculosis.

Dr. POYNTON said that he had treated 12 cases for prolonged periods with thyroid, sometimes for over one year. He did not think that it had any specific action on the underlying constitutional deficiency. If this treatment were pressed, it was not well borne. Perhaps there were different grades of severity of the disease, some of which improved, whilst others did not. He had not seen more than two cases of asso-ciated congenital heart disease, and thought it inadvisable to operate upon the adenoids early.

Dr. LANGMEAD said that his first case was exceptional, in that he was the first-born of a young and healthy mother, æt. 26. Usually Mongolian imbeciles were born either at the end of large families or when the mother was getting towards the end of the child-bearing period. This was shown by his second case, where the child was the tenth and the mother 39 when it was born. Another point of interest shown by his first case was the associated malformations, i.e., a congenital heart lesion and accessory right auricle. second case was also the subject of congenital heart disease.

Dr. Morley Fletcher said that the characteristic flush on the cheeks did not occur until after the second year, and was preceded by a pallid, transparent skin. It was difficult to explain the blepharitis which was almost always present. He did not think that any deformity of the hand was characteristic. He had never seen any cases over puberty. Thyroid treatment had no effect except on the disposition.

Dr. Leonard Guthrie agreed that thyroid was useless in the ordinary cases. In his first case there were also signs of cretinism, and in such cases there were duced improvement. Both his cases were very imitative, but he thought that they always failed to profit

much by teaching.

Dr. SHUTTLEWORTH said that there was in the minds of the profession much confusion between Mongolism and cretinism. He was not so despondent as Dr. Guthrie about training, and could show several children, where the hands were being used with utility. They never became efficient workmen, but improved by imitation up to puberty, then came to a standstill, showing no power of originality. They were prone to tubercle, and usually died early, but lived longer in the better classes from among which Dr. Langdon the better classes, from among which Dr. Langdon Down had shown 14 cases, in ages ranging from 24 to 56. He had seen several cases of backward children who showed only a suggestion of Mongolism. With regard to the frequency of this condition, it constituted 5 per cent, of the defectives at the Royal Albert Asylum and 2.6 per cent. at Earlswood.

Mr. J. Jackson Clarke showed

SIX CASES OF CONGENITAL DISLOCATION OF THE HIP AFTER MANIPULATIVE OPERATION.

CASE 1.—Girl, æt. 6½ in August, 1903, when she was operated on for a right congenital dislocation, the diagnosis being confirmed by X-rays. When last seen. November, 1905, the result was a perfect restoration of the joint, the femoral head being in the acetabulum. The father wrote (February 27th, 1907): "She can

walk and run as well as any ordinary child."

Case 2.—Female, æt. 5½ when she was operated on for a left congenital dislocation (the diagnosis was confirmed by X-rays) on April 22nd, 1904. When last seen.

September, 1904, the joint appeared to be normal.

CASE 3.—Female, æt. 10 in May, 1904, when operated on for left congenital dislocation; diagnosis confirmed by X-rays. Owing to patient's age secondary changes

had occurred in the form of the bones, and after reduction a good deal of exercising was required to over-come stiffness. Eventually a true reduction with good function was obtained.

CASE 4.—Female, æt. 3 when operated on for right congenital dislocation; diagnosis confirmed by X-rays. A perfect result was obtained, the skiagram published in the British Medical Journal, 1905, ii, p. 784, showing an anatomical reduction.

Case 5.—Female, æt. 3 when operated on for a pro-nounced double dislocation, confirmed by X-rays. In

both joints a perfect anatomical result was obtained.

CASE 6.—Female, æt. 8 when operated on for a pronounced double dislocation (diagnosis confirmed by X-rays) in November, 1904. This patient, who was very delicate and had marked rickets, had been continuously under observation. One hip was anatomically and physiologically normal; the other was fimly lodged under the anterior superior iliac spine (anteverted) and had a good range of movement.

The above six cases were taken from the first consecutive and inclusive series of ten cases operated on from four-and-a-half to five-and-a-half years ago by the exhibitor. Of the remaining four one cannot be traced. She was shown before the Clinical Society as lately as April 28th, 1905, and she then walked well and the dislocated hip-joint that had been operated on, as seen in a skiagram shown at the meeting, was anatomically reduced. In short, the ten patients included in this series presented twelve congenital dis-locations. Of these nine are cured, one materially improved, and only two failed.

Mr. V. Warren Low also showed a case, in which

treatment had been very successful.

Mr. James Sherren showed a patient six years after

the performance of

OMENTOPEXY FOR ASCITES DUE TO CIRRHOSIS OF LIVER. Mrs. —, æt. 34, was admitted into the London Hospital in April, 1903. She had been confined three weeks before admission, and it had been noticed that her abdomen remained swollen. When seen about a week after her admission the abdomen was distended with fluid, the liver could just be felt below the costal marking and the spleen was markedly enlarged reachmargin, and the spleen was markedly enlarged, reaching nearly to the umbilicus.

At the operation on April 28th the abdomen was found to be filled with clear yellow fluid. The liver found to be filled with clear yellow fluid. The liver was firm and typical of the type of cirrhosis known as "alcoholic." There were a few adhesions of omentum to the enlarged spleen, which was firm; its capsule was thickened, and scattered over it were a few opaque-white patches. The parietal peritoneum was stripped from the posterior surfaces of both recti muscles and the omentum was stitched into the pockets thus made and between the edges of the muscles. A tube was inserted and the fluid drained for three weeks. The wound healed by first intention, and she left hospital free from

ascites and feeling well on May 27th.

She had been seen on several occasions since, and had remained free from symptoms. Two years after operation she bore a healthy child. The splenic enlargement had gradually diminished.

He had observed six other cases, but no permanent benefit had resulted in them. One had improved for

two years.

Mr. C. Gordon Watson said that several such cases had been operated upon at St. Bartholomew's Hospital, but that usually the result was a complete failure.
Dr. H. D. Rolleston said there was discrepancy

between statistics and personal experience. The difficulty lay in choosing suitable cases for operation before nutrition was impaired. His most successful case had lived one year and a month.

Dr. H. G. Turney showed a case of

TROPHŒDEMA FOLLOWING TRAUMA.

Male, at. 18. Six months ago he ran a nail into the inner border of his right foot and had not been able to work since. The slight injury soon healed, but ever since the accident the foot had been increased in

size. There had been no pain to speak of.

The condition was one of cedema of the right foot, which stopped abruptly at the ankle. The colour was normal; the skin dry and coarse, and the nails thickened. Movements were free and not painful. There was some general blunting of all forms of sensation (but particularly that of pain) not only over the foot but nearly up to the knee. The X-ray examination was negative. The coagulation-time of the blood was normal, and there were no varicose veins. There was no sugar or albumin in the urine. There was no sign of disease about the nervous system generally, except a well-marked vasomotor instability.
Dr. T. D. SAVILL and Dr. PHILIP GREEN showed a

SCLERODERMIA ASSOCIATED WITH ANGIONEUROTIC

GEDEMA.

Female, married, æt. 56. The skin of the hands, nose, forearms, and, to some extent, of the toes, was thickened and livid. There was no pitting on pressure. She could not use her hands to button her garments because of the mechanical difficulty of the mechanical diffi ments because of the mechanical difficulty of flexing and extending the joints. In the forearms the parts were becoming hidebound owing to the thickening of the skin and subcutaneous tissue. Over the left clavicle was an area of smooth, shiny, thinned skin, such as that left by morphea.

Her previous history was interesting.

bilious attacks, starting in the early thirties, about once a week. Alternating with these she had attacks of swelling on various parts of the surface of the body. Both the bilious attacks and the swellings ceased about two years ago, at the age of 54, when the hands first began to be persistently affected. The attacks of skin swellings had all the characters of angioneurotic œdema.

The family history was also interesting. Her mother died at the age of 54 of a sudden swelling of the face spreading to the throat, and causing death within twenty-four hours, which is suggestive in the patient's mind of the swellings from which she herself has sufdaughters. The second daughter, æt. 22, had had swellings in many different parts of the skin since the age of 12.

Dr. PARKES WEBER said that he had not considered Dr. Turney's case one of trophædema, but regarded it as a local infection producing chronic œdema, which he hoped would clear up. Dr. Savill's case had typical sclerodermia, which was well-known to produce chronic œdema; he thought the œdema in this case was analogous to the sclerodermia.

Dr. H. D. ROLLESTON did not regard the case shown as trophædema, for in that condition no thickening occurred. He had seen erythromelalgia follow trau-

matism.
Mr. C. Gordon Watson showed a case of DOUBLE INFANTILE COXA VARA TREATED BY SUBTRO-CHANTERIC OSTEOTOMY (WITH SKIAGRAMS).

Girl, then æt. 13, was admitted to the Metropolitan Hospital in December, 1907, with the history of deformity of hips and difficulty in walking since early childhood. There was no history of accident or illness. On admission she had a waddling gait, lordosis, and swung the body from side to side like a case of congenital dislocation. On examination of the hips the great trochanters were found to be greatly elevated. Abduction was practically abolished, but other movements at the hips were free, though limited. In dorsal decubitus the internal malleoli could only be separated Operation: December 10th, 1907-Tenotomy of adductores longi and other tense structures. December 17th, 1907—Double subtrochanteric osteotomy. On January 12th, 1908, a skiagram taken; left thigh accidentally refractured. January 20th, 1908, left thigh manipulated and put up again. At the present time (April, 1909), 16 months after operation, the legs can be abducted so that there is a distance of 36 in. between malleoli, and she walks well without waddling.

Mr. H. B. ROBINSON and Mr. W. H. Bowen showed

HEREDITARY TRANSMISSION OF CLAW HAND AND FOOT IN MOTHER AND CHILD.

Male, æt. 1, showed inherited claw foot. had a similar deformity of her feet, and in addition had deformed hands. The child's grandmother and great grandmother had similar deformities of the feet. A skiagram of the left foot showed the absence of the second metatarsal bone save for its proximal end. cleft in the foot corresponded to this bony deficiency.

The phalanges of the first metatarsal bone were present; those of the third and fourth bones were absent; and those of the fifth metatarsal bone were present, but the distal one of the two was turned outwards at right angles. The condition of the right foot was right angles. somewhat similar, but both the second and third metatarsal bones appeared to be absent, and the phalanges of the fifth metatarsal were not deflected. On the right side the great toe tended to point in an outward direction. In some of the cases of the deformity this outward deviation of the great toe was very pronounced, and tended to meet the inwardly deflected little toe produced the characteristic claw foot. The

family tree was exhibited.

Dr. A. M. Gossage said that the tree agreed well with the Mendelian law of heredity.

Dr. A. M. Gossage showed a case of COARCTATION OF THE AORTA.

Male, æt. 16, had always been rather short of breath, but had enjoyed fair health up to last October, when he was attacked with right facial paralysis from which he had since partially recovered. On examination there was some serious dyspnæa and marked pulsation of the carotids. The heart was hypertrophied, the radial pulse large, and with a sudden rise. There was pulsation and dulness in the second right interspace near the sternum. The superficial cardiac dulness came up to the fourth rib and to the right edge of the sternum. Systolic and diastolic murmurs could be heard over the aorta. Pulsation could not be felt in abdominal aorta, iliacs, or femorals. There was a small artery passing down on the right side of the epigastrium from the lower ribs to the umbilicus, and a small artery could also be felt in each axilla coursing down the sides of the thorax. Numerous small arteries passed at the back from the spine in the direction of the intercostal spaces under the skin. The aortic lesion was evidently congenital and probably in the usual position just above the junction of the ductus arteriosus with the aorta.

Mr. E. ARCHIBALD SMITH showed a case of

MULTIPLE CONCENITAL DEFORMITIES in a boy, 2 months old. The right tibia and left hip, and left patella were dislocated. The tibia was rotated outwards. There were extreme varus of the left ankle and umbilical and inguinal herniæ.

Mr. W. FEDDE FEDDEN read a paper on SIX CASES OF ACUTE INFECTIVE GANGRENE OF THE EXTREMITIES.

He said that apparently infective gangrene might be produced by a great variety of organisms—namely, the bacillus aerogenes capsulatus, bacillus coli, bacillus pyocyaneus, streptococcus pyogenes, and staphylococcus aureus. It was noteworthy that the bacillus of malignant cedema did not find a place in his series. The prognosis of cases due to bacillus aerogenes capsulatus was much more favourable than in those due to streptococcal infections, whilst those due to staphylococcus appeared to hold an intermediate position. The importance of early amputation was evident, and there was no time to wait for bacteriological data. should be our aim to amputate entirely through healthy tissue, but this was often impossible.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

MEETING HELD FRIDAY, APRIL 16TH, 1909.

The President, Dr. A. R. PARSONS, in the Chair.

CYSTS IN LIVER AND SPLEEN.

DR. PEACOCKE read a paper on cysts in liver and spleen, and gave some clinical particulars of the case from which the specimens exhibited were taken.

Professor Scott described the specimens. The liver was somewhat smaller than was usual, but the noticeable thing about it was the presence of half-a-dozen cysts spread around the margin, varying from one to two inches across. Each cyst was single. There was a single, somewhat small, cyst in the spleen. Sections under the microscopes showed numbers of flat cells. He believed they were not bile-cysts, but some form of lymphatic type.

SPLENO-MEDULLARY LEUKÆMIA.

Dr. ROWLETTE exhibited specimens of organs from a case of spleno-medullary leukæmia. The patient The patient was a woman, æt. 58. For many years she had been in good health, but had been treated once for some ondition of the heart. She was admitted to hospital in October last complaining of swelling of the feet. There was noticeable a very considerable swelling of the abdomen, and the whole of the left side was filled by a large tumour with a well-defined edge, reaching down to the left iliac region. Its greatest diameter was down to the left iliac region. Its greatest diameter was 16 inches. The blood was examined on October 18th, a fortnight after admission, and showed the red corpuscles to be 3,600,000, white cells numbered 040,000, and were of the usual type, except that one saw a larger number of "mast cells" than usual. The hæmoglobin was about 70 per cent. The condition of the blood left are doubt as to the diagnosis. tion of the blood left no doubt as to the diagnosis. The patient was treated with X-rays, and showed some Ine patient was treated with X-rays, and showed some improvement. In February an examination of the blood showed hæmoglobin about 80 per cent. The red corpuscles were considerably above the normal, and the white had fallen. The condition of the patient's heart was bad all the time, and she died in the beginning of March. The liver was very enlarged, and the heart had mitral disease, which was responsible in most part for the extreme passive congestion of the liver. The spleen was enormously congested. of the liver. The spleen was enormously congested. It was an interesting feature of the case that the red cells increased in number towards the end of life.

The PRESIDENT inquired as to the number of X-ray sittings, and as to whether there was any diminution of

the size of the spleen, or any change which might be attributed to the X-rays.

The Secretary said he had never seen a case of leukæmia with so little infiltration of the organs. more than one occasion he had the opportunity of testing the phagocytic power of the blood, and, while the influence of the serum in this regard appeared to be normal, he was forced to conclude that the phagocytic power of the polymorphonuclear leucocytes was considerably less than normal, and steadily lessened as the disease progressed.

Dr. Rowlette, in reply, said the patient was exposed to the X-rays about every second day, as a routine measure, from shortly after admission to hospital until shortly before her death. There was considerable diminution in the size of the spleen, but she was troubled with severe bleeding of the bowels, and the rays were suspended on a couple of occasions. He did not know that he could put down any definite condition to the rays. It was possible that the thickness of the capsule of the spleen might be attributable to

them, but he would not say so positively.

The Pathological Report of the Rotunda Hospital for the year 1908 was read, and the meeting adjourned.

# OPHTHALMOLOGICAL SUCIETY OF THE UNITED KINGDOM.

MEETING HELD AT THE ROOMS OF THE MEDICAL SOCIETY OF LONDON, THURSDAY, MAY 6TH, 1909.

The President, MR. R. MARCUS GUNN, F.R.C.S., in the Chair.

MAJOR R. H. ELLIOTT, I.M.S., exhibited instruments. (a) An evisceration spoon; (b) an optic nerve hook for use in the operation of optico-ciliary neurectomy; (c) an elevator for use in extirpation of the lacrymal sac.

Mr. Sydney Stephenson showed a case of congenital of patellæ, genu recurvatum, cryptorchidism, and other abnormalities.

Mr. G. WINFIELD ROLL showed a case with unusual appearance of the optic disc the result of a previous

Mr. E. TREACHER COLLINS showed a case of nodular leprosy affecting the eyes; also a case of progressive

bilateral ptosis.

Mr. HOLMES SPICER expressed the opinion that the condition was congenital, and thought the ptosis was closely allied to that in the cases of myasthenia gravis, which had been described.

Dr. G. CARPENTER read a paper entitled

A CLINICAL CONTRIBUTION TO THE STUDY OF TUBERCLE OF THE CHOROID.

The first patient, under Dr. Porter Parkinson, was vears of age. and had been getting thinner. Was 7 years of age, and had been getting thinner. admitted to hospital with physical signs at the right admitted to hospital with physical signs at the right apex, front and back. There was a history of abdominal pain, but no cause for it could be dis-covered by palpation. The child then became drowsy and comatose, with great wasting. There were six choroidal tubercles, and flecks of retinal pigment were scattered about them. Three of the tubercles were crossed by retinal vessels. A girl two years of age had been ailing six weeks, and had had sickness and headache five days. When admitted she was suffering from meningitis, and died on the sixth day. The right fundus was normal, and no tubercles or optic neuritis could be seen, but on the left side there was slight papillitis. Close to the optic papilla was a tubercle of considerable size, and several blood vessels crossed its face. The retinal arteries were small, nothing was noticed about the The surface vessels of the brain were con-The diagnosis was verified at the autopsy. gested. The next case was a boy, att. 17 months, who had much the same physical signs. He had meningitis, which was later corroborated by lumbar puncture. Another case was that of a boy, set. 2, who had had a bad cough five weeks, and when admitted had consolidation at both apices. There was a small amount of papillitis in both eyes. He died 12 days after admission, no changes having occurred in the fundus in the meantime. Several other cases of the kind were recorded, and the author then proceeded to discuss the readiness which had been shown to attribute such appearances to syphilis, whatever evidence to the contrary might have existed. He urged early and systematic ophthalmological examinations, which would often render unnecessary spinal punctures, or injections of substances to induce reactions.

The paper was discussed by the President and by Dr. Frederick E. Batten, the latter gentleman commenting on the comparative infrequency of tubercle of the chcroid in tuberculous children, and stating that he was under the impression that spinal puncture afforded a more certain indication than ophthalmo-

scopic observation.

Dr. CARPENTER replied.

Messrs. McKenzie Davidson and Arnold Lawson read a paper entitled a case of

SPRING CATARRH TREATED AND CURED BY RADIUM.

The patient was a boy, æt. 12, who suffered from chronic photophobia, lachrymation, and slight conjunctival discharge, which had persisted for nearly a year, but no exciting cause could be discovered. Both tarsi were covered with dense hard excrescences, closely aggregated, and separated by deep narrow fissures. The retro-tarsal tissue was swollen and hypertrophied, and the viscid discharge was spread over the conjunctival surface. The disease was confirmed by examination of the discharge. The irritability was chiefly marked in the morning. He was ordered complete cessation from close work, and was ordered complete cessation irrin close work, and dark glasses for out of doors. Yellow mercuric oxide was used, but no benefit resulted, and it caused too much pain. A week later he had cupric sulphate drops, of a strength of one to the ounce. In August the went to the seaside against his, Mr. Lawson's, advice, and got worse there. Bicarbonate of soda and hydrocyanic acid gave relief, and weak copper sulphate drops were used from time to time still. He then consulted with Mr. McKenzie Davidson as to the posconsider with Mr. McKenzie Davidson as to the pos-sibility of treating the case with radium. It was carried out for a year, during which period each eye was treated eight times. No pain or other immediate effect was produced, but the granulations gradually subsided. After the eighth application he was quite cured, but the interval before reading the communication was to make quite sure there had been no recurrence for a good time; 39 milligrammes of radium were used for 15 minutes at first, and then 44 milligrammes.

Mr. Lawson thought few applications with a potent dose of radium were better than many applications with a weaker quantity.

Mr. McKenzie Davidson discussed the case, pointing out the importance of being sure the strength of radium used was what it was said to be, as he had found serious discrepancies. It was also very important to cut off those radium emanations, which were not needed in the cure.

Mr. R. R. CRUISE read a paper on the ABUSE OF ATROPIN IN REFRACTION WORK.

The paper was based on the examination of 140 eyes in patients under 16 years of age. He concluded that, on the whole, homatropine and cocaine were quite equal, if not superior to, atropine, though in most cases the result after the two mydriatics was identical.

The paper was discussed by Mr. Stephenson, Mr. Bishop Harman, and Mr. Devereux Marshall, the latter of whom alluded to Mr. Lang's investigations on the matter; and Mr. Ernest Clarke said it would have been useful to learn what the astigmatism was in the cases.

Mr. Mayou read a communication on the disappearance of the iris from the pupillary area, following iniury.

# CORRESPONDENCE.

## FROM OUR SPECIAL CORRESPONDENTS ABROAD.

# FRANCE,

Paris, May 9th, 1909,

TAPPING FOR ASCITES.

GENERALLY speaking, ascites aggravates the condition of patients affected with this effusion in the abdominal cavity and constitutes a grave complication when the liquid is abundant.

It is thus that ever since the time of Hippocrates, the Father of Medicine, the operation of paracentesis has been practised, and generally to the great relief of the patient.

It must not, however, be forgotten that grave and sometimes mortal complications have followed para-centesis performed even under the most favourable conditions.

At the present day, the possibility of syncope a vacuo and acute peritoneal inflammation mentioned by older authors no longer exists, thanks to the use of fine trocars, antiseptic precautions and the position of the patient in the dorsal decubitus; but the possibility exists, and will always exist, says Dr. Perrin, of divers accidents, either immediate or consecutive. which it is well to know; even where the organic condition of the patient is the only responsible author, the reputation of the operator may be compromised. however unjustly.

These accidents may be grouped under five heads: serous anæmia, grave icterus, hæmorrhage of the abdominal wall, hæmorrhage of the digestive tract,

cardiac dilatation a vacuo.

It is customary to consider paracentesis as an insignificant and very simple operation, but as has been seen, in spite of all precautions, accidents are possible. Hence the necessity of the presiding surgeon to take measures against any avoidable accident.

Every patient for whom paracentesis becomes necessary, should have his heart examined and, if needs be, cardiac tonics should be prescribed several days before the operation.

A fine trocar should always be used, the patient placed in the horizontal position, and an abdominal bandage applied immediately after the operation.

The point of election for tapping is the junction of the middle and external third of a line drawn from the umbilicus to the iliac spine.

It is always prudent to inform one of the attendants that the operation does not always succeed, and to advise that in that particular case, a certain complication is possible.

VERTIGO.

In the course of chronic diseases, convalescence, and severe physical or mental strain, patients complain of vertigo, and this constitutes a very disagreeable symptom.

At the slightest effort, change of position or a simple emotion, they feel a loss of equilibrium, of obnubila-

Momentary vertigo rarely produces, however, a fall or loss of consciousness, yet it worries those who suffer from it.

Vertigo, a frequent symptom, proceeds from numerous and divers causes; cerebral and otic lesions, digestive troubles, cardiac and arterial affections, hepatic and renal insufficiency are frequent factors and require special treatment.

But the cases of vertigo already alluded to have another derivation, and are amenable to medication,

giving rapid results.

The majority of chronic maladies are accompanied by intense demineralisation of the whole organism. The physiological functions have not only to preside over the normal nutrition, but also to struggle against a condition of organic insufficiency. Under such conditions the waste of organic material affects an exaggerated rhythm, particularly as regards the constituent elements of the nervous system; these elements are: salts of soda, potash and magnesia. On these salts depends the function of the cerebro-spinal

In an organism exhausted by chronic disease, the demineralised nervous system, the cerebro-spinal axis, ill-nourished—become weakened and subject to slight functional intermittence, hence the same might be said of convalescence from acute diseases and

physical or mental strain. Án acute malady or muscular or intellectual fatigue, exhausts the mineral reserve of the organism. The nerve elements no longer find the quantity of soda, magnesia and potash necessary, and this mineral inanition shows itself by vertigo—a sensation of

emptiness in the head of intellectual impotence. It consequently behaves us to furnish the organism with the salts in question under the form of phosphate of soda, magnesia and potash, or as they may be found combined in a food preparation of the granular glycerophosphates, and under this treatment the disagreeable symptom of vertigo will rapidly disappear.

## EXTERNAL TUBERCULOSIS.

According to Dr. Calot, external tuberculosis may produce fatal results in three ways :-

(a) Amyloid degeneration of the liver or the kidneys, which causes nine-tenths of the deaths; it is due to the opening of the tuberculous abscess. A tuberculous abscess should never be opened. (b) Tuberculosis of the lung; avoided by keeping the patient as much as possible in the open air. (c) Meningitis, avoided by increasing the general resistance of the patient by procuring him absolute mental repose.

VOMITING

Stovain, 1 gr. Spirits of chloroform, 2 ozs. Peppermint water, 2 ozs. A tablespoonful every half hour. Acne of Young Girls. Resorcin, 15 grs. Lanolin, 6 drs. Olive oil, 2 drs.

# GERMANY.

Berlin, May 9th, 1909.

THE Deutsche Med. Zeitung, No. 34/09, has a reference to a paper on the INFLUENCE OF SALT ON THE COAGULATION OF THE

BLOOD. by Dr. C. Lichte. The following harmostatics are recognised: (1) Such as exert their action at the place of application, they are therefore entirely local; (2) such as exert an action at a distance.

The grouping may also be made in another way, the

hæmostatics being differentiated into the following, which act (a) by mechanical blocking of the vessel; (b) by contraction of the vessels (naturally the contraction must be general), or by contraction of the contractile tissue mass, in which the vessels implicated are situated; (c) by increasing the coagulability of the blood; (d) the so-called "aids" which indirectly obviate a long continued hæmorrhage (for example, hæmorrhage from the lungs which is obviated by the relief of cough by the derivatives of morphia)

Rarely has any hæmostatic any pronounced decided

action, independent of adrenalin.

Any effect is generally a combined one; for example, the vascular contraction and the mechanical blocking may be co-ordinated, or, one may follow the other, so that one effect brings up a supporting one, also (increase of the blood pressure, with local vascular contraction).

Those remedies with which the physician can exert action at a distance are of special importance. Gelatine gives the best distant effect. There is no longer any doubt of its efficiency, notwithstanding occasional

reports of failure.

Along with this, which has long been the object of scientific inquiry, is one the claims of which are equally high with that of gelatine, although its pharmacodynamics are so far unexplained. This old

folk remedy: common salt.

From the writer's personal investigations, he has drawn the following conclusions: there is a distinct drawn the following conclusions: there is a distinct raising of the coagulability of the blood after giving common salt, but only when the Na Cl is given in vivo, not in vitro. This effect, which is rarely absent when the blood is in a normal condition, appears after doses of 5 grm. of Na Cl, a small quantity in comparison with the usual therapeutic dose. Whether the effect of the dose is exhausted by the purely mechanical flooding as assumed by the writer, or whether a secondary positive catalytic effect is to be attributed to Na Cl or its ions in the individual phases of the act of coagulation cannot be said at present. The writer has also examined sodium bromide under conditions similar to those under which Na Cl was inquired into. The bromides are said to act as substitutes for salt, but not the iodides. The clinical experiences obtained by von Velden in the treatment of hæmoptysis by sodium bromide and Na Cl are in full agreement with those obtained experimentally by the author.

The same paper, No. 35, makes a reference to a

THE EXCITORS OF TRACHOMA,

by Prof. Greeff, Berlin.

He says they are regular round structures, distinctly smaller than the smallest known cocci. They are coloured intensively, sometimes a violet, sometimes a red after Giemsa, more feebly after aniline colours, not at all after Gram. They are surrounded by a clear yellow zone. With the highest powers it is sometimes seen distinctly that they are not a perfect globe, but somewhat oval, like bacteria with rounded edges. Where they are seen individually they show a tendency to divide into two, like diplococci. Trachoma granules must not be mistaken for eosinophile granules, as we see them in the leucocytes, which have not these properties. In later stages they lie together in large masses, the so-called "haufenform."

Halberstaedter and Prowaxek found the same

structures in trachomata in Java.

These structures only occur in trachoma; extensive control experiments had been made by others with negative results. Only quite fresh untreated cases need be examined for the structures. They lose their characteristic appearance very quickly after applica-tions with blue stone, even when there is no question of recovery. This is to be explained by the fact that the granules only disappear from the surface and are recruited from the deeper layers. They may be followed from the epithelium into the connective tissue, in threads often chainlike, the chains being reminiscent of streptococci. Both the writer and Leber had repeatedly seen them disseminated by white blood corpuscles.

# AUSTRIA.

## Vienna, May 9th, 1909.

## SUBFEBRILE TEMPERATURE IN TUBERCULOSIS.

At the Gesellschaft de Aerzte Engländer read a paper on the "Diagnostic Value and Therapy of Subfebrile Temperatures in Tuberculosis." He reminded the members of his method of taking temperatures from the urine which he introduced two years ago. During the last year he had employed that method in tubercular cases in Vienna and also in the Institution at Alland with the same result. In 75 cases he found 80 per cent. febrile or "high subfebrile." In suspected cases this temperature relationship was present; the "subfebrile" condition being an incontrovertible symptom in the case. In the Alland Institution he found cases where the temperature was normal in the armpit while the urine gave the "subfebrile" temperature. These parallel temperatures were present in 50 per cent. of the cases. He found also a very important symptom in these subfebrile temperatures, that if the patients were kept in bed they resumed the normal temperature in both urine and armpit. In most of these cases the most careful auscultation, percussion and radiography gave no manifestation of tuberculosis, hence the axillary temperature being perfectly normal and no other symptom of tuberculosis present, the case would be passed as one free from tubercle, but the urine temperature is a certain and safe guide in all doubtful cases.

Winternitz could not see the utility of this measuring of temperature in a funnel of filter paper in which a thermometer is placed. He thought the temperature of the anus and vagina, which were more accessible, would be more reliable than his urine method. With reference to the body temperature in the healthy, the temperature was not always found to be constant, as many causes were present to alter the reading, such as feeding. clothing, and rervous influences, which all had a varying effect on the temperature. The minimal morning temperature, which he has drawn attention to, we have always recognised as an early diagnostic sign of tuberculosis.

Weis remarked that in most of the phthisical cases an early temperature may be observed, but frequently this is not present in the first and second stages of the disease.

Engländer replied that by his own method, after all the symptoms and sputum had been carefully examined, this subfebrile sign was the most reliable in all suspected cases.

## LEIOMYOSARCOMA.

Paschkis next gave the history of a prostatic tumour which he had removed, whose microscopic structure proved to be a leiomyosarcoma, or Virchow's myoma lawicellulare.

## CEREBRAL GLIOMA.

Redlich exhibited a case which he had trepanned twice for epilepsy. The patient had the first fit about six years ago, after a heavy drinking bout, which repeated themselves at regular intervals. In the following year paresis in the right side set in, with congestion in both papillæ. A neoplasm was diagnosed in the motor centre of the left hemisphere, and as the attacks were becoming more frequent and severe, it was decided to operate in April, 1997. The trepannation revealed no morbid condition, and the wound was closed. After this the fits disappeared as well as the paralysis for a time. After a short interval the attacks began gradually to return in the form of Jackson's epilepsy, commencing in the right foot. Again the diagnosis of a tumour in the para-central lobe was made, with the result of a second operation, when an ill-defined glioma was discovered, and the greater portion of it removed. After healing, the right-sided paresis and epileptic fits have again returned.

Leischner said these were always very uncertain cases. In Eiselsberg's, in which he was engaged, 23 operations were performed for tumours in the brain, but only 18 were discovered, while 10 died immediately after the operation or during the healing of the wound. The results of the successful cases are also very discouraging and disappointing, as the disease recurs sooner or later, and the patient dies.

# FROM OUR SPECIAL CORRESPONDENTS AT HOME.

## SCOTLAND.

THE LATE PRINCIPAL MARSHALL LANG, ABERDEEN .-The venerable Principal of the University of Aberdeen, the Very Rev. John Marshall Lang, D.D., LL.D., C.V.O., died in Aberdeen on May 2nd. He had been ill for about four months. His illness began with an attack of blood-poisoning, which led to a toxic anæmia, and though he rallied in so far as to be able to attend to pressing business, he relapsed somewhat suddenly towards the end. Dr. Lang was one of the leading clergymen of the Church of Scotland. He succeeded Norman Macleod in the Barony Parish, Glasgow, and was an ex-Moderator of the General Assembly. He was appointed Principal of the University of Aberdeen in 1900, at a time when the affairs of the University were not in a satisfactory state. The extension scheme, initiated by his predecessor, Sir William Duguid Geddes, was on foot, but had almost come to a standstill when half-completed for want of funds. Money was needed and a vast amount of work had to be done ere Dr. Lang's unwearied efforts were crowned with success. Dr. Lang's appointment was looked on by many as a rather dangerous experiment, and his reception by the students was far from friendly. Time, however, justified the selection of Lord Balfour. Principal Lang's administrative capacity, his impartiality, tact, and courtesy, and the dignity with which he supported his high office, soon won for him the esteem of the community. His conduct of the Quater Centenary celebrations in 1906, and the part he played in bringing the University extension to a successful issue (which was largely due to the way in which he enlisted the sympathies of the citizens of Aberdeen in the scheme) were recognised by his having conferred on him the Commandership of the Royal Victorian Order, the highest honour which usage permits a clergyman to receive. Dr. Lang was an orator; he responded willingly to all calls made on his services, and as well entered into the social life of the town. He is survived by a widow, one daughter, and six sons, one of whom has recently been elevated to the Archbishopric of York.

## BELFAST

PUBLIC HEALTH.—At the monthly meeting of the Belfast Corporation, held last week, the chairman of the Public Health Committee, Dr. King-Kerr, gave statistics showing a marked decrease in notifications of infectious diseases during the past month. The total number of cases notified was 20 per cent. under the previous month, and 65 per cent. under the same month last year. The decrease applied to all notifiable diseases except cerebro-spinal meningitis, of which five cases were notified during the month, as against two the previous month, and 13 in the corresponding period last year. There was, nevertheless, a distinct rise in the death-rate for the month, this being due to the influenza epidemic now prevailing. The meat and milk supply still gives a great deal of trouble in inspection, which it seems impossible to make efficient. It was reported at this meeting that milk is being regularly sold in Belfast from dairies which are never inspected. Trouble has arisen, too, over the inspection of pork. The pork butchers naturally complain of carcases being seized and destroyed when found unsound in their possession, while hundreds of carcases of pigs are arriving by rail every night, the inspection of which is merely perfunctory. It would seem that only a largely increased staft of inspectors could cope with the amount of work to be done.

INFLUENZA.—There is at present in Belfast a widespread epidemic of influenza, happily, on the whole, not very severe, though in some cases quite troublesome enough. Medical men seem to be having more than their fair share of it. At the opening of the summer session no less than four of the teachers in the medical school were incapacitated by attacks of it.

# LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

# "GENERAL PRACTITIONERS AND MIDWIVES."

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—Permit me in closing this correspondence to express regret that I have not made clear what I meant in my letters, and that as a result Dr. Ross has misunderstood me. I have the very highest regard for "the General Practitioner," and for his interests and welfare, and do not yield to anyone in that respect. When in 1879 I began the Zenana Medical Mission College, it was because I had seen for myself the terrible physical conditions of the natives in India, Africa and China, etc., and became alive to the untold bodily misery of the women and children. I advo-cated the shortened curriculum, so that those poor untended natives should have some trained and skilled ministrations. At that time there were no lady doctors, and none at all to give service to those in agony, for men doctors would not be allowed near them. We do not call the St. John Ambulance-trained who give their services, in the absence of any others, to those needing their help, "quacks." Nor can we apply the name to those women and men who give their help, in the absence of all others, to sufferers who have no one to show them pity, men and women often give their lives to seek to relieve the class of sufferers of whom I write.

By all means send out men and women with the highest qualifications, if you can get them. But what are they in number amongst the millions without anyone whatever to minister to them in their times of suffering and agony? Since I raised the standard of need of help for the bodies of those to whom the misneed of help for the bodies of those to whom the missionaries were sent, and for the missionaries themselves, their wives and children, many first-class medical men and women—with the highest qualifications—have come forward, and placed themselves in the foremost ranks of the fighting line.

I am, Sir, yours truly,
G. DE G. GRIFFITH.

London, May, 1909.

"EMPTY POCKETS."

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—It is easy to be virtuous on ten thousand a ear. It is easy to be oblivious of the seamy side of medical life if one is earning a net income of from £2,000 to £10,000 a year. It is, no doubt, difficult to think much about the poor practitioner struggling to make both ends meet, if one is absorbed in purely scientific work; and equally difficult to realise his misery if one fills one of the few appointments in the service of the Municipality or State open to the profession, which place their holders beyond the danger of poverty. Your editorial note this week under the heading of this letter, and the letter of "G. P." suggest these and other reflections. If the rank and file of the profession wish to improve their lot, they must set to work, combine, and help themselves. The men who ought to be the help and leaders of their less fortunate brethren are too much engaged in their own life-work to have time, or strength, for any thing else. The one organisation, the British Medical Association, which seems the right body to give voice to professional claims upon the State and the public, does virtually nothing. For this reason it is, perhaps, that it numbers less than half the men on the Medical Register. It does a little to promote science in the way of providing endowment for research, but, beyond this, service of the Municipality or State open to the proof providing endowment for research, but, beyond this, nearly all its resources and forces are engaged in supplying a weekly journal at a low cost to the members. The journal, which costs a truly stupendous sum to produce, is not read out of the profession, and notoriously has no political influence. It would be equally useful, so far as promotion of the welfare of the profession is concerned, if it were reduced to half its present size, and if the funds saved were applied in other more useful directions. Is it not possible to form from among the 20,000 who are not members of the Association, and from the many dissatisfied members

within it, a society entirely devoted to safeguarding and improving the material interests of the profession. This would not interfere with or check the progress of science. We are all working in this direction. Medical men are all helping to improve the health of the people, either by purely scientific research by which the prevention of disease is made possible, or by the teaching of hygiene and sanitation in their daily work. The profession has tremendous claims upon the public and the State; but there is no one to enforce these claims unless they will do it for themselves.

I am, Sir, yours truly,

AN OBSCURE PRACTITIONER.

May 6th, 1909.

# THE ADMINISTRATION OF ANÆSTHETICS. To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The importance of the subject dealt with in your leading article of May 5th is so obvious that no apology is necessary for any attempt to place the matter in as clear a light as possible before the profession. In order to do so, there are two points which should be made quite clear. The first is the position of the so-called "quack dentist." This is really a most misleading title. Anyone who is not a registered medical or dental practitioner and yet practises the art of dentistry does so in defiance of the spirit, if not of the letter, of the law, and is liable to prosecution if he uses the title of dentist. The term "quack" is, no doubt, applicable to such an one, but the term dentist even with the qualifying prefix should not be used in his description. The use of such terms as "quack dentists" or "unregistered dentists" leads the public to suppose that those to whom it is applied occupy a recognised position, while in reality such is not the case. You further state in your article that the general medical and surgical training of the dentist is purely theoretical, and that they can have no scientific theoretical, and that they "can have no scientific knowledge of the effects of an anæsthetic, and no rules, other than rules of thumb, to guide them in their administrations." In the curriculum for dental students of the Royal College of Sur-geons in Ireland it is laid down that before qualification the dental student must not only quaincation the dental student must not only attend lectures in anatomy and physiology and pass examinations in these subjects, but he must also take out a special course of instruction in the administration of anæsthetics, and attend for twelve months the clinical practice of a general hospital. Furthermore, he must also pass a clinical examination in medicine and surgery. This being the case it would seem to us unfair that the dental student of the future should be and surgery. This being the case it would seem to us unfair that the dental student of the future should be deprived of the privilege, which the profession has so long enjoyed in the past, of administering anæsthetics to their patients. It should be also remembered that the most searching inquiries have failed to make out that the profession has in the past in any way abused this privilege. The number of deaths recorded as occurring during the administration of anæsthetics by qualified dentists compares, in every way, most favourably with the number recorded as occurring during the administration by medical men.

I am, Sir, yours truly,
T. PERCY C. KIRKPATRICK, M.D. Lower Baggot Street, Dublin, May 6th, 1909.

# OBITUARY.

DONALD RODERICK MORISON MURRAY, M.B., C.M.St.And.

WE regret to announce the death of Dr. D. R. Murray, one of the ablest practitioners in Leith. Dr. Murray, one or the ablest practitioners in Letti. Dr. Murray, who was in his sixtieth year, was born in Stornoway, and came to Edinburgh first as an Arts student, but subsequently entered Medicine. Thirty-two years ago he settled in Leith, where he built himself a large practice, and where for over twenty-five years he has been Admiralty surgeon and agent, with medical charge of the troops at Leith Fort, and the cavalry at Piershill on various occasions. Possessed of ability above the average, his skill as a practitioner made his name a household word in many circles, and

his vigorous personality, his genuineness, and his unfailing sympathy endeared him alike to patients and to friends, by whom his loss will be keenly felt.

GERALD FRANCIS YEO, M.D.Dub., F.R.C.S., F.R.S.

WE regret to record that the death of Dr. Gerald Francis Yeo, F.R.S., Emeritus Professor of Physiology at King's College, has taken place at his residence at Harbertonford, South Devon. Dr. Yeo was educated at Dungannon School and Trinity College, Dublin, and obtained the M.D. degree of Dublin University. He also qualified as a Fellow of the London College of Surgeons, and served as an Examiner in Physiology to the College, as well as to the Universities of London, Oxford, Cambridge, and the Royal College of Veterinary Surgeons. For fifteen years he was Honorary Secretary to the Physiological Society, and was elected a Fellow of the Royal Society in 1889. Dr. Yeo was born in Ireland in 1845.

# SPECIAL ARTICLES.

# THE POOR-LAW COMMISSION AND IRELAND.

THE Royal Commission on the Poor-laws and the Relief of Distress, which some time ago issued an exhaustive report dealing with the English portion of the inquiry, has now published its report on Ireland. There is, as in the case of England, a separate Minority Report, in which Prebendary Wakefield, Mr. F. Chandler, Mr. George Lansbury, and Mrs. Sydney Webb disagree with the Report of the Majority, and discuss the differences between the recommendations of the Majority and of the Viceregal Commission. To this Sir Henry Robinson and the Bishop of Ross, the Irish members of the Commission, append a rejoinder.
The following are the principal conclusions of the

Majority:—
That Boards of Guardians and general workhouses

be abolished.

That the County or County Borough be in future the area of administration and of charge for the relief of all classes of necessitous persons.

That the new local authority for the relief of the necessitous be known as the Public Assistance Authority and be a Statutory Committee of the County or County Borough Council.

Indoor Relief.—That we concur with the Vice-

regal Commission in recommending that there should be classification by institutions; that in each county the required number of the existing workhouses should be converted into specialised institutions for different

classes of inmates.

Medical Relief.—That the present dispensary medical service be a county service under the control of the Public Assistance Authority, and that the areas of the districts, where possible, be enlarged in view of

present population.

That County infirmaries, workhouse and other rateaided hospitals be co-ordinated, and that medical relief generally be under the management of the Public Assistance Authority, and that a County Ambulance system be established.

That a County Medical Superintendent Officer of Health be appointed, who shall also discharge the duties of Bacteriologist.

That Public Assistance Authorities have power to appoint nurses for nursing in the homes of the necessitous, in the same way as Boards of Guardians at present appoint midwives.

Outdoor Relief .- That outdoor relief be continued under proper safeguards and be chargeable over the whole area of the Public Assistance Authority.

Children.—That effective steps should be taken to secure that the maintenance of children in the workhouse be no longer recognised as a legitimate way of dealing with children.

The Aged and Infirm.—That the necessitous aged and infirm be accommodated in a number of specialised institutions, and preferably in small Homes or Alms Houses.

Lunatics, Idiots, etc.—That lunatics, idiots, and sane epileptics be maintained in asylums or institu-

tutions as recommended by the Viceregal Commission, and that disused workhouses be used as auxiliary

asylums for the purpose.

Unemployment.—That the existing provision for the relief of exceptional distress provided by Section 13 of the Local Government Act, 1898, is better adapted to the circumstances of Ireland than the Unemployed

Workman Act of 1905.

That the Unemployed Workman Act be discontinued.

The Minority of the Commission express dissent on several points, of which the following are the chief:-

The abolition not only of the Boards of Guardians, but also of all control by the elected representatives of the ratepayers over the public provision for the poor, and over the expenditure of the Poor Rate.

The establishment in each County and County

The establishment in each County and County Borough, of a new and wholly autonomous Poor-law body (under the name of "Public Assistance Authority"), on which the elected Councillors, of whom there need not necessarily be any at all, are expressly prevented from being in a majority.

In opposition to the proposals of the Viceregal Commission for the complete separation from the Poor-law of the whole transfer of the side it is now.

commission for the complete separation from the Poor-law of the whole treatment of the sick, it is now recommended that the whole Public Health service, including the County Bacteriologist, and all the County Infirmaries and Fever Hospitals, together with the Dispensaries, should become a Poor-law function; that the sick poor now under the County and County Borough Councils should become paupers; that the control of these County Infirmaries and Fever Hoscontrol of these County liminates and rever hos-pitals should be taken away from the County and Caunty Borough Councils, and handed over to the non-elective "Public Assistance Authorities" already described; and that the public treatment of tubercu-losis should be equally a matter for the Poor-law, and the Poor-law alone.

We entirely agree, too, with the recommendation of the Viceregal Commission that the treatment of the sick should be wholly removed from the relief of other classes, and should be entirely dissociated from pauperism. The English Poor-law and the Workhouse System, unhappily forced upon Ireland in 1838, have remained alien and abhorred. Ireland, even more for the policy of "Break up the Poor-law and abolish the Workhouse." In our judgment any attempt to set up a new Poor-law, and a new Poor-law Authority under whatever name—would be a repetition of the

mistake of 1838.

# THE PROPOSED DUTIES ON PETROL AND ON MOTOR CARS.

THERE are so many medical users of motor cars at the present time that a short statement of the probable effect of Mr. Lloyd George's new duties on motor cars and on petrol will be of interest.

In the first place the following scale of taxation

has

peen	propo	<b>SCU</b>					
Cars	under	61	h.p.	 ٠.	£2	2	О
,,			h.p.	 	3	3	О
,,		16	h.p.	 	4	4	О
,,	,,	26	h.p.	 • •	6		0
,,	,,	33	h.p.	 	8	8	О
,,			h.p.	 	10	10	0
,,	,,		h.p.	 	2 I	0	О
"	over			 	42	0	0

Medical men will obtain a rebate of 50 per cent. from this scale and, in the case of those who live in Great Britain, it is probable that this will in some cases mean a reduction of the present duty. On the other hand, at the present time there is no duty on cars in Ireland, and, consequently, whatever tax is now fixed is all so much direct increase in the case of Irish users. The horse-power will be calculated on the bore and number of the cylinders, as is done by the "Royal Automobile Club formula," and the length of the stroke of the piston-rod will not be taken into account. One consequence of this will doubtless be that the length of the stroke will be increased by the makers of cars to the utmost consistent with smooth running.

In the second place, a tax of three pence per gallon

has been proposed on all petrol used in motor cars. The amount which each car owner will pay under this head will, of course, vary according to the amount he uses his car and to its size. Assuming that a medical man runs five thousand miles in the course of a year, and his car averages twenty miles to the gallon of petrol, the annual loss by this tax will be £3 2s. 6d. This, however, is not all. The tax is to be collected from the importers of petrol, and as these gentlemen consider that they will be put to extra expense by having to comply with the requirements of the Inland Revenue, they have increased the price of petrol not by three pence but by four pence. This will mean a total increase in the price of the petrol used under the conditions mentioned above to £4 3s. 4d. If to this is added £1 10s. duty, the total extra cost of a small car for a medical man will come to £5 13s. 4d.

We have referred elsewhere to the necessity of

We have referred elsewhere to the necessity of medical men combining with the object of compelling Mr. Lloyd George to give them the same rebate as is given to other "commercial" users of petrol.

# MILITARY & NAVAL MEDICAL NOTES.

HIS EXCELLENCY THE GOVERNOR OF GIBRALTAR has appointed Major H. A. L. Howell, R.A.M.C., Medical Officer of Health during the temporary absence of Major C. E. P. Fowler, R.A.M.C., who is Medical Officer to the British Mission proceeding from Tangier to Fez to meet the Sultan of Morocco.

ARMY Medical Officers should, if possible, read a part of the book recently translated by Colonel Corvisart (formerly French Attaché at the Japanese Court), viz., "The Regulations of 14th October, 1907, on Field Service in the Japanese Army." These regulations replace those of February, 1900. The chapters on food, hygiene, and medical care will be found instructive, and the instructions in regard of obtaining "intelligence" extend to strictly questioning abandoned sick and wounded. The Japanese seem to have nothing to learn from European nations in the matter of their medical arrangements.

The following remarks on retired pay appear in the Army and Navy Gazette: Colonel H. Charlesworth, C.M.G., retired pay, R.A.M.C., who is now Senior Medical Officer Recruiting, St. George's Barracks, and whose services in the London district cease on 30th April, has been offered and has accepted Nottingham, where for some time past the recruiting work has been done by a civilian. The Director-General is being, as far as possible, most considerate to the retired medical officers in London who are to be replaced by full pay officers, by offering the former other vacancies where mostly civilians have been employed. It has been found that civilian employment is not quite so economical as that of retired pay officers, for we hear of some stations where the former draw as much as \$\( \)300 a year, while a retired medical officer could be similarly employed for \$\( \)150 per annum, just half the money. We understand that Sheffield is an example in point.

An important letter on "Medical Etiquette" appears in *The Pioneer Mail* (published at Allahabad, India). It bears the pseudonym of "Husband." It clearly indicates that medical officers in India are not as careful as they should be about disclosing and discussing the ailments of their patients. In a country like India, above all others, where gossip and curiosity are rife, there is the more need for a rigid secrecy such as has to be exercised by lawyers and priests.

SECUNDREABAD, in the Deccan, India, is a station where enteric fever is always more or less prevalent. Last month (March) Lieut.-Colonel Butt, the Senior

Medical Officer, was endeavouring to discover the cause of the prevalence of this disease in the station. He made a series of surprise visits to coffee shops, Army Temperance Association spots, and Soldiers' Home, the kitchen of which was closed for a week. Meantime a circular was issued warning the troops against bread and pastry turned out by a certain bakery, which has been ordered to be closed.

THE "Indian Subordinate Medical Department" is apparently smarting under the designation of their corps if we may judge from a long letter which appears in *The Pioneer Mail*, of 2nd April. The writer proposes that the rank and designation of the corps should be "Assistant Surgeon, Indian Medical Department," wishing the word "subordinate" to disappear. In like manner he says the title "honorary" lieutenant or captain should go by the board.

# REVIEWS OF BOOKS.

AIDS TO MEDICINE. (a)

This little book forms one of the well-known "Aids Series," published by Messrs. Bailliere, Tindall and Cox. The necessarily condensed nature of its information may be gathered from the fact that the bird's-eye view of contemporary modern medicine has been condensed into a compass somewhat short of 250 pages of small octavo. The previous edition was issued in four small volumes about the size of the present one, but it was found that this form was not full enough for a text-book, but too large for the purpose designed by the "Aids Series." Hence the revision and condensation into one volume. In its revised form it will be found a most useful and trustworthy companion when used in the right way. It is not, of course, intended to replace the larger text-books and manuals, but as a means of refreshing the memory as to the salient points of a subject that covers an immense and an ever-increasing extent of ground, we can imagine no more convenient outline map and guide-post, as it were, for the harassed student or the busy practitioner. In a short notice it is, of course, out of the question to enter into anything like a detailed criticism of the contents of a work like that under review. We shall content ourselves with saying that we have carefully read several sections of the book, and are satisfied with the accuracy of the statements. This would be expected from an author having Dr. Hudson's experience of hospital practice.

SURGERY: ITS PRINCIPLES AND PRACTICE. (b)

The fourth volume of Keen's well-known work deals more with special subjects than did any of its predecessors. The subjects discussed fall more or less into well-recognised groups, although the order in which they are treated does not correspond with such a division. Generally speaking these groups are:— Intestinal surgery, genito-urinary surgery, surgery of the ear, surgery of the eye, and, finally, naval, military and tropical surgery. There are fifteen chapters in all, and amongst the different contributors we notice the names of Drs. Bevan, Coley, de Schweinitz, Murphy, Rodman, Young, the Surgeon-General of the United States Army, and the Surgeon-General of the United States Navy. The list is a very representative one, though perhaps some of the contributors are not so well-known over here as were those to the former volumes.

The chapters on genito-urinary surgery occupy

<sup>(4) &</sup>quot;Aids to Medicine." By Bernard Hudson, M.D.Cantab..
M.R.C.P.Lond., Assistant Physician. City Road Hospital for Diseases
of the Chest, &c., &c. London: Bailliere, Tindall and Cox. 1909.

<sup>(</sup>b) "Surgery: its Principles and Practice, by various Authors." Edited by William W. Keen, M.D., LL.D., Emeritus Professor of Surgery and of Clinical Surgery, Jefferson Medical College, and John C. Da Costa, M.D., Professor of the Principles of Surgery and of Clinical Surgery, Jefferson Medical College, Philadelphia. Vol. IV. Pp. 1194, with 582 illustrations. Philadelphia: W. B. Saunders Company. 1908.

nearly half the book and deal in a most comprehensive manner with their subject. One chapter deals with the examination of the urine in relation to surgical measures, and surgeons would profit greatly by paying close attention to its advice. Chapters on the surgery of the kidney, ureter and suprarenal gland, of the bladder, of the prostate and the penis and urethra, and of the scrotum and testicles follow. Cystoscopic methods are clearly described, and the different forms of cystoscope are shown.

The chapters on intestinal surgery will also repay close study. They are written by Abbé, Van Hook, Kanavel, and Murphy.

The chapters on ear and eye surgery are very full, and constitute in themselves almost a monograph on the subject.

aph on the subject.
The chapters on naval and military surgery are
ide in their scope and of extreme interest. The wide in their scope and of extreme interest. chapter on military surgery discusses seriatim such subjects as organisation and administration, personnel, field hospitals, the medical department in the field, and the treatment of wounds in war. The chapter on naval surgery deals with battleship conditions of the present day, the medical department and preparation for battle, conduct of the medical department during battle, surgical conditions of naval warfare, conduct after battle, and hospital ships. It also contains some striking illustrations of wounds received during warfare.

We congratulate the editors and contributors on the excellence of the present volume.

# MEDICAL NEWS IN BRIEF.

## Child Study

PROFESSOR J. A. GREEN, of Sheffield, read a paper on "The Study of Types in the Mental Life of Children" at the Child Study Society Conference at Manchester University on the 8th inst. Professor Green said we had been told from time immemorial that we should respect the individuality of children. But it was idle to ask the teacher responsible for sixty children to have very much care for individuality in pupils. He referred sarcastically to the education theorists who maintained that the child in the course of its mental development recapitulated the history of the race. He thought the unfortunate part of such a method was that it started with a theory and looked for confirmation. The child mind was so delightfully complex, presenting so many facts to the observer, that nothing was easier than to find evidence of a theory of this kind. On the basis of this method the evident fear and recoil of the child when some grown-up person threatened "I'll eat you," indicated clearly a once cannibalistic period in the history of the race.

## Middlesex Hospital-Founder's Day.

THE Annual Middlesex Hospital Founder's Day Commemoration Service will be held in the hospital chapel on Wednesday, May 19th, at 3.30 p.m., when a sermon will be preached by the Rev. Herbert E. Guason, M.A., the chaplain. After the service visitors will have the opportunity of inspecting the wards of the hospital, and will be entertained at tea by the invitation of Lord Cheylesmore and members of the Weekly Board of Governors, in whose name the cards of invitation are issued.

# Midwives Act Committee.

THE eleventh meeting of the Departmental Committee appointed by the Lord President of the Council to consider the working of the Midwives Act was held at the Privy Council offices on May 5th, Mr. Almeric W. FitzRoy, Clerk of the Council, presiding. Evidence was tendered on behalf of the British Medical Association by the following witnesses:—Mr. J. Smith Whitaker, M.R.C.S., L.R.C.P., Medical Secretary of the Association; Mr. C. E. S. Fleming, M.R.C.S., L.R.C.P., Bradford-on-Avon; Dr. L. S. McManus, Wandsworth; and Mr. J. H. Taylor, M.B., Salford.

# Apothecarles' Hall, Dublin.

THE following candidates have passed the quarterly examinations of the Apothecaries' Hall, Dublin:—

First Professional.—In Biology: Simon Carroll, Joseph A. Moloney, George M. Mayberry, Bernard J. M. Neary, Michael O'Donnell. In Physics: Michael O'Donnell. In Chemistry: Bernard J. M. Neary, Completed Examination: George M. Mayberry, Bernard J. M. Neary, Michael O'Donnell.

Second Professional.—In Physiology and Histology: George M. Mayberry.

Second Professional.—In Physiology and Histology: George M. Mayberry.
Third Professional.—In Pharmacy: Edward Murphy, Jeremiah J. O'Mullane, George Andeen.
In Pathology: Jeremiah J. O'Mullane. In Medical Jurisprudence and Hygiene: Jeremiah J. O'Mullane.
Completed Examination: Edward Murphy, Jeremiah J. O'Mullane. J. O'Mullane, George Andeen.

J. O'Mullane, George Andeen.

Final Professional.—In Medicine: George Andeen,
Jeremiah J. O'Mullane. In Surgery: Jeremiah J.
O'Mullane, George H. Fisher, James H. Nichol,
James Stuart. In Ophthalmology: Jeremiah J.
O'Mullane, James H. Nichol, James Stuart. In
Midwifery and Gynæcology: George Andeen, S. E.
David, Edward Murphy, Jeremiah J. O'Mullane.
Completed Examination: George H. Fisher, Jeremiah
J. O'Mullane, James H. Nichol, S. E. David.

## Conjoint Examinations in Ireland.

THE following candidates have passed the Third Professional Examination of the Royal College of Physicians and the Royal College of Surgeons, April, Physicians and the Royal College of Surgeons, April, 1999;—C. E. Drennan, M. Drummond, R. A. W. Ford, G. J. Fraser, J. Gormley, P. Grace, F. J. Graham, L. A. Moran, H. H. Montgomery, J. McMullin, T. B. Newman, R. O'Connor, M. A. O'Callaghan, W. Rahily, A. A. Russo, H. C. Smyth, T. M. Thomson, F. W. Warren, R. H. Weir.

THE Chemists' Exhibition of this year is in full swing at the Royal Horticultural Hall, Vincent Square, Westminster. Medical visitors will find much practical interest in the exhibition, which is always replete with the latest novelties in pharmacy and allied matters. The exhibition week closes on May 14th.

# **NOTICES TO** CORRESPONDENTS. &c.

CORRESPONDENTS requiring a reply in this column are par-ticularly requested to make use of a Distinctive Signature or Initial, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much con-fusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIFTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home cr abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), &s. 6d. per insertion; 6d. per line beyond.

6d. Per line beyond.

Zenana.—Your views upon measles are shared by a great and increasing number of persons, both lay and medical in Liverpool last week it was pointed out, in a report of the Health Committee, that a quarter of the total number of deaths were due to measles, and one of the aldermen suggested that a special municipal research should be instituted with a view of finding a remedy for the disease. One of the great obstacles is the deep-rooted belief that measles is inevitable, and that it is a malady of little moment.

A GOOD YEAR'S WORK.

The annual statement of the Chairman of the Metropolitan Asylums Board last week showed that there had been no failing off either in amount or in efficiency of the excellent ambulance work of that body. During the year the removals numbered 59,870, with a mileage of 421,594 miles, and the record of entire freedom from accident involving injury to patients had been maintained. The use of motor omnibuses proved successful and economical.

economical.

J. H. Maclea.—A diet chiefly composed of tea, bread and cheese is certainly not calculated to encourage a strong and enduring race. It will be a bad day for Scotland should its country workers abandon their porridge. Milk, bacon and butter or lard added to bread and cheese would form a good basis—and tea in moderation is, of course, preferable to alcohol. The baked beans which form so important an article of diet with the American rural population might with great advantage be introduced to the United Kingdom. Baked beans are now being largely imported in tins, and are of excellent flavour and quality.

the Newton and Linsualized Guardians.

SHINGLETON-SMITH, LIONEL, M.B., B.C.Cantab., L.R.C.P.Lond., M.R.C.S., Medical Officer to the Brecknock Union (Brecon) Workhouse.

SHORTEN, W. J., L.R.C.P. and S.Edin., L.F.P.S.Glasg., Certifying Surgeon under the Factory and Workshop Act for the Duncannon District of the county of Waterford.

# Bacancies.

Children's Hospital Dublin.—House Surgeon. Salary, at the rate of 50 guineas per annum and extras. Immediate application to Hon. Secretary, Medical Board. (See advt.)

Brighton, Hove, and Preston Dispensary.—House Surgeon. Salary, 2130 per annum, with board and residence. Applications to the Assistant Secretary, 113 Queen's Road, Brighton.

National Hospital for the Paralysed and Epileptic, Queen Square. Bloomsbury, London, W.C.—Senior Dispenser. Salary, 2150 per annum. Applications to Godfrey H. Hamilton, Secretary. West Riding Asylum, Wakefield.—Assistant Medical Officer. Salary, £150 per annum, with apartments, board, washing, and attendance. Applications to the Medical Director.

Berks County Asylum, Wallingford.—Second Assistant Medical Officer. Salary, £140 per annum, with board, furnished apartments, attendance, etc. Applications to the Medical Superintendent.

Superincendent.

The Hospital for Sick Children, Great Ormond Street, London,
W.C.—House Surgeon. Salary, six months £30, washing
allowance £2 10s., and board and residence in the Hospital.

Applications to the Secretary. (See advt.)

# Births.

Bunder.—On May 2nd, at "Endrick Bank," Honor Oak Park,
London, the wife of H. Marchant Bundey, M.B., C.M., of a
son. Australian papers please copy.
MICKLETMAIT.—On May 6th, at Hasilington, Crewe, the wife of
George W. Micklethwalt, M.D., of a daughter.

# Marriages.

BAKER—PARROTT.—On April 29th, at St. Mary's Hayes, F. C. J.
Baker, M.R.C.S., L.R.C.P., of North Molton, Devon, to Stella
Caroline, younger daughter of E. J. Parrott, M.R.C.S.,
L.R.C.P., of Hayes, Middlesex.
BOTS—WIX.—On May 8th, at St. Albans Abbey, Julius Claude,
second son of A. H. Boys, M.R.C.S., L.R.C.P., of St. Albans,
to Katharine Mary, youngest daughter of F. N. Wix, H.M.I.,
of St. Albans. of St. Albans.

# Peaths.

CHAFFERS.—On May 4th, at Abbotsrood, Grange-over-Sands, Edward Chaffers, F.R.C.S.Lond., J.P., aged 67.

Holdbrooke.—On May 6th, at Station Hospital, Poona, Cecil Holbrooke, Capt. R.A.M.C., youngest son of the Rev. F. G. Holbrooke, rector of Kimpton.

Hubson.—On May 8th, at Bank House, Bootle Station, Cumberland, Thomas Watson Hudson, M.R.C.S., aged 78.

Kynset.—On April 27th, at 12 Priory Grove, The Boltons, London.

Herbert Arthur Kynsey, M.R.C.S., L.R.C.P., D.P.H., only son of the late Sir William Raymond Kynsey, C.M.G., Kk., aged 41.

aged 41.

Martin.—On May 7th, at Westfield, Surbiton, Henry Arthur
Martin, M.D., late Army Medical Dept., in his 71st year.

RAMBAT.—On April 29th, at Cotswold Sanatorium, Herbert Murray
Ramssy, F.R.C.S., of 35a Hertford Street, London, aged 45.

KNOLL & CO.

LONDON.

# HOMMEL'S Hæmatogen

CONTAINS NEITHER ALCOHOL NOR ANTISEPTICS

A combination of 80 parts purified and concentrated Hæmoglobin with 20 parts chemically pure Glycerine and Aromatic Flavouring.

The best of all the existing preparations of Hæmoglobin. More efficacious than Cod-Liver Oil or the ordinary manufactured preparations of Iron. Very strengthening both for Children and Adults. An energetic Blood Former. Increases the Appetite. Aids Digestion.

- Extremely useful in Rickets, Scrofula, General Debility, Anæmia, Weak Heart, Neurasthenia, and Convalescence from illness such as Pneumonia or Influenza.
- Unsurpassed as a Strengthening Restorative in Diseases of the Lungs. Has a very agreeable taste, and is taken with the utmost relish even by Children.

FREE FROM BACTERIAL GROWTH. UNCHANGED BY KEEPING.

These important qualities are guaranteed by using the highest permissible temperature in the process of manufacture (130° to 140° Fahr. for 24 hours). No guarantee of this description is possible for preparations made by a cold process with ether.

in prescribing, always state "HOMMEL'S" Hæmatogen as spurious imitations are offered.

ONLY SUPPLIED IN FLUID, NOT IN CAPSULES OR OTHER FORMS.

Infants - Take from Half to One Teaspoonful twice a day in milk.

Children - One or Two Dessertspoonfuls daily, either pure or mixed with any convenient liquid.

Adults - One Tablespoonful wice a day before the two principal meals.

# The New Dietetic Preparation.

OVALTINE is a dietetic preparation—in granular powder form—of high therapeutic value, made of Malt Extract, Fresh Eggs, Milk, and Converted Cocoa, and containing Active Lecithin.

Extremely Nourishing and highly Restorative.

Very Palatable and acceptable to the most delicate stomach.

Simple to prepare.

The best substitute for Tea, Coffee, &c., and the only preparation of this kind containing Organic Phosphorus (Lecithin).

A powerful Digestive Agent and a Nervine Tonic of the highest order.

# OVALTINE

is the remedy par excellence in Convalescence, Neurasthenia, Faulty Digestion, Malnutrition, Brain Fag, Over Study, and Exhaustion.

Readily assimilated and particularly adapted for the over-feeding of the Tuberculous. Suitable for infants, youths, adults, and the aged.

OVALTINE is packed in  $4\frac{1}{2}$  oz., 9 oz. and 18 oz. tins. LITERATURE AND SAMPLE FREE TO MEDICAL MEN.

A. WANDER, Ph.D., Manufacturing Chemist, 1 Leonard St., City Rd., LONDON, E.C.

# BACTERIAL VACCINES

prepared in the Vaccine Laboratory of the Department for Therapeutical Inoculation, St. Mary's Hospital, London, W., under the supervision of the Director, Sir A. E. Wright, M.D., F.R.S., etc.

# STAPHYLOCOCCUS VACCINE.

Prepared from cultures of various strains of staphylococcus.

Applicable to the treatment of ordinary furunculosis, suppurating acne, staphylococcic sycosis and all other forms of staphylococcus infection.

Supplied in three dilutions, respectively containing 100. 500 and 1000 millions of staphylococci per c.c.

# ACNE VACCINES (2 varieties).

Acne Bacillus Vaccine, applicable where the acne bacillus is predominant and the staphylococcus, if present, is quite a subordinate factor, as in non-pustular cases in which comedones form the principal feature.

Supplied in two dilutions, respectively containing 10 and 20 millions of bacilli per c.c.

Mixed Vaccine for Acne, applicable where the staphylococcus and the acne bacillus are both present as pathogenetic agents, as in cases in which the lesions assume a sub-furuncular form.

Supplied in a dilution containing 500 millions of staphylococci and 20 millions of sene bacilli per c.c.

# GONOCOCCUS VACCINE.

Prepared from cultures of gonococcus. Applicable to the treatment of genecoccal urethritis and chronic gonococcal rheumatism.

Supplied in two dilutions, respectively containing 5 and 50 millions of gonococci per e.e.

## STREPTOCOCCUS VACCINE.

Prepared from cultures of streptococcus isolated from cases of erysipelas. Applicable to the treatment of streptococcal lymphangitis, erysipelas, and other strictly localised forms of streptococcus infection.

Supplied in two dilutions, respectively containing 5 and 20 millions of streptococci per c.c.

# **NEOFORMANS VACCINE.**

Prepared from cultures of micrococcus neoformans (Doyen), which is present in most, if not all, malignant tumours, and, though not to be regarded as the causal agent, is probably responsible for inflammatory changes and the pain associated therewith, as well as for much of the cachexia.

NEOFORMANS VACCINE is not suggested as a substitute for surgical procedures or as a remedial agent, but as an auxiliary in the treatment of cancer which is found to suppress local inflammation and apparently to diminish the cachexia.

Supplied in a concentration containing 30 millions of

# TUBERCLE VACCINE (Tuberculin-Bacillary Emulsion).

Applicable in particular to the treatment of chronic, strictly localised, and apprexic tubercular affections.

Supplied in two dilutions, respectively containing in each c.o. 1-2000 and 1-5000 milligramme of the comminuted tubercle culture.

The above-mentioned vaccines are supplied in hermetically-sealed glass bulbs containing rather more than 1 c.c., also in bottles of 25 c.c.

# TYPHOID VACCINE (for preventive inoculation).

Prepared from cultures of the typhoid bacillus. In two dilutions, containing, respectively, 1000 and 2000 millions of bacilli per c.c.
Supplied in sets containing one bulb of each dilution, providing complete treatment for one individual.

A pamphlet on "Vaccine Therapy" with general instructions for the use of these vaccines will be forwarded on request. Reference is also suggested to the articles published in *The Lancet* of Sept. 26, 1908, p. 925, and April 10, 1909, p. 1035.

"A distinct advance on Easton's Syrup."

YNIN' AMARA is an analogue of Easton's Syrup, in which the sugar is replaced by an active Malt Extract. This affords a far better vehicle than syrup, as it is actively digestive and nutritious, and there is not the likelihood of the sugar crystallizing out, and carrying down in the crystal the alkaloid principle.

As a digestive tonic, the efore, 'BYNIN' AMARA is not only safer to take than Easton's Syrup, but is of greater value both in aiding and strengthening the powers of assimilation.

It has been found very effective in neuralgia and similar nerve troubles.

# COMPOSITION.

Quinine Phosphate					1½ grains.
Iron Phosphate					2 ,,
Nux Vomica Alkaloids	equal	to	Strychn	ine	16 ,,
'Bynin, Liquid Malt					1 ounce.

Dose for Adults-One dessert to one table-spoonful, suitably diluted.

A Sample Bottle will be sent free to Medical Men, on request.

## Notes and COMMENTS.

More Dental

THE campaign against unqualified dental practitioners goes on, and success beyond anything previously Prosecutions. anticipated crowns the efforts of the prosecutors. Last week a Mr. E. L.

Robertson, of Brixton, was convicted and fined £10, and £2 2s. costs, by Mr. Hopkins, at Lambeth, for unlawfully taking and using an addition or description implying that he was registered, and that he was a person specially qualified to practise dentistry. The defendant pleaded guilty to the technical offence, though he contended that he had correctly stated his qualifications. On the same day, at the North London Police Court, Mr. Howard Bennett, of Hackney, was also summoned, he having been fined £10, and £3 3s. costs, for the same offence as recently as March last. Since that conviction, in order to regularise his position, he had put on his brass-plate the words, "not registered under the Act of 1878." The magistrate, however, held that the Act precluded the defendant from putting up any description implying that he was a dentist. He thought it permissible to put up a case of false teeth and the practitioner's name, but nothing else. Consequently he fined him £20, and £5 5s. costs. The day of the quack dentist seems drawing to a close, and, like the unqualified medical assistant, he will probably disappear from the scene.

WE do not remember the point Who pays having arisen in a court of law as the to whether the patient or the attend-Consultant? ing practitioner is responsible for the consultant's fee, but it was raised in the Romford County Court last week, and, unfortunately, not settled, owing to side issues. The parties to the action were Dr. W. Summerskill, as plaintiff, and Dr. Shepherd, as defendant, the former claiming for the return of certain articles and for board and lodging, the latter counter-claiming for professional fees for consultations. The judge decided against Dr. Shepherd on other grounds, so that the point, legally, remains in abeyance. It is deplorable enough that disputes of this kind should arise between medical men and be decided in public courts, and the fact that such differences may arise at any moment forms another of the strong arguments for joining one of the defence societies, as the councils of such bodies are always prepared to arbitrate, or to appoint an arbitrator, to decide matters in conflict between medical practitioners. Moreover, when such arbitration is offered by one party, and declined by the other, there can be little doubt as to which way the feeling of the profession would incline. The dignity of the profession demands that only in the last resort should fellow-practitioners fight each other in the law courts.

Divided

As to the point at issue, namely, responsibility for the consultant's Divided fee, we take it that no general rule Responsibilities. can be laid down. If the patient

or his friends wish to have the advice of a particular practitioner, and ask him directly to meet the usual attendant, there can be no doubt that they are liable. On the other hand, when the attendant asks for a consultation, and suggests a practitioner, and makes the arrangements himself, we gather that he thereby directly takes the responsibility himself, and he is therefore wise to see that the fee is forthcoming and paid over to the consultant before he leaves the patient's house. But between these two types of case there are many others, such as when the friends ask for consultation and leave arrangements to the attendant, or when the attendant requires a consultation, and leaves the friends to make an arrangement with a medical man of their choice, in which the responsibility is more evenly divided. Although a consultation is primarily undertaken for the benefit of the patient, it is also, in most cases, at any rate, a direct benefit to the attendant, both by relieving him of responsibility and strengthening his position, and it might be held in some cases that as he is a beneficiary he is concerned in the payment. But only in the most extreme cases can we imagine a consultant suing a brother practitioner for his fee.

A case of suicide which was remarkable in two ways
just been inquired into by
Dean Forest Coroner. In Euthanasia has the 10 Suicide. In the first place, the Coroner is himself a medical man, and the subject of the inquest was a patient of his own. Under such circumstances we cannot help feeling that, from the point of view of public policy, it would have been wiser had the inquest been held by his deputy. We hold that a coroner's duties are the functions, properly, of a medical man, and we should like to see all coroners trained medical men, but if cases like the present one arise they are sure to be quoted by those who consider the coroner's office is one for a lawyer. The other feature of this inquest was the coroner's evidence that the patient was suffering terrible agony from a malignant growth of the throat, and that he begged that something might be given "to send him out of the world quietly." In spite of reasoning and en-encouragement, the poor fellow said that no one could form any idea of his sufferings, but that he would try to endure them to the end. Subsequently he was found at the bottom of a well. Tragedies

so real and terrible as this one forcibly raise the question as to whether some official machinery should not be set up whereby sufferers from in-curable and intolerable diseases might be set free from their sufferings.

SEVERAL cases have occurred of late Medical in which medical men have unwit-Certificates for tingly granted to midwives certifi-Midwives. cates of good character, afterwards

shown to have been contrary to fact. There is, of course, no more absolute moral obligation in granting such a certificate than in giving the ordinary "character" to a domestic servant. In the case of midwives, however, the law has seen right to attach a greater degree of responsibility. In another column a brief report is given of a police court prosecution at Eccles, in which a midwife was accused of having gained admission to the midwives roll by a false and fraudulent certificate of good moral character, and a medical man for having granted the certificate. It was alleged that the midwife had more than a dozen convictions against her for drunk and disorderly conduct. The medical man was defended by the Medical Defence Union, and it was contended on his behalf that he had always found the female defendant capable for her business. The charge against the medical man was dismissed, but the midwife was committed for trial. The case shows that medical men should be extremely cautious in giving certificates of good character to midwives, as otherwise they may find themselves involved in extremely unpleasant consequences.

THE question of disputed responsibility bility for fees comes, sooner or later, within the average of the control of the contr for Fees.

cal practitioners. Some friend or relative engages the services of a medical man, but attempts to evade payment when that stage of the transaction is reached. The hands of the profession will be strengthened by a judgment given on May 3rd by Judge Bacon, in the Bloomsbury County Court. In the case concerned an action was brought by a medical man to recover fourteen guineas for certain professional services. Plaintiff stated he was consulted by defendant concerning the mental condition of a friend of hers, and he was given to understand she herself would be responsible for the fees. The reason for consulting him was that she wished the patient removed in order to prevent her marrying a gentleman she wished to marry herself. Apart from motives, however, we are glad to find that the judge took a clear and strong view of the legal position, namely, that plaintiff was entitled to his

within the experience of most medi-

" Preak "

plaintiff in her own interests.

WE have been accustomed to think that " freak " advertising had reached its highest point of development in Advertising. America, but last week we received a French circular which fairly out-

Herods anything we have ever met with before. No doubt our readers have received similar attentions from the firm in question, which, by the bye, is engaged in purveying a meat-juice. The circular bears on its outer cover a picture before which the indecent vulgarities of the more reptilian French comic papers might fairly blush. The scene depicted is that of an anatomist or surgeon dissecting a woman. One half of the latter figure is that of a naked courtesan smoking a cigarette, while the

fees, with costs. In this case the defendant was

not a relative of the patient, and admitted, under

cross-examination, that she had consulted the

other half shows her partially-dissected limbs. The mise-en-scène suggests rather the harlot's chamber than anything else, and the whole picture is repulsive in its suggestion of a connection between science and lust. What purpose the firm seek to subserve by such an atrocious outrage on good taste we fail to perceive, but it may perhaps be reassuring to them to learn that in this country any medical man who appeared to countenance such an advertisement would receive, deservedly, the reprobation of his fellows.

# LEADING ARTICLES.

GRINDERS' PHTHISIS AND DUST.

LAST week an important Home Office inquiry was opened at the Sheffield Town Hall concerning the disease alleged to be due to the unhealthy conditions under which the grinders of that city conduct their work. Despite the great advances that have been made since the old days of drygrinding, the mortality in certain "dusty" industries is still excessive. For instance, taking 100 as the death-rate from consumption amongst agriculturists, who are the healthiest class of the community, we find that there are several occupations in which the mortality is multiplied to the extent of three to four and a half times that ratio. The precise figures are: Potters, 453; cutlers, 407; file-makers, 373; glass-makers, 335; and coppermakers, 317. With regard to these figures, it may at once be unhesitatingly said that they represent an enormous and preventable waste of human life. It is peculiarly appropriate that the inquiry into this important matter should be raised in Sheffield, where, thanks to the labours of the late Mr. Simeon Snell and others the question of grinders' phthisis was long ago threshed out, and the modern crusade against industrial disease inaugurated. Much has been accomplished, but, with the above-quoted figues in view, it is equally evident that a vast deal remains to be accomplished. The ideal goal would be the reduction of serious respiratory diseases in the "dusty" trades to a level little above that of the agriculturist. Dust there must always be in connection with certain industries, but there are various ways in which the resulting risks may be materially diminished. The representative of the Cutlers' Company, Colonel Hughes, appears to have grasped the fundamental fact, that it is the quality of the dust which is the key to the position. Ordinary workshop dust may irritate the respiratory passages, but does not in itself produce phthisis, unless there be primary or secondary infection with the specific organism of tuberculosis. This proposition appears to be so self-evident and elementary that it is difficult to realise that in so important a trade centre as that of Sheffield it has not long ago been reduced to the working basis of a by-law. If, however, we turn to the history of sanitary progress generally, we find that it has in the main depended upon the tardy recognition by administrative bodies of more or less self-evident sanitary principles. At any rate, among the first facts elicited by the official inquiry is the crucial point that no steps are taken to exclude tuberculous grinders from the workshops, and that they are permitted to spit about the sheds without let or hindrance. Under such circumstances it appears to be somewhat of a farce

to take elaborate precautions to remove the mechanical dust which simply irritates the respiratory lungs, but to permit the constant contamination of the sheds by the sputum of tuberculous persons. Nay, more than that, it seems not improbable that by withdrawing the infected dust from the workshop the sanitary authorities may be distributing it broadcast and actively infective to the outside world. From a logical point of view, it is obviously necessary to get rid of the great predisposing factor in the spread of industrial phthisis, namely, dust. Then comes the problem of how to eliminate the specific germs of tuberculosis, which must reach the damaged lung by some route or other before the disease can be developed. One most elementary precaution is clearly to render the environment of the workshops as free from the tubercle bacillus in as thorough a manner as may be rendered possible by modern sanitary measures. This part of the problem, indeed, seems so self-apparent that we need not hesitate to anticipate the views of the Commissioner that in future regulations should be framed with a view of excluding tuberculous workpeople from the workshops, and of bringing under control the practice of spitting. These considerations suggest that there still remains much to be done in improving the environment of the factory and workshop. That something is radically wrong in the conditions of modern industrialism is shown by the testimony of Dr. Scurfield, the Medical Officer of Health for Sheffield, who has done excellent work in the past in the lessening of grinders' phthisis. He said the death-rate from that cause in his city was extraordinary, Birmingham being the only other town in England with anything like its record. The death-rate from phthisis among grinders was 15 per 1,000, as against 2.6 per 1,000 amongst all males over twenty years of age
—nearly six times as great. The death-rate was 5.6 per 1,000 from phthisis, as compared with 2.6 in the rest of the population, and from other respiratory diseases it was 7 per 1,000, compared with 2.1 per 1,000. Practically one-half of the grinders of Sheffield who had died during the past ten years had died of consumption. These facts point emphatically to the need of throwing fresh energy into the national fight against tuberculosis. It is only by the relentless extermination of all centres of infection that the battle will eventually be won. Meanwhile, the Sheffield Inquiry will have achieved much if it simply enforces the lesson that dust is a contributory, but not a prime, cause of industrial phthisis.

# CURRENT TOPICS.

The Future of Malaria Prevention.

One ever-present pitfall in administrative government lies in the determination of promotion. If by seniority alone, then it is tolerably certain that men will gradually rise to the most important posts, whether they have devoted themselves to the mastery of their professional work or otherwise. The square man in the round hole is an old-standing and familiar figure in official life. This risk has been lessened in some of the services by a preliminary weeding-out of unfit candidates by

competitive examinations. It seems probable that sooner or later the imposition of later examinations to test competency on promotion will become more or less the rule, more especially in those administrative branches that involve progressive technical knowledge. The general aspects of the problemwere vigorously dealt with in a direct fashion a short while since by Major Ronald Ross at the Royal Institution. He bewailed the failure of the hopes of the immediate success of the measures to combat malaria that were inaugurated ten years ago. "Malaria we know," he exclaimed, understand fully, we can beat down when we please. The battle which we are now fighting is against human stupidity." The gist of his criticism was that the sanitary administration of the West African Colonies had been wanting in leadership and organisation, and the campaign thwarted by administrative indifference and professional jealousy. He regretfully expressed his opinion that men, after receiving their medical qualifications, often went no further, read nothing, made no researches, and obtained the highest medical or sanitary appointments either by seniority or by the well-known acts of self-service and wire-pulling. This type of person was too common in all branches of British administration, and worse heads of departments could not be found. It is to be hoped that the Colonial Office will pay due heed to this crushing indictment, coming as it does from a man whose whole history forms a standing argument for the benefits that can be conferred upon communities by scientific and vigorous sanitary administration. In cur opinion the further statement by Major Ronald Ross that he has known young men in the Service who have been actually punished for acting as pioneers deserves authoritative investigation at the hands of His Majesty's Government.

# Objections to Post-mortem Examinations in Hospitals.

THE prejudice against interference with the human body after death is probably a natural one, and is, at any rate, one which must be reckoned with in our present civilisation. In the past it stood as an obstacle in the path of anatomical study, and at present in like manner it blocks the investigation of disease. No case of disease can be thoroughly studied without a complete examination of the body after death, and in private practice this is almost always impossible, and in hospital. work there are many difficulties in the way. In Ireland the feeling of the sanctity of the dead body is stronger than in England, and consequently it is even more difficult to co-ordinate the clinical facts with the anatomical conditions. The matter has long engaged the attention of those interested in the progress of medicine, but so far without much result. Lay committees are, as a rule, slow to adopt any stringent regulation on the subject, and consequently comparatively few bodies are available for pathological study. Much has yet to be done in the education of the public of all classes as to the reasons which require freedom of autopsy. Put in a nutshell, it is not, as is so often thought, mere curiosity which brings a physician to the postmortem room, but a desire that his next patient may have a better chance of life or of speedy

recovery. Early in the last century, in order to temove the prejudice against dissection, a number of enlightened and distinguished men made known their wish that their bodies should be dissected. It is possible that some similar pronouncement as regards post-mortem examination would do a little to dissipate public prejudices.

## Gratuitous Attendance in Street Cases.

THE more the medical profession does gratuitously for the good of the community, the greater the trespass made upon their good nature. The gratuitous attendance upon street accidents is a case in point. Such service is rendered, as a rule, by medical men without fee or reward, but there is no conceivable legal right on the part of anyone to demand gratuitous attendance of the kind. We are glad to see that the point has been vigorously taken up by the Hartlepool division of the British Medical Association. The immediate cause was a newspaper attack upon a local medical man who had been called to a street case, but was not informed of its serious nature, neither was he given an opportunity of attending the subsequent inquest. The Society also emphatically claim that it is no part of the duty of a district medical officer to attend street cases. They further submit that, as it is the duty of the police to look after injured persons, they should also call in and pay for medical attendance. The Hartlepool division certainly deserve the wholehearted support of their brethren in the attempt to induce the proper public authorities to act "with a view to the medical treatment of street accidents and emergencies being placed on a proper businesslike footing."

## How to Fight Urban Tuberculosis.

THE attempt to fight tuberculosis in the United Kingdom by the aid of huge and costly sanatoria has not proved an overwhelming success, to put the matter mildly. As a means of coping with the disease amongst the poor and the less wealthy middle classes the plan is practically useless. The idea of erecting great blocks of model tenements for the tuberculous poor of cities does not appear to have occurred to any of our leading sanitarians as a feasible and desirable scheme. It has remained for America to bring forward the proposal, and for an American millionaire, in the person of Mrs. Vanderbilt, to furnish the large sum of money required to reduce the scheme to a working basis. That kind-hearted lady has undertaken to build large blocks of tenements so constructed with gardens and balconies that it will be possible to carry out the open-air treatment. It is interesting to learn that this practical philanthropist has not only given a million dollars for the cause, but has actually visited the consumptives and studied their wants in their own homes. There is a good deal worth careful consideration in this new departure. The experiences of Mount Vernon Hospital show that tuberculous patients can sleep outside at all times of the year, even in the midst of a dense London fog. It would be a comparatively easy matter to fit up some small sanatoria experimentally on the lines adopted by Mrs. Vanderbilt, and it is to be hoped that British philanthropy would speedily rise to the occasion were it shown that the open-air tenement block is a suitable kind of building for the treatment of tuberculosis in our great centres of population.

# Operations v. Military Law.

THE value of the army as a military machine depends primarily and essentially on discipline, and the sacrifices that are necessary to that end are frequently great. A soldier who swears to obey his officers does so blindly, and, theoretically, if he is told to charge singly against a squadron of cavalry or a battery of artillery he has no option but to obey. Does his duty entail submission to the advice of his medical officer to undergo an operation? In the British Army we believe it does, though we have never heard of a case in which it was necessary to turn the advice into an order. The question has lately arisen in Germany, where a private refused to undergo an operation, and, with Teutonic thoroughness, he was promptly courtmartialled and sentenced for disobedience. His case, however, has excited much interest among jurists, and several eminent lawyers have come forward on his behalf to argue that surgical operations are outside the category of military duties, and therefore he has a right to refuse. If the refusal was unreasonable, and the disease interfered with military duties, we take it that this argument would not hold water, but in any case it is most undesirable that such stern steps should be taken, except in case of extreme necessity. In this country, at any rate, we hope that no similar case will arise. It can add nothing to the respect in which the profession is held, and might do a great deal to damage it.

# A New Method of Watching Operations.

THE difficulty of arranging matters so that students shall be enabled to watch surgical operations has greatly increased under modern methods. It is now necessary to restrict the number of those present to a minimum, as the risk of sepsis is increased by every additional person present. The cinematograph gets over the difficulty only to a limited extent, besides which it is costly and cumbrous. An American-Dr. Charles H. Duncanhas introduced a most ingenious plan whereby the students may sit in an adjoining room and watch every step of an operation at their leisure. Above the operators is a large disc, fitted at its periphery with a number of electric lights. By a series of lenses and mirrors a view of the area beneath the disc is projected on a screen in the students' room. As the picture is taken from above, every movement of the surgeons and every detail of the operation around is visible, and the inconvenience of the interposed bodies of surgeons and assistants, whereby the ordinary view of an operation is often completely spoiled is avoided. The educational value to students of witnessing actual operative procedure is so great that any method which renders that privilege more generally available will be hailed as a boon in the medical schools. The instrument is named a "projector."

# PERSONAL.

MISS FLORENCE NIGHTINGALE, O.M., entered her ninetieth year on May 12th last. We cordially offer her our congratulations.

THE authorities of the University of Toronto express great pleasure at the acceptance by Dr. Leathes, of London, of the Chair of Clinical Pathology at the University.

Dr. David N. Knox has been elected representative on the General Medical Council of the Glasgow Faculty of Physicians and Surgeons in succession to the late Dr. Lindsay Steven.

SIR SHIRLEY F. MURPHY was the recipient, on Thursday last, of the Honorary Fellowship of the Royal College of Surgeons of England. His membership dates from 1870.

MR. ERNEST MALLAM, D.M., Magdalen College, has been appointed Litchfield Clinical Lecturer in Medicine in the University of Oxford for a term of two years from October, 1909.

DR. STUART M'DONALD, M.D., F.R.C.P.Edin., of the University of Edinburgh, has received the important appointment as Professor of Pathology in the College of Medicine, Newcastle-on-Tyne.

Dr. James Hurd Keeling, M.D., of Sheffield, whose death was reported in these columns a few weeks since, has left £250 each to the Jessop Hospital for Women, Sheffield, and the Sheffield University.

DR. JOHN KEAY, Medical Superintendent of the Bangour Village Asylum, has been appointed, jointly with Sir J. Batty Tuke, Lecturer on Mental Diseases in the Extra-Mural School of Medicine, Edinburgh.

The honorary degree of LL.D. of the University of Liverpool was conferred on Sir Donald MacAlister, K.C.B., on May 8th. At the same congregation Dr. J. T. Todd was presented with the honorary degree of D.Sc.

PROFESSOR G. SIMS WOODHEAD, M.D., has been re-appointed by the Council of the Senate of the University of Cambridge as representative of the University of Cambridge on the Council of the Lister Institute of Preventive Medicine.

THE Poor-law Medical Officers' Association of England and Wales will hold its annual meeting this year on July 6th at the Guildhall, London, at which a conference will be opened on the report of the Royal Commission on Poor-law Medical Relief.

MR. CHARLES A. BALLANCE, M.V.O., F.R.C.S., Surgeon to St. Thomas's Hospital, was elected last week a member of the Court of Examiners, Royal College of Surgeons of England, in the vacancy occasioned by the retirement of Mr. A. Pearce Gould.

Dr. MAJOR GREENWOOD, jun., will give a course of four lectures on "Satistical Methods in Physiology and Medicine" at the London Hospital Medical College on May 21st, June 4th, 11th, and 18th. The lectures are at 4.30 p.m., and are free to all students of the London University.

SIR WILLIAM S. CHURCH, BART., K.C.B., M.D., will preside at the fourth annual meeting of the Convalescent Homes Association to-morrow, Thursday, May

20th, at 4.30 p.m. The report for the year 1908 will be submitted, and the object and work of the Association will be explained.

PROFESSOR PFEIFFER, Director of the Hygienic Institute, Breslau, will deliver the Harben Lectures of the Royal Institute of Public Health this year. The lectures will be given on June 21st, 23rd, and 25th, at 6 p.m., and will deal with subjects connected with immunisation and virulence.

M. PAUL CAMBON, the French Ambassador,, presided over the 41st Annual Dinner of the French Hospital, held on Saturday evening, at the Hotel Cecil, London. It was attended by the Spanish Ambassador, M. de Villa Urrutia, the Lord Mayor, Sir George Wyatt Truscott, and the Sheriffs.

THE Jacksonian Prize of the Royal College of Surgeons of England has been awarded to Mr. J. P. Lockhart Mummery, author of that very popular handbook, "The After-Treatment of Operations." The John Tomes Prize in Dental Surgery has been awarded to Mr. Arthur Swayne Underwood.

Dr. George H. Gibson will give the Opening Address at the Medical Faculty of the McGill University, Montreal, on September 22nd. His subject will be "The Limits of Knowledge." On June 9th Dr. Gibson is to have the honorary degree of LL.D. conferred upon him by the University.

AMONG the witnesses who appeared before the Departmental Committee to consider the working of the Midwives' Act, at their last meeting, were Mr. Sydney Stephenson. Dr. Sidney Barwise (Medical Officer of Health for Derbyshire), and Mr. Walter Schröder (Deputy-Coroner for the Central District of London).

MRS. MACLOGHLIN, late of Southport, has offered to the Royal College of Surgeons, London, a work in bronze and marble by Mr. Alfred Gilbert, M.V.O., The gift has been accepted with the best thanks of the council. The work, which is life-size, and portrays Mrs. Macloghlin and her late husband, Mr. E. Plantagenet Macloghlin, M.R.C.S., is to be placed in the entrance hall of the college.

WE regret to hear that Dr. Bucknall, when motoring from Hastings to Maidstone last week, met with a serious accident, when, on turning a very sharp corner just outside the former town, the car swerved on to a bank and overturned. Dr. Bucknall and his companion were thrown clear of the vehicle, and sustained serious injury, while the chauffeur, who was hurled over the edge, was picked up in an unconscious condition.

ROYAL ARMY MEDICAL CORPS.—Colonel H. J. R. Moberly, Maymyo, has been appointed officiating P.M.O., Presidency and Assam Brigades. Lieut.—Colonel F. P. Nichols has been appointed to the command of the station hospital, Jullundur. Major M. P. Corkery, Jhansi, has been appointed a specialist in the prevention of disease, and Captain H. M. Nicholls, 6th (Poona) Division, a specialist in ophthalmology. Major C. C. Fleming, D.S.O., is to take up the appointment of instructor at the Royal Army Medical Corps School, Aldershot, on June 13th, in succession to Major J. D. Ferguson, D.S.O.

# A CLINICAL LECTURE

**ON** 

# THE FEEBLE-MINDED AND THEIR CARE. (a)

By GEORGE H. SAVAGE, M.D., F.R.C.P.Lond.,

Consulting Physician and Lecturer on Mental Diseases, Guy's Hospital; Consulting Physician to Earlswood Asylum, &c.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

PART I.

GENTLEMEN,-I feel that to-day's subject is both medical and social, and it is of the very gravest importance. No doubt many—and probably all—of you have seen the very voluminous Report of the Com-mission on the Feeble-minded which was sitting for mission on the Feeble-minded which was sitting for some years, the report consisting of eight volumes, the eighth volume, containing the summary, being the most important. I have felt especial interest in this, for I was requested to contribute an analysis of this report for the *Quarterly Review*. The term "feeble-minded" has to be looked at from two or three very distinct points of view. The Commissioners first accepted the definition of the College of Physicians, which is this: "A feeble-minded person is one who is which is this: "A feeble-minded person is one who is capable of earning a living under favourable circumstances, but is incapable, from mental defect existing from birth or from early age, of competing on equal terms with his normal fellows, of managing himself or his affairs with ordinary prudence." The introduction shows that, first, all persons who, whatever the form or degree of their mental disorder, are unfitted to take part in the struggle of civilised life, are to be considered as feeble-minded. The second principle is that persons suffering from disease should be looked upon rather from the standpoint of disease than the social That, of course, implies a good deal. Some people have said that to have a drunken relation is bad enough, but to have to sympathise with him is still worse. But we have to accept the fact that there are certain feeble-minded people who do not fall into social step, who are unable, unaided, to earn a normal living under normal conditions; therefore, many of them must be treated as sufferers rather than sinners. The third principle is, that if the mentally weak are to be properly recognised and treated, their condition must be reported early. In referring to this subject I have had to point cut the all-importance of early recogmition of the disorder. If any good is to be done you must catch your youths very early. The fourth principle is that the control or treatment must be continued as long as needed. One of the great difficulties we all have who have to deal with the weak-minded or the insane is, that as soon as they have reached a certain standard they are discharged recovered. course, there are many people who have reached the level of reason without being sound. I have said over and over again that because they are perfectly reasonable they are not necessarily perfectly sane, or that they are perfectly fit to return to their old occupations. You might just as well say of a person who has had typhoid fever or some other febrile illness, directly the temperature registers 981° he is fit for anything and everything. In the same way there are many people who are feeble-minded, and yet, up to a certain point, are reasonable. But if in future the suggestions are carried out, people, when they have been recognised as permanently feeble-minded, are not to be returned to society—they are not to be returned, at all events, until it is quite assured that they are trustworthy. That is a very important principle in the consideration of the feeble-minded. The fifth principle is that it is essential that the whole of the insane and weak-minded should be under one definite line of control. At present some weak-minded people come under the Educa-tion Board, certain others fall to the prisons, many others come under the infirmaries. It is suggested

(a) A Lecture delivered at the Polyclinic, London, on Thursday, May 6th, 1909.

that in the future, when it has been clearly defined who the feeble-minded are, they should all be under one definite head. This, perhaps, is a counsel of perfection. We are hardly advanced socialistically enough—or autocratically enough, you might say—to be able to put on one side all those whom we consider not to be strong-minded. There is such a thing as the tyranny of the majority as well as the tyranny of the individual, and at present, desirable as it may be that a large number of these feeble-minded should be put on one side, it is certain that at present we cannot do it, because, according to these principles and according to the definitions, we shall have to include too many as feeble-minded. The Commission definitely point out that every person who is deficient intellectually, but above the grade of idiot and imbecile, but who cannot earn an independent livelihood unaided or uncontrolled, has to be regarded as weak-minded. Such are, of course, intellectually weak-minded. They would also consider, as I shall show presently, that the morally defective—those who tend to dishonesty and vagabondage and to immorality—should be controlled. And that those who are inebriates should certainly be isolated. And, as I shall consider presently, it is not putting on one side temporarily, but, as I read to you just now, the control and treatment must be continued as long as it is needed. And I am afraid the experience of a large number of people is that the control required is life-long. And then, again, epileptics have to be considered; not all epileptics. But the epileptic as a class has to be looked upon as feeble-minded, and it is felt that they certainly should be segregated. The whole principle, then, of social treatment of these weak-minded people is that they should be prevented from propagating. That, of course, is a very wide and large subject, and I suppose it is a subject which some of you would say becomes more social than medical.

medical.

I have pointed out, then, the principles on which the Commission, in investigating these cases, acted; and I have pointed out the nature of the Report, which was carried out in the most thorough way. And yesterday, when I was putting some of these notes down, I could not help noticing in front of me an advertisement—I think from the Cambridge Press—of the "Evolution of the Vertebrates." Naturally, I could not help thinking of the Evolution of the Invertebrates, these backboneless people who are constantly in evidence nowadays. There is no doubt it is of the utmost importance that they should be separated, and that they should be trained.

The first point for our medico-legal consideration is that these are people who are not certifiably insane. Facts observed by yourselves indicating insanity have to be put on your medical certificate. In the majority of these cases there is nothing you can put down as observed by yourself. I believe the time will come when certificates will be modified. Already the certificate required for the detention of an idiot or imbecile differs from that for the ordinary acute lunatic; and there is no doubt that when the feeble-minded are properly cared for, some special form of certificate will be obtained. But the people we are considering are those who are not certifiable. They may be sent to the infirmaries, or they may be sent to the workhouses, but they are not certifiable lunatics. There are the intellectually weak, who are weak all round. There are a large number who were so-called backward as children; and one of the most

serious points is that a very large proportion of distinctly backward children are never anything else. When the question of the education of the feeble-minded was first brought before society, a Duchess of distinction took a deep interest in the matter, and came to the conclusion that the feeble-minded were like many feeble people, that they had only to be trained, and then they would be as good as anybody else. But she soon found that the backward child who was organically backward was deficient, and that you could never make up that deficiency. And it is on that principle that a great deal of this legislation is founded: that the majority of them are permanently weak. They begin with a bad start in life, and are intellectually defective. Already a large provision is being made for those who are physical cripples, but mental cripples need homes, and the help, too, of Lord Mayors.

There are also those who are defective in their senses: blind, deaf, and dumb. But when we come to the next class, the morally defective, we find that very little provision is made, beyond prisons and reformatories. A very large group of so-called wasters are allowed to run amok. It is a common experience of mine to be consulted about a waster with such a history as this:—His grandfather made a huge fortune in some speculation or invention. The next generation went on "guarding the heap." Then comes the next generation, with a reserve of energy which has got no objective, and they go to the bad, in one way or another. And some would say, "A good thing, too; the heap has been raised, and now it has been scattered again." If it were a mere scattering, I would say, "By all means." But the scattering not only damages the waster, but is also injurious to other people, and it is the other people who suffer, much more than does the waster. In setting fire to a building what we have to consider is the other damage which may be done. Just as one saw recently: a small boy amused himself by setting fire to a small piece of furze, and the result is it burns commons for miles. How shall we secure the waster legally? I hardly know, for many of those individuals are intellectual enough, but they may be wanting in what we call the moral sense. The same with inebriates. It is perfectly certain that some inebriates will never be cured, do what you will for and with them. It would be a good thing if they could be put on one side; but I am afraid that at present we cannot do it. I am speaking to those who will each have some influence in regard to legislation in the future, and the question is, What will have to be done with regard to these?

As to epileptics, there are epileptics and epileptics. It has been said that genius, as in Napoleon and Mahomet, may be associated with epilepsy. But it is certain that there are some who might be termed casual epileptics and who are brilliant men, and it would be a sin to look upon them as anything else. The great point is to prevent those epileptics who are constantly epileptic from having offspring. There are those who begin with epileptic fits in early years and should be educated apart. There is a large group who come into the world weak and handicapped from birth, and such never get strong. They are backward, delicate children, and are always subject to rages or fits; they do not develop normally. There are others who, perhaps, reach adolescence or maturity and seem to be like eight-day clocks. They are wound to go eight days, and then they stop. There are certain individuals who seem to be wound up to reach adolescence, and then they break down and become permanently weak-minded. So there are, first, congenitally weak-minded; and, secondly, there are those who are consecutively weak-minded. Some time ago, at Treloar's Cripples' Home, I gave a talk on Mental Cripples, those who were permanently feeble in mind, the mental weakness resulting from some physical disease. A man may be crippled morally after an attack of insanity; he may be crippled morally after an attack of insanity; he may be crippled morally after an attack of insanity; he may be crippled morally after an attack of insanity; or he may be crippled physically after such an attack. Another point, which I think the Commission hardly grasped, is, that if you are to seclude those who are likely to add to the insane population if they marry, there are a large number of people who are regularly insane, just as the epileptic may

have regular fits, so there is a large group of patients who have recurring insanity; they have a cycle; they are depressed, they become wildly excited, then become dull, apathetic, almost weak-minded for a time. They are fairly reasonable, or quite reasonable for a time; then there comes another attack, and another. Are we to consider them as permanently weak-minded people? At present, not.

What is the cause, generally, of this type of mental

What is the cause, generally, of this type of mental weakness? Undoubtedly heredity is the strongest and most dangerous thing. Not only direct inheritance from acute insanity: that is not so severe. I have sometimes said that the danger of an acutely insane parent having an insane child is comparatively little, compared with the certainty of a weak-minded epileptic or physically degenerate having a feeble-minded child. I was obliged to make use of a fairly forced simile. Geniuses, as a rule, do not have geniuses as sons; lunatics frequently do not have lunatics as sons, but weak-minded people do. There is a much graver danger of the transmission of what might be called slight deviations from the normal. It is in accordance with everything which Darwin taught, that it is the slight modifications which are transmitted. Just as genius is an occasional thing, so, fortunately, often insanity is; a genius in a father often does not mean a child genius. But a weak-minded father and a weak-minded mother beget offspring who are easily misled. I see a number of children who are the products of senility: children begotten of very aged fathers, and sometimes of mothers who are near the climacteric. Of course, a healthy old man may have a healthy child. But the lust which is often associated with lack of higher control often has a sequel weak-minded children. A child begotten of a father who has general paralysis of the insane stands a good chance of being imbecile or permanently weak-minded.

Parental vice, such as drink, is a very serious question. Then there is the effect of tuberculous parentage. It is pretty certain that a parent who is physically weak from tuberculous disease may tend to have feeble offspring, and those feeble offspring may be feeble in mind as well as feeble in body.

Another important question which will often be brought before you is that of consanguinity. You will be asked, Is simple consanguinity likely to cause feeble-mindedness? It is a common idea that cousins should never marry. So often am I consulted on this question that I sometimes say I must have one of my rooms labelled "Marriage Bureau." Parents, as a rule, are dead against the marriage of cousins. When you come to review a large number of cases you find the truth is that if there are neuroses in either branch of the families it is a very dangerous thing. If there are neuroses in either family, I should say avoid an important point.

To conclude, then, some neuroses are much To conclude, then, some neuroses are much more readily transmitted than are others. There is a simple all-round feebleness. Such are said to be easily led, to be wanting in will, wanting in adaptability. All these simple things are readily transmitted. Anything allied to epilepsy seems also to be likely to be represented in the next generation by feeble-middeness. One has also to represent the child mindedness. One has also to remember the child who might otherwise have developed all right, but who is affected with some acute disorder in early life, especially if that disorder be a nervous one. care, such may be reared and trained to become useful members of society. One child having convulsions at two years of age, has never been the same child since Many children been the same child since. Many children become weak-minded as a result of some febrile attack children I saw a child the other day who was said to have had I suppose meningitis is sometimes remeningitis. covered from, but many children who have febrile attacks have not meningitis; but they may be left permanently weak-minded. A point which interests me very much is the frequency with which feeble-minded children are found to have had, early in life, some interference with respiration. You get a history that the child was all right until it had measles, followed by bronchitis. A still more common occurrence is to find permanent mental enfeeblement follow whooping-cough. That in itself is a nervous disorder,

and it is a very common thing for me to find, in the history of these weak-minded people, that there has been whooping-cough.

NOTE.—A Chinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by George H. Savage, M.D., F.R.C.P. Lond., Consulting Physician and Lecturer on Mental Diseases, Guy's Hospital; Consulting Physician to Earlswood Asylum, &c. Subject: "The Feeble-Minded and their Care."—PART II.

# ORIGINAL PAPERS.

# BLACK WATER FEVER AND THE INTIMATE PATHOLOGY OF MALARIA. (a)

By Dr. C. A. BENTLEY AND

CAPTAIN S. R. CHRISTOPHERS, Indian Medical Service.

THE malarial origin of Black-water Fever is generally admitted; but there is still a considerable amount of misconception regarding the relationship between malaria and this disease. In the first place it is necessary, of course, to disabuse minds entirely of the idea that in an attack of Black-water Fever we see anything of the nature of a malarial paroxysm; Koch once and for all disposed of such a view.

So in regard to Black-water Fever we can say that

it is never so far as we know a result of one or two attacks of malaria, however severe they may be. It is a new condition, the outcome of malaria under certain circumstances. In the limits of our present paper we cannot do justice to a description of the very definite circumstances in regard to malaria which bring about this condition. We may note only that we require :

(a) A person highly susceptible to malaria, whether this show itself as "fever," or as long-continued infection, with perhaps only vague and uncer-tain symptoms, unrecognised, but none the less dangerous.

(b) Conditions as regards malaria which lead to the certainty of almost daily inoculation with sporozoa. Such conditions are of widespread occurrence on the malarious coast of Africa, but, as

all will probably acknowledge, do not occur in ordinary life in the plains of India.

(c) These conditions must act continuously for a certain time—if exceedingly intense, or in the case of a very susceptible person during six case of a very susceptible person during six months, or in very rare instances three months, but usually for a period of about eighteen months or two years.

DIFFERENT SPECIES OF PARASITE.

Let us consider for a moment some of the special features of the different species of the malaria para-

we are concerned with three species:—The Quartan, the Simple or Benign Tertian, the Malignant Tertian.

Everyone is familiar with the differences between these three types and the broader characteristics of the respective infections produced by them. But there are certain points which appear to have a special importance in connection with the matter under discussion, and it is necessary to refer to them, particularly as the study of malaria is not often approached from

the point of view we are indicating.

In malignant tertian infections some of the most noticeable features of the condition are:

- The absence from the peripheral blood of sporulating bodies, and the disappearance of parasites from this situation once they have reached a certain stage of their existence.
- The tendency for the accumulation of the infected corpuscles in the visceral capillaries.
- (a) Paper read before the Indian Medical Congress at Bombay,  $F_{\rm cbruary, 1909}$ .

- (c) The frequently recorded marked alteration of the infected red cells-(globuli rossi change)
- Specially active phagocytosis of infected cells.
- The great tendency for infections by this species of parasite to produce pernicious symptoms, often simulating definite organic disease as of the brain (comatose and delirious forms), the intestinal system (algid, choleraic and dysenteric forms), the lungs (pneumonic form), and, according to some observers, other manifestations such as a form of pleurisy, etc.

  In infections by the quartan and simple tertian parasites, on the other hand, we find:—

  (a) Sporulating bodies appear very frequently in the peripheral circulation

peripheral circulation.

(b) There is not the same tendency for infected red corpuscles to be held up in the visceral capil-

(c) Phagocytosis of infected red cells is exceedingly rare, Thayer stating that he has never observed

(d) Pernicious attacks are rarely if ever encountered in the course of infection by either of these two species of parasite.

Are the different phenomena observable in the case of infections by the malignant tertian parasite, for example, inter-related? And, again, are the different effects produced by each species of parasite due merely to the characteristic behaviour of these parasites, or is there some fundamental pathological principle underlying them all?

BLOOD DESTRUCTION.

Let us before answering these questions turn to the consideration of certain data connected with blood destruction in the body. If we add some hæmolytic uestruction in the pody. It we add some hæmolytic agent to a suspension of red blood corpuscles in vitro, we shall under suitable conditions produce a solution of the cells. This being so one is tempted to think that the profound destruction that may follow the injection of the conditions of the condition of th the injection of a hæmolytic agent into the body, may be due to a simple solution of the red cells, resulting from the direct action of this hæmolytic body, such as occurs in the test-tube. But this conception does not accord with the facts.

By injecting a goat with dog's blood we prepared in the ordinary manner a hæmolytic serum which, under suitable conditions, showed a strong solvent action for dog's corpuscles. The injection of a large dose of this serum into dogs was followed by a rapid, uose or mis serum into dogs was followed by a rapid, profound and progressive anæmia, resulting in death. Here, then, we might be tempted to suppose that there had been a solution of the dog's red cells. In the case of many animals, however, in spite of extraordinary anæmia brought about within a few hours by the toric serum, there was no evidence of red cell solutions. ordinary anamia prought about within a few hours yethe toxic serum, there was no evidence of red cell solution. Hæmoglobinuria did not occur, nor did a careful examination of the blood show the presence of hæmoglobinæmia or shadow corpuscles. Moreover, though the tissues on post-mortem examination show great pallor, there was none of the yellow staining characteristic of the condition mentioned later, in which solution of the red cells had actually occurred. Further examination of the organs showed that the rapid and enormous blood destruction was not of the nature of solution at all, but was due to an extraordinary phagocytosis of red corpuscles and the holding up of these blood elements in the capillaries, notably those of the spleen and liver. The condition of affairs in the different experiments could be seen to vary from some congestion of an organ associated with red-cell phagocytosis to the most extraordinary Moreover, hæmoglobinæmia or shadow corpuscles. with red-cell phagocytosis to the most extraordinary condition where the whole spleen was converted into

a mass resembling a thrombus.

But by a regulation of the dose of the serum we found that another result could be obtained. A lesser dose produced, as before, severe and rapidly progressive anæmia with a similar holding-up and phagocy-but and the visceral capillaries. But very tosis of red cells in the visceral capillaries. But very often when the anæmia had progressed for twentyfour hours or more there supervened a new phase; for the first time the plasma now showed free hæmoglobin. the urine became hæmoglobinous, and the tissues after death showed the characteristic yellow staining so well seen in Black-water Fever. In this phase, too, in blood from the hepatic and renal vessels we found shoals of stromata and decolorised red cells.

Two Distinct Processes.

Two distinct processes may result, therefore, from the action of a hæmolytic serum in vivo:—

the action of a hæmolytic serum in vivo:—

(a) An easily produced and constant effect due to the holding-up in the organs and ultimate phagocytosis of red cells;

(b) And a condition which may or may not supervene, characterised by actual solution of the cells within the blood stream, the accompanying hæmoglobinæmia being followed by the occur-

rence of hæmoglobinuria.

For convenience of description and because at the time no suitable names existed for these two newly-recognised processes, we termed them, respectively, "Erythro-katalysis" and "Lysæmia." These terms, although not perfect, appear to answer their purpose

for the present.

Why then, we may now ask, do we not get hæmoglobinuria in the course of an ordinary attack of malaria, however severe? Because we can say, it must be that the destruction of red cells in malignant tertian malaria is not due to "lysæmia," a condition which would produce Black-water Fever, but to "erythro-katalysis." How far erythro-katalysis is concerned in blood destruction by simple tertian and quartan malaria we do not know, but here we seem to have another factor, for in these infections disruption of the red cell occurs only when it no longer contains an appreciable amount of hæmoglobin. There appears, therefore, to be little doubt that the action exerted by the malignant tertian parasite upon the red cells differs in a marked degree from that exhibited by the parasites of the other two species. And this peculiar action is chiefly demonstrated by the induction of a condition which renders the corpuscles especially susceptible to destruction by erythro-katalysis, so leading more than in the other infections to a holding-up of infected cells in the visceral capillaries.

The tendency towards an extensive phagocytosis of damaged cells is also in accordance with the general pathological principle. The absence of sporulating bodies is also obviously due to the same; and we could, if time were not pressing, show that the change in globuline rossi corpuscles, a change which we have noted and which is well known to be very common in malignant tertian malaria, is a condition exactly resembling that brought about by erythro-katalytic terrian such as well as the contraction of the same of the same; and we have the same of the same; and we have the same of the same; and we have the same of the same; and we have the same of the same of the same; and we have the same of the same; and we have the same of t

toxins, such as we have used experimentally.
